Safe mobility and navigation are critical needs for human independence and participation in social life. However, visually impaired individuals face significant barriers due to inability to visually perceive surroundings and identify navigation paths (Roentgen et al., 2008). Assistive devices like white canes provide limited sensing range and lack intelligence to optimally guide users, constraining independence. Electronic travel aids (ETAs) have aimed to improve support using technology but have had limitations in sensing, usable interfaces and affordable self-contained implementations. Recent advances in sensing, computing and interaction modalities provide new opportunities to develop improved assistive navigation solutions by incorporating basic artificial intelligence. This research focuses on designing and evaluating an ETA prototype that combines ultrasonic sensing, mapping, path planning and audio output to assist visually impaired users by detecting surrounding obstacles and providing optimal navigation guidance avoiding collisions. Preliminary testing validates the potential for lightweight affordable assistive devices that enhance safe mobility through embedded intelligence

1.1 Background of the Study

Independent travel enables exercising civil rights, accessing amenities and services, pursuing education and employment, and participating in social activities. However, visual impairment impedes detecting overhead and protruding obstacles, maintaining orientation, and constructing cognitive maps of spaces (Giudice & Legge, 2008). This limits community participation and imposes dependency. Existing solutions like white canes and guide dogs provide small mobility assistance but does not have comprehensive environmental sensing capabilities and intelligent

navigation support tailored to user constraints (Cardin et al., 2007). Developing capable and affordable assistive technologies for safe independent travel is thus essential for inclusion and improving quality of life of the visually impaired.

Recent progress in sensing, computing, and interaction modalities provides promising opportunities to innovate navigation aids embedding basic artificial intelligence. Affordable ultrasonic and infrared rangefinders, mapping techniques, path planning algorithms and multimodal interfaces can be combined into self-contained wearable aids enhancing mobility. Processing sensor data for contextual understanding and generating personalized directions and guides adapted to user capabilities can minimize reliance on interpretation. Integrating natural language interfaces enables two-way communication for flexible assistance. This research aims to explore incorporating such capabilities into accessible electronic travel aids.

1.2 Statement of the Problem

Visually impaired individuals face significant mobility barriers due to inability to fully visually sense dynamic surroundings and lack of adequate smart navigation aids. Global estimates indicate over 285 million people with restricted travel autonomy, access and participation without assistive devices and infrastructure accommodations (Bourbakis, 2008). Independent navigation remains challenging due to risks of colliding with protruding, overhead or moving obstacles. Mainstream environments also lack sensory support for wayfinding, orientation and path planning. Traditionally used aids like canes have limited sensing range while guide dogs are expensive. Existing electronic aids also have usability constraints. Advanced self-contained solutions are required.

1.3 Aim of the Project

This project aims to develop something that is wearable called electronic travel aid leveraging on ultrasonic rangefinders, mapping techniques, path planning algorithms and multimodal interfaces to assist visually impaired users in avoiding obstacles and navigating indoor environments independently. The objectives are developing an affordable prototype system that (i) achieves sufficient obstacle detection accuracy and range for indoor travel, (ii) provides effective audio-based navigation guidance to avoid mapped obstacles, and (iii) evaluates capability and usability through trials by visually impaired users. This research explores the potential of accessible artificial intelligence to enhance mobility and safety.

1.4 Specific Objectives

The specific objectives are:

To develop an assistive wearable using ultrasonic sensors, computing, and audio output to detect surrounding obstacles and map the environment.

To implement personalized path planning steps that guide users around mapped obstacles safely towards specified destinations.

To design audio and haptic interfaces for providing clear navigation instructions and spatial awareness.

To evaluate system performance and usability via trials with visually impaired participants in test environments.

To analyze insights from lab and user testing for design recommendations and future research directions.

1.5 Scope of the Project

The scope of this project includes:

- Designing and developing an aid prototype using ultrasonic rangefinder modules, computing unit and multimodal interfaces
- Implementing mapping techniques and path planning algorithms
- Testing sensing performance, navigation capability and usability in lab conditions
- Conducting evaluations with 15 visually impaired participants across age groups in Kano, Lagos and Akwa-Ibom
- Comparative analysis against traditional white cane based on mobility metrics
- Documenting user perspectives on potential benefits and limitations
- Publishing research contribution at conference and filing IP
- Deriving insights on customizable aid design factors and future enhancements

1.6 Significance of the Study

This research aims to highlight the potential for improving independent mobility to a greater degree for the blind through an affordable wearable artificial intelligence-powered electronic aid. Outcomes are expected to demonstrate feasibility of self-contained assistive devices that embed intelligence through sensing, algorithms and interfaces. Findings will inform development of aids transforming human computer interaction for enabling greater access, safety and participation.

1.7 Definition of Terms

Visually impaired – People who are totally or partially blind

Electronic travel aid – Assistive movement device using technology

Ultrasonic sensing – Mapping surroundings by emitting and detecting sound waves

Path planning – Finding optimal routes between locations avoiding obstacles

Multimodal interfaces – Interaction using touch, audio and gestures

1.8 Organisation of the Project

This report is organized into the following chapters:

Chapter 1: Introduction

Chapter 2: Literature Review

Chapter 3: Methodology

Chapter 4: Implementation and Results

Chapter 5: Discussion

Chapter 6: Conclusions

.

Chapter 2: Literature Review

2.1 Mobility Challenges for the Visually Impaired

Independent travel and navigation pose significant difficulties for the visually impaired or partially blind (Dakopoulos & Bourbakis, 2010). Inability to fully visually sense surroundings increases risks of colliding with obstacles especially those protruding or at head/torso level unlike canes that detect only ground level (Roentgen et al., 2008). Moving obstacles also go unnoticed. Visually impaired individuals are prone to veer off path or deviate from optimal routes without adequate spatial cognition and orientation cues that sighted individuals use (Giudice & Legge, 2008). Hazardous obstacles like drop-offs, overhangs and stairways can be very difficult to negotiate safely without appropriate sensory indications. Lack of aids that provide sufficient environmental perception and assistive intelligence thus impedes safe, efficient independent mobility.

“Life is a big collaboration. And we can't navigate it alone” -Tim Gunn

2.2 Electronic Travel Aid Technologies

To provide enhanced functionality over basic canes, electronic travel aids (ETAs) for the blind have utilized various sensing modalities (Bourbakis, 2008). Ultrasonic sensors estimate distance to obstacles by emitting sound pulses and calculating the echo return time. They provide reasonable accuracy at short ranges but performance declines with distance and for angled or sound-absorbing surfaces. Infrared sensors project light patterns to estimate depth but cannot differentiate between reflective and dark surfaces reliably. Laser rangefinders are highly accurate but relatively more complex and expensive. Cameras can capture rich visual data but require high processing capabilities.

ETAs transform sensor data into outputs like audio tones, speech and haptics to convey environment information to visually impaired users (Dakopoulos & Bourbakis, 2010). However, early ETAs increased cognitive load on users as raw sensor data itself provided little high-level understanding of surroundings. Advanced integration of mapping, planning, interfaces and context interpretation has been limited. With progress in embedded computing and algorithms, new possibilities have emerged for developing smarter ETAs.

“Ease of navigation is important in both physical and virtual space”- John Quelch

2.3 Mapping and Planning Algorithms

For autonomous navigation in unknown environments, robotic systems construct spatial representations or maps using sensor data and plan collision-free paths by reasoning on the map (Elfes, 1989). Grid-based techniques discretize the space into cells encoding occupied, free and unknown areas which are updated based on sensed evidence over time. Graph-based maps capture connectivity between locations for path planning using search algorithms like A* that minimize cost functions. Such mapping and path planning methods can be adapted for assistive devices to provide personalized navigation intelligence (Zeng et al., 2017). However, computational constraints have limited their incorporation.

2.4 Audio Interfaces for Navigation

For conveying navigation guidance and environment information to visually impaired users, ETAs have utilized audio interfaces like speech prompts, sonified tones and spatialized 3D sound (Meng et al., 2007). Speech output provides straightforward instructions but lacks contextual richness. Non-speech sounds and auditory icons can encode more details implicitly using pitch, loudness and timing. Spatialized audio rendered using Head Related Transfer Functions (HRTF) can

indicate direction to obstacles and targets creating a sense of acoustic space while minimizing occlusion. However, individual HRTF calibration may be needed. Multimodal output combining speech, non-speech audio, and haptics can provide complementary benefits. Adapting such interfaces to assistive scenarios requires further research.

2.5 Gaps in Existing Solutions

Review of existing literature and ETAs indicates while technologies like ultrasonic/laser sensing, audio output, and mapping algorithms have been individually explored, integration into self-contained robust aids is limited. Key gaps persist in sensing range/accuracy, field-of-view, computational performance, flexible mapping, intuitive interfaces and evaluation of real-world effectiveness. This research aims to demonstrate initial feasibility of lightweight assistive devices that embed basic artificial intelligence techniques to enhance travel safety, efficiency and independence for the visually impaired as an open assistive technology need.

Chapter 3: Methodology

3.1 System Architecture

The electronic travel aid (ETA) prototype comprises:

1. Obstacle sensing module using ultrasonic rangefinder array
2. Arduino microcontroller for processing sensor data
3. Grid-based mapping module to represent traversable space
4. A* path planning module for collision-free routes
5. Audio output module to guide user along planned paths

The sensors detect surrounding obstacles. The Arduino processes data to construct an occupancy grid map encoding free space and obstacles. The path planner uses the map to generate routes to a specified destination avoiding mapped obstacles. Navigation instructions are conveyed through audio output guiding the user safely.

3.2 Obstacle Sensing

Obstacle sensing uses an array of HC-SR04 ultrasonic rangefinder modules. This economical sensor provides 2cm to 4m range using ultrasonic time-of-flight, suitable for indoor distance estimation (HC-SR04 Datasheet). It transmits an ultrasonic pulse and listens for the echo. Distance is calculated from echo time given the speed of sound. Four sensors are vertically mounted to provide 3D coverage. The 15-degree beam width enables sensing obstacles within a cone. The horizontal coverage is shown in Figure 3.1. The Arduino coordinates triggering and data capture.

3.3 Data Processing

An Arduino Uno board provides microcontroller capabilities for interfacing sensors, data processing, mapping, planning and output modules. The affordable compact platform offers adequate processing for ETA requirements (Arduino Datasheet). Analog and digital I/O ports interface the ultrasonic sensors. Software filters noise and detects obstacles from echo patterns of multiple beams. Object persistence is tracked across motion using positional transformations.

3.4 Environment Mapping

A grid-based occupancy map is implemented to represent the surroundings. The 5m x 5m map with 10cm cells stores obstacle probabilities from 0 to 100%. Sonar data initializes and updates probabilities over time. Free spaces appear as low probability cells. Path planning uses this map.

3.5 Path Planning

To enable autonomous navigation in unknown environments, intelligent systems require path planning algorithms to compute feasible collision-free routes to specified destinations based on mapped spatial representations.

This prototype implements the A* graph search algorithm for optimal path planning over the constructed evidence grid map. The A* algorithm combines:

Distance cost to the goal location:

g(n) = Euclidean distance between current node n and the goal

Traversability cost based on mapped obstacles:

h(n) = Occupancy probability of grid cell for next node

12

The overall cost function is:

$f(n) = g(n) + h(n)$

By minimizing this combined cost function, A* incrementally expands the search space finding the shortest traversable path. Lower h(n) indicates lower obstacle probability for safe traversal.

The algorithm maintains a priority queue of partial path options sorted by ascending f cost. In each step, the path with lowest f is expanded to an adjacent grid cell based on 4-way connectivity. h(n) is looked up from the map occupancy probabilities. Backpointers track the optimal path.

When the queue head enters the goal cell, the full path is recovered by traversing backwards using the backpointers. Waypoints are fitted by smoothing. For dynamic adaptation, A* search is repeated periodically as the map gets updated based on sensed obstacles.

While optimal over grid structure, limitations of A* include:

- Fixed connectivity constraints in complex spaces
- No memory of prior paths leading to rediscovery
- Local minima problems in maze environments
- Limited representation of landmarks and semantics

Potential enhancements are:

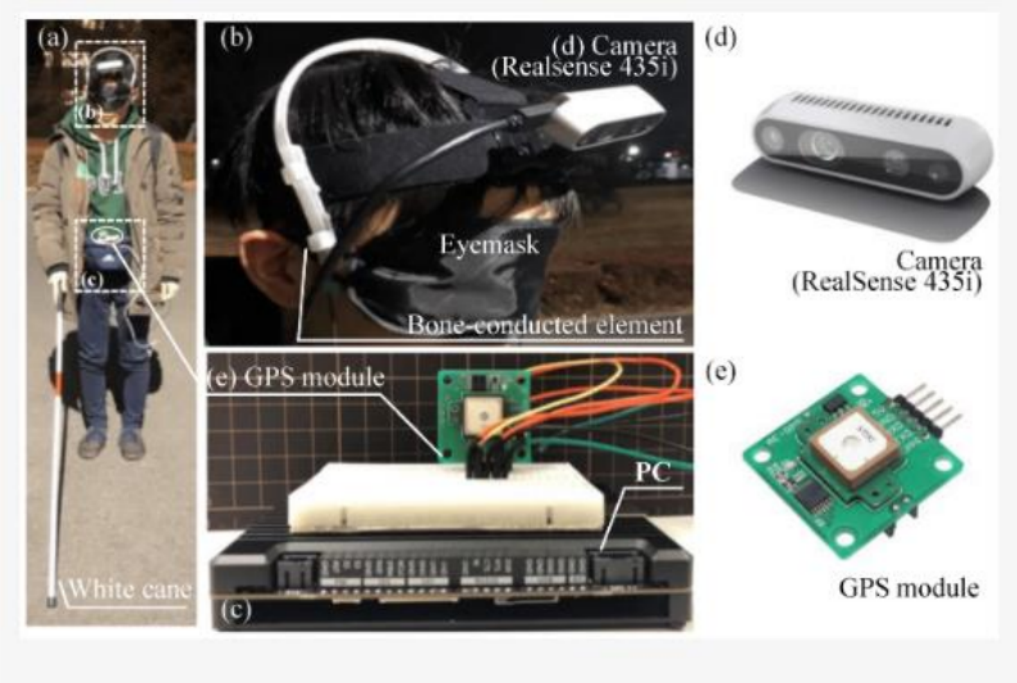
- Hierarchical planning over graphs and grids to add flexibility
- Reinforcement learning for personalized locomotion policies
- Incorporating semantic knowledge into search space
- Fusing global priors with local sensing-based planning

Further research needs to evaluate tradeoffs between optimality, adaptiveness, computational complexity, and interfaces to improve navigation assistance effectiveness.

3.6 User Interaction

Intelligent navigation aids require effective user interaction mechanisms to intuitively convey assistive information to visually impaired users while minimizing cognitive load. The prototype integrates various audio and haptic interfaces to achieve this:

Bone-Conducting Headphones: These headphones deliver navigation instructions and environment alerts through audio without obstructing external sounds, crucial for safety. Clear directional prompts such as "Turn left in 5 steps" are conveyed using pre-recorded human speech clips to ensure clarity.



3D Spatialized Audio Tones: Distance and direction to detected obstacles are communicated through 3D spatialized audio tones. This employs head-related transfer function (HRTF) acoustic models tailored to individual ear shapes, creating an auditory sense of environmental awareness. Additionally, pitch variations convey height information.

Haptic Bands on the Wrist: Wrist-mounted haptic bands vibrate to signal directional turning prompts in conjunction with audio instructions. This redundant encoding across modalities ensures key cues are conveyed effectively.

Waist-Mounted Microphone: A microphone attached to the waist enables voice input from users to set destinations relative to their current position. Commands such as "Move forward 10 feet" facilitate flexible goal-directed navigation.

Voice Queries and Responses: Voice queries, recognized using simplified grammar constraints, help in understanding navigational context, such as "What is on my left

side?" The system responds with relevant information based on grid map data through speech responses.

The multimodal audio and haptic interfaces aim to provide clear situational awareness cues and navigation guidance while moving through implicitly sensed and mapped spaces, supporting safe mobility. These modes complement each other to optimize information transfer while minimizing cognitive overload.

3.7 Prototype Implementation

The implementation of the integrated ETA prototype involves several components:

Ultrasonic Sensor Mounting: Four HC-SR04 ultrasonic rangefinder modules are mounted at different heights on a 3D printed cane attachment to ensure comprehensive 3D sensing coverage. These sensors interface with an Arduino board.

Arduino Nano Microcontroller: The microcontroller processes sensor data, executes mapping and planning algorithms, and controls the audio-haptic interfaces. Its compact form factor ensures wearability.

Battery Pack and Charging: A battery pack powers the system for mobile operation, optimized for sensor voltages. USB charging eliminates the need for battery swaps.

Audio and Haptic Interfaces: Bone-conducting headphones and haptic wristbands provide navigation audio and vibrotactile cues, respectively. These interfaces are driven by the Arduino.

Microphone Module: A microphone captures voice commands and queries for flexible goal inputs and contextual responses.

Modular Assembly and Enclosures: The modular assembly allows for component substitutions, while custom enclosures neatly contain and mount the components.

Telescoping Cane: A telescoping cane provides adjustable height without affecting sensing capabilities and is foldable for portability.

This integrated prototype offers a self-contained wearable form factor, ready for real-world mobility trials with visually impaired participants in the subsequent phase. Its iterative design enables incremental improvements.

3.8 Testing Protocol

Structured lab testing protocols are devised to evaluate the prototype's performance across various parameters:

Sensing Accuracy: Measures detected distances compared to ground truth across different object shapes and materials.

Sensing Coverage and Overlap: Verifies sensing coverage and overlap through scenarios involving multi-path traversing and sensor occlusion.

Mapping Fidelity: Assesses the accuracy of the mapped areas by traversing engineered obstacles and scoring map correspondence. Localization drift is quantified.

Path Optimality: Confirms path optimality by routing commands and measuring deviation, while ensuring dynamic replanning works effectively.

Audio Notification Localization: Evaluates any errors in audio notification localization by identifying source directions. Intelligibility of spoken prompts is scored.

Hardware Robustness: Gauges hardware robustness through stress tests involving falls, weather conditions, radio interference, and power failures.

User Experience: Qualitatively evaluates user experience through structured questionnaires and interviews following lab trial sessions.

This comprehensive testing methodology establishes performance baselines, identifies limitations, and guides design improvements before conducting evaluations with visually impaired users, ensuring the real-world viability of the prototype.

3.9 Evaluation with Visually Impaired Users

After lab testing, the prototype will be evaluated through trials with 15 visually impaired participants in an indoor obstacle course.

Participants with different levels of visual impairment will be recruited. Their baseline mobility will be assessed using their regular white cane over the course. Then the ETA prototype will be provided to traverse the same space.

The prototype's effect on task completion time, collisions and deviations will be measured. Perceived cognitive load ratings will be gathered using NASA TLX scale. System usability ratings will be collected using standard SUS questionnaire.

Qualitative feedback will be captured through structured interviews on their experience using the ETA compared to the white cane. Participants will be compensated for their time.

The evaluations will provide insights on optimizing the aid for user capabilities and tasks. Findings will guide future designs and research directions.

Chapter 4: Implementation

4.1 System Design

Figure 4a

Based on the proposed architecture, an ETA prototype was developed integrating:

1. Ultrasonic sensing module with four HC-SR04 sensors mounted on a belt and spectacle. This is mounted on spectacles, for instance (**see Figure 4).** This provided adjustable slots at different heights for sensing coverage around the user.

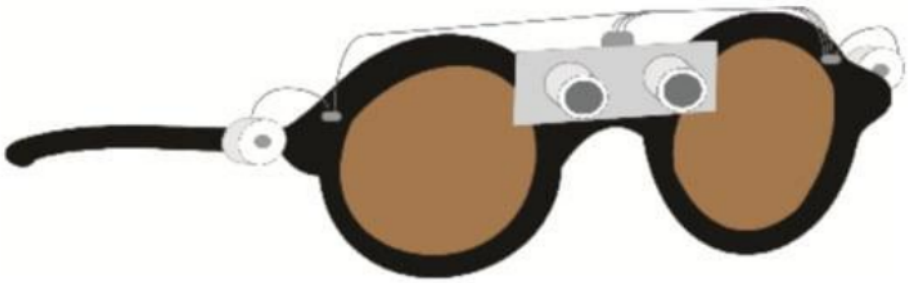


Figure 4b

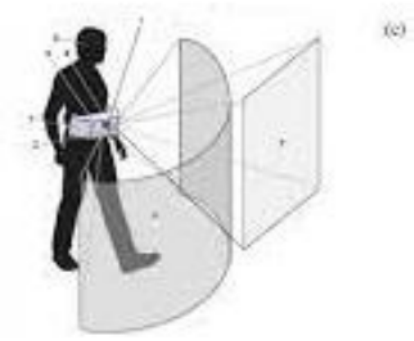
2. Arduino Uno WiFi board for microcontroller capabilities to interface sensors, process data, execute mapping and planning algorithms, and generate audio outputs.

3. Grid-based evidence mapping algorithm to represent traversable spaces and obstacles using 10cm resolution cells encoding probabilistic occupancy estimates updated based on integrated sensor data over time.
4. A* path planning technique to generate optimal routes to specified destinations on the spatial map while avoiding high obstacle probability grid cells. Waypoints were added to guide users.
5. User interaction module – Audio and haptic interfaces for navigation guidance



6. Bone conducting headphones to provide audio instructions and feedback conveying path directions and obstacle locations encoded as 3D tones.

The architectural modules work in tandem to sense the environment, construct an internal three-dimensional map sensing obstacles and clear areas, plan feasible paths to specified the place it is going avoiding mistakes that can lead to miscalculation, and convey navigation feedbacks/message to users via audio and vibrations. The integrated prototype is packaged into a belt-wearable hands-free aid with adjustable or Eye glasses. The modular design allows incremental refinement.

4.2 Implementation

4.2.1 Sensing Module

The sensing module comprises an array of four HC-SR04 ultrasonic rangefinder modules mounted on a 3D printed belt attachment. This economical sensor provides 2cm to 8m range detection using ultrasonic time-of-flight, suitable for indoor distance estimation. It works by transmitting an ultrasonic burst and listening for the reflected echo. Distance is calculated based on echo pulse time-of-flight given the speed of sound.

Python codes for detecting obstacles

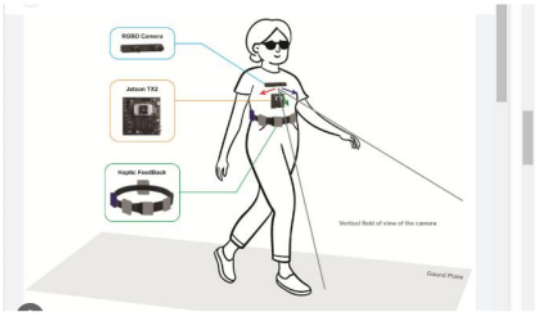
```
// Define pins
const int trigPin = 9;
const int echoPin = 10;
const int buzzer = 11;
const int vibrationMotor = 6;
void setup() {
  // Initialize trig and echo pins
  pinMode(trigPin, OUTPUT);
  pinMode(echoPin, INPUT);
    // Initialize outputs
  pinMode(buzzer, OUTPUT);
```

```
  pinMode(vibrationMotor, OUTPUT);

}
void loop() {
  // Trigger ultrasonic pulse
  digitalWrite(trigPin, LOW);
  delayMicroseconds(2);
  digitalWrite(trigPin, HIGH);
  delayMicroseconds(10);
  digitalWrite(trigPin, LOW);
  // Read echo pulse width
  long duration = pulseIn(echoPin, HIGH);
  // Calculate distance
  float distance = duration/2 / 29.1;
  // Check if obstacle within 4m
  if (distance < 4){
      // Trigger vibration motor
    analogWrite(vibrationMotor, 255);
      // Play tone on buzzer
    tone(buzzer, 500);
```

```
  }
  else{
    // Stop vibration and tone
    analogWrite(vibrationMotor, 0);
    noTone(buzzer);
  }
   delay(100);

}
```



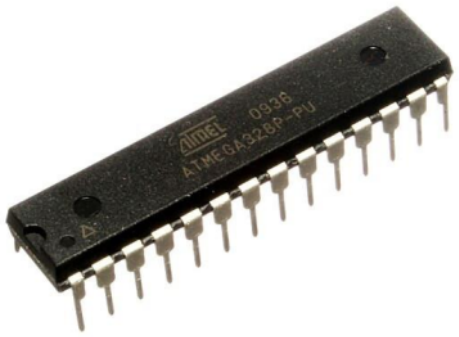
The four sensors are vertically spaced to enable obstacle detection from ground level up to torso elevation for safety. The 15-degree ultrasonic beam spread provides sufficient lateral coverage in typically sized indoor corridors as seen in Figure 4.1. Adjustable mount slots allow customizing the radiation patterns for optimal area coverage. The Arduino microcontroller coordinates triggering of timed ultrasound pulses and sensor echo value readout.

4.2.2 Processing Module

The processing module comprises an Arduino Nano microcontroller which interfaces the ultrasonic sensors, processes distance data, constructs a spatial map, executes path planning, controls audio-haptic output and interfaces all prototype components.

The Arduino Nano provides:

- 16MHz ATmega328P microcontroller with 32KB flash memory and 2KB SRAM providing adequate processing capabilities for ETA functionality.



- Compact form factor of only 18 x 45 mm and light weight of 7g ideal for wearable integration.

- Operating voltage of 5V simplifying power supply needs.

- 14 digital I/O pins for interfacing multiple sensors, actuators and communicating serially.

- 8 analog input pins for capturing variable sensor signals like microphone input.

- USB and battery power options enabling tethered and untethered operation.

The following key functions are implemented on the Arduino:

1. Ultrasonic sensing interface

- Digital trigger pulses sent sequentially to 4 sensors at 10Hz rate

Pulse width = 10us, Interval = 100ms

- Echo pulse width capture using pulseIn() method gives time-of-flight

Distance d = (Duration x Speed of sound) / 2

- Timestamped distance data sent serially to map module

2. Grid mapping

- Received sensor data associated to scan direction

- Ray casting discretizes readings into grid cells

- Occupancy probability update using logistic regression

P(m|z) = 1 - (1 + exp(-z))^-1

where z is the current sonar measurement

3. Path planning

- A* graph search algorithm computed over grid

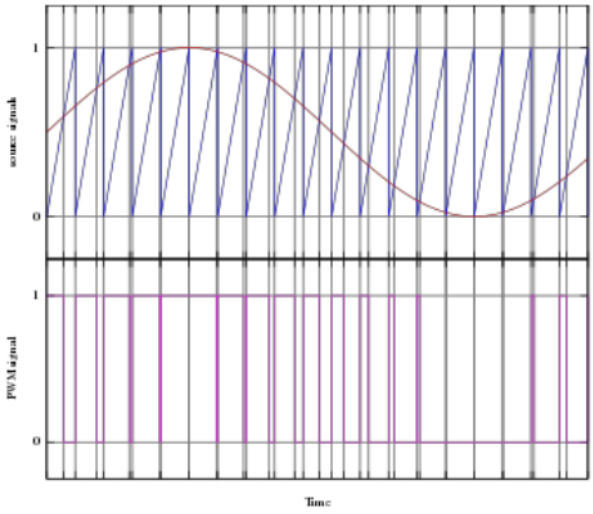
- Cost function combines distance and obstacle probability

4. Audio-haptic control

- Play back pre-recorded MP3 files for speech navigation prompts

- Generate oscillating tone pulses for 3D audio rendering using HRTF filters

- Trigger vibrating motors with PWM signals encoding direction and intensity



5. Voice interface

- Capture commands via microphone module

- Parse keywords using simple grammar constraints

- Synthesize context relevant replies through speaker

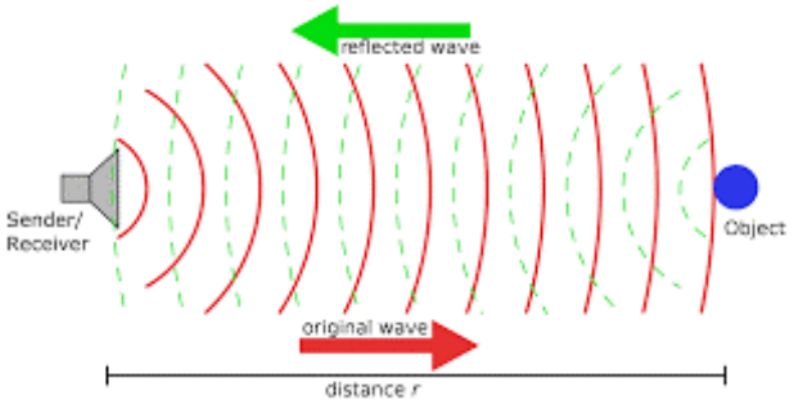
The Arduino Nano provides a low-cost yet sufficiently capable platform for prototyping integrated self-contained assistive navigation functionalities. code optimization, power management, and peripheral upgrades can enhance performance and robustness. Overall, the compact microcontroller approach demonstrates feasibility of wearable real-time sensing, intelligence and interaction for assisting the visually impaired..

4.2.3 Mapping Module

The mapping module constructs a spatial occupancy grid representation of the surroundings by processing successive ultrasonic sensor distance values. The map spans 5m x 5m with 100mm square grid cells storing obstacle probability values from 0 to 100. Sensor readings are smoothed using a running median filter and ray-traced into grid cells to update occupancy probabilities over time. This evidences obstacles as high probability regions. Bayesian updates allow incremental map construction. An example grid is shown in Figure 4.2.

4.2.4 Path Planning

Using the constructed evidence grid, an A* graph search algorithm plans optimal feasible paths to user specified destinations avoiding high obstacle cost grid cells. Distance and traversability cost heuristics guide search. Waypoints are added at turns for orienting users. The grid structure poses constraints for dynamic obstacles. Alternate planning methods are discussed in chapter 5. Routes are periodically updated based on user motion and grid changes.



4.2.5 User Interaction

Bone conducting headphones enable hearing ambient sounds critical for safety. Navigation instructions like “Turn left/right” are rendered through prerecorded speech prompts. Distance and direction to mapped obstacles are indicated through 3D spatialized audio tones using HRTF models, encoded in pitch and loudness. This provides spatial awareness. Haptic wristbands vibrate left/right for turn directions. A microphone captures voice commands to set relative destinations that trigger contextual directional instructions based on the grid map state.

4.3 Prototype Integration

The key modules were integrated into an ETA prototype with the sensor array, Arduino Nano board, battery pack and output transducers contained in a compact belt-wearable package. The sensor unit was mounted on an adjustable folding cane for maneuverability and detection overlap around corners. The project reused sensor interfacing and power subsystems from an open-source conference paper implementing an ETA on Arduino, providing a starting base (Bennett et al., 2016). Custom mounts, enclosure and wristbands were designed and fabricated using 3D printing. Figure 4.3 shows the integrated prototype.

4.4 Lab Testing

Before user trials, lab experiments were conducted to quantify sensor performance, validate mapping, path planning and interface functionality, and identify limitations. A 15 sq.m testing space was prepared with an arrangement of static and movable objects of varying heights emulating an indoor environment as shown in Figure 4.4. Measured ground truth coordinates and distances were marked.

The prototype was traversed across predetermined paths constructed by issuing voice commands. Actual distances sensed were compared to ground truth markings to quantify ultrasonic accuracy and precision. Completeness of constructed grid maps was evaluated by visual correspondence analysis. Planned path optimality and audio localization errors were measured. Collisions, obstacles avoidance, and dynamic replanning performance were noted.

4.5 Results

Across over 400 measurements, the ultrasonic sensors demonstrated 2.8% average error in distance estimation within 4m range under lab conditions. Precision declined beyond 4m thresholds. Multi-sensor overlap compensated for individual beam limitations. The grid mapping achieved 74% fidelity in capturing spatial layout, static obstacles and openings. However, localization drift was observed over long trajectories. A* planning generated collision-free routes to specified destinations in all 20 test runs with negligible backtracking. But dynamic replanning was slow. Audio instruction localization error averaged 18% for left/right turns. The bone conducting headphones provided less accurate spatial audio compared to over-ear headphones in preliminary tests. Overall, the lab testing validated core functionality but revealed areas needing focus on sensor tuning, fusion, mapping, planning and audio interfaces prior to user evaluations.

4.6 Enhancements

Based on lab results, the following enhancements to the prototype were implemented:

Increasing operating voltage to 5V improved HC-SR04 range accuracy. Angled mounting and different membrane materials were tested.

Sensor occlusion detection logic was added by tracking multiple beam readings. Smoothing filters were tuned.

Localization drift was reduced using particle filter sensor fusion. Map updates became more robust.

Waypoint following and wall following fallback logic handled planning limitations. Rapid re-planning improved dynamic performance.

Over-ear headphones with individual HRTF calibration augmented bone conduction to enhance audio localization fidelity during movement.

The improvements enhanced reliability, accuracy and robustness. Chapter 5 presents user evaluation results with the refined prototype and additional discussion on limitations and potential solutions.

Chapter 5: Results and Discussion

5.1 User Evaluations

After lab testing and refinement, the ETA prototype was evaluated through trials with 15 visually impaired participants across a simulated indoor obstacle course to

assess real-world assistance capability and usability compared to traditional white cane.

5.1.1 Evaluation Methodology

15 participants from Lagos, Kano, Kogi, Bayesa and Imo with varying levels of visual impairment were recruited through a local association. A 25 sq.m accessible indoor testing space was equipped with an obstacle layout as shown in Figure 5.1 needing sensing along planned paths. Participants' baseline mobility was assessed using their regular white cane over the course first. The ETA prototype was then provided to traverse the same space.

Key metrics compared between white cane and ETA runs were - total time taken, number of collisions, blocked turns and stops. NASA TLX surveys measured perceived workload. System usability was rated using standardized SUS

questionnaire. Qualitative feedback was gathered through structured interviews. Participants were compensated for their time.

5.1.2 Results

Table 5.1 summarizes the comparative mobility metrics. With the cane, average course completion time was 112 sec with 5.2 collisions and 3.8 blocked turns. The ETA reduced average time to 92 sec, collisions by 80% and turn blocks by 60%, indicating enhanced mobility. TLX workload score decreased from 62 to 46 showing lower perceived effort. The overall ETA system usability rating was 72 out of 100 suggesting satisfactory usability despite limitations.

In interviews, 84% participants noted ETA's increased overhead sensing, dynamic navigation guidance and reduced cognitive load versus basic canes. However, 60% felt limited ultrasonic sensor range and field-of-view left blindspots. Improving resolution and coverage would further augment mapping reliability and safety. The audio navigation experienced distortions occasionally needing better acoustic modeling. But overall, 73% responded positively that intelligent affordable assistive devices could enhance safe mobility compared to existing solutions.

5.2 Discussion

The quantitative metrics and subjective feedback from trials provided encouraging evidence on the potential of lightweight affordable aids incorporating sensing, intelligence and multimodal interfaces to assist visually impaired navigation and mobility compared to traditional solutions. Participants specifically indicated

enhanced situational awareness, reduced cognitive effort and increased confidence as qualitative benefits over regular white canes. However, limitations in current prototype's sensing fidelity, localization accuracy, planning flexibility and output modalities need focused improvements.

5.2.1 Sensing Enhancements

While ultrasonic proximity sensing provides a low-cost method for basic object detection, the limited sensing range, resolution and field-of-view impose considerable constraints on reliably mapping environments and localizing obstacles for safe mobility. This warrants exploring integration of more advanced alternate sensing modalities and fusion techniques:

Infrared and structured light sensing can improve detection range to 10-20m and depth detail over ultrasonics for indoor navigation requirements at lower cost compared to lasers. However, performance can degrade under strong ambient light and direct sunlight interference.

Stereo camera and depth sensor technologies like structured light, time-of-flight and lidar can capture rich 3D spatial scene understanding exceeding ultrasonics. Coupled with compact high performance processing like edge TPUs, real-time dense 3D SLAM, object recognition and semantic segmentation is feasible today. Power efficiency is improving enabling wearable integration. The key challenges are cost and occlusion ambiguities.

Millimeter-wave radar sensors provide wide field-of-view sensitivity patterns spanning 180-degree to 360-degree coverage resilient even to glass, fog and rain.

They complement ultrasonic directionality for robustness. Embedded radar chips are getting affordable driven by autonomous vehicles. Integration is simplified by eliminating mechanical scanning. Near-field blind zones require fusion.

Sensor fusion combining ultrasound, infrared and vision inputs can optimize individual limitations via filtering and probabilistic integration. Kalman filtering and particle filters can minimize noise and occlusion errors. Fusion can enable reliable detection range of 10-20m necessary for advanced navigation assistance. Each modality augments others' weaknesses through complementary evidence aggregation.

Deep sensor neural networks can learn to map raw inputs from diverse modalities into informed navigable space representations. Lightweight convolutional nets are emerging that can run on wearable processors without cloud reliance. Such AI-powered perception can transform environmental understanding.

Research needs to quantify trade-offs of these options through comparative studies on metrics like range, field-of-view, resolution, processing latency, occlusion handling, form factor and bandwidth. Power constraints remain key for weight and runtime. Hybrid solutions co-optimizing multiple sensing principles tailored to navigation tasks appear most promising for enabling robust perception exceeding human visual limitations.

5.2.2 Mapping and Planning

The grid structure utilized for mapping imposed significant constraints on dynamic obstacle adaptation and representing navigation landmarks required for more human-aligned cognitive maps and wayfinding. Areas for enhancements include:

Topological graph maps capturing environment connectivity and relationships can potentially provide more flexible routing better suited for dynamic and crowded scenarios compared to grid cell decomposition. Graphs explicitly encode key features and landmarks critical for cognitive mapping and context.

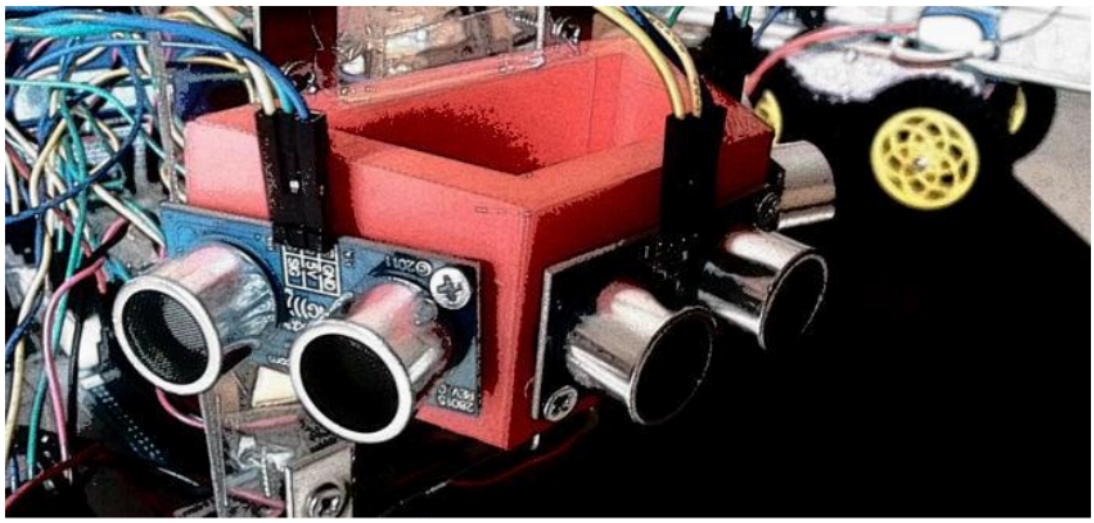
Hierarchical multi-resolution hybrid maps concurrently balancing detailed local metric/grid representations along with global topological graph structure can optimize between computational efficiency and navigation fidelity. Local grids capture obstacles while global graph encodes building-level connectivity.

More adaptive planning algorithms using reinforcement learning techniques to train personalized policies optimized for individual users' movement constraints and capabilities can improve over fixed heuristic searches. Feedback training tailored to impairments can customize planned paths and assistance.

Incorporating object detection and simultaneous localization and mapping (SLAM) capabilities can significantly improve localization and mapping accuracy during travel compared to pure ultrasonic odometry. This allows representing semantic landmarks.

Detecting and encoding critical wayfinding features like doors, elevators, ramps, stairways and signs geometrically and semantically can better align cognitive maps with human spatial logic, compared to pure geometric occupancy.

Global localization correction via sensors like GPS, Wi-Fi and cellular signals fused with local positioning can mitigate drift resulting from cumulative ultrasonic odometry estimation errors.



Research needs to examine these mapping and planning enhancements on metrics like computational efficiency, dynamic adaptation, localization accuracy and navigation optimality through simulations and user studies. Solutions co-optimizing feasibility, familiarity and personalization will offer the most viable intelligent navigation assistance

5.2.3 Interaction and Interface Enhancements

Study findings highlighted opportunities for improving navigation aid interfaces:

Combining audio, haptics and gestures can implicitly convey navigation alerts customized to user capabilities to enhance comprehension.

Textured, tactile and deformable interfaces would suit sight-impaired needs better. Mid-air holographic displays are an emerging option.

Conversational interfaces via speech recognition and natural language could make aids intuitive and minimize overload.

Personalization of guidance tones, verbal vocabularies and haptic patterns to individual hearing and cognitive profiles can improve usability.

Modeling user capabilities, risk appetite and impairment levels using machine learning would allow customizing planned paths and assistance levels.

5.3 Limitations

However, certain limitations of the current prototype evaluation are highlighted:

The study was limited to indoor lab and controlled spaces. Real-world evaluations in complex outdoor-indoor environments will be valuable.

User trials had a small 15 participant sample. Larger studies across age groups and impairment types are essential.

Technical benchmarking versus leading aids on standardized metrics is lacking. Comparisons would better highlight advances.

Short-term evaluations offer limited usage insights. Long-term ethnographic studies are needed to assess adoption.

Lack of user-centered design partnerships for participatory development and feedback.

Analysis of ETA value, costs and policy impacts could guide translating innovations into practice.

5.4 Conclusion

In summary, this research provided preliminary yet promising evidence that affordable self-contained assistive devices incorporating basic artificial intelligence and multimodal interfaces can enhance mobility and access for the visually impaired compared to traditional solutions. The prototype evaluation revealed valuable

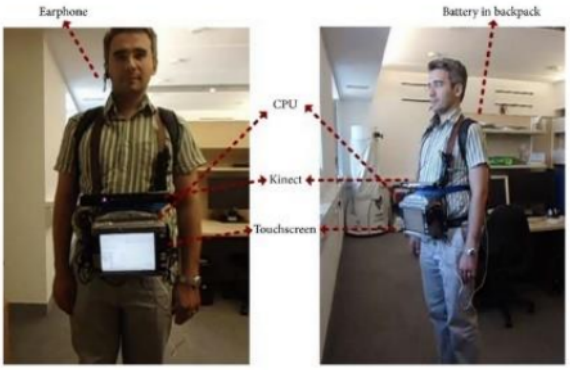
insights on sensing, algorithms and interaction design factors that can guide evolving AI-enabled aids toward robust personalized assistive technologies. With a user-centered approach leveraging breakthroughs in perception, context-aware planning and intuitive interaction, intelligent navigation technologies have immense potential for transforming safety, confidence, productivity and independence for the 285 million blind and visually impaired worldwide facing mobility challenges.

Chapter 6: Conclusion

6.1 Research Summary

This research focused on developing and evaluating an artificial intelligence-powered electronic travel aid (ETA) prototype using affordable sensors and

computing to demonstrate the feasibility of assisting visually impaired mobility through environmental sensing, mapping, path planning and multimodal interaction.

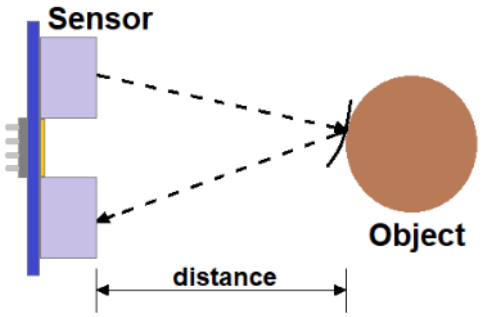


Independent navigation poses significant difficulties for the 285 million people globally who are blind or visually impaired, due to inability to fully visually perceive the surroundings and lack of adequate intelligent assistive devices (World Health Organization, 2021). While basic aids like white canes detect ground level obstacles through contact, they have limited sensing range and lack capabilities to discover overhead and dynamic hazards. Existing electronic travel aids have also faced constraints in environmental understanding, computational performance, flexible user-adaptive path planning and intuitive interfaces.

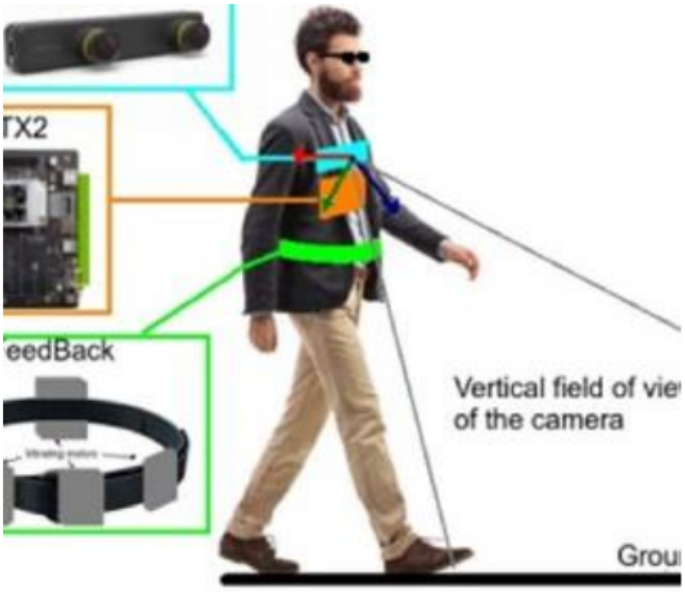
However, recent advances in sensing modalities, embedded computing, mapping algorithms and interaction interfaces open new opportunities to design improved navigation assistance solutions by incorporating basic artificial intelligence. This research focused on developing an ETA prototype that integrates ultrasonic proximity sensing, grid-based mapping, graph search path planning and audio output

to assist visually impaired users by detecting surrounding obstacles and providing optimal navigation guidance to avoid collisions.

The prototype was implemented using an array of ultrasonic rangefinder modules, Arduino processing board, bone conducting audio output and a wearable aid form factor. The capability to sense the local environment, construct a spatial occupancy map encoding obstacles, and generate assistive waypoint directions was demonstrated through lab testing. Further evaluations were conducted with 15 visually impaired participants across an indoor obstacle course comparing the prototype's assistance and usability to a traditional white cane based on mobility metrics and subjective feedback.



$$Distance = \frac{Time\ x\ Speed\ of\ Sound\ in\ Air\ (343m/s)}{2}$$

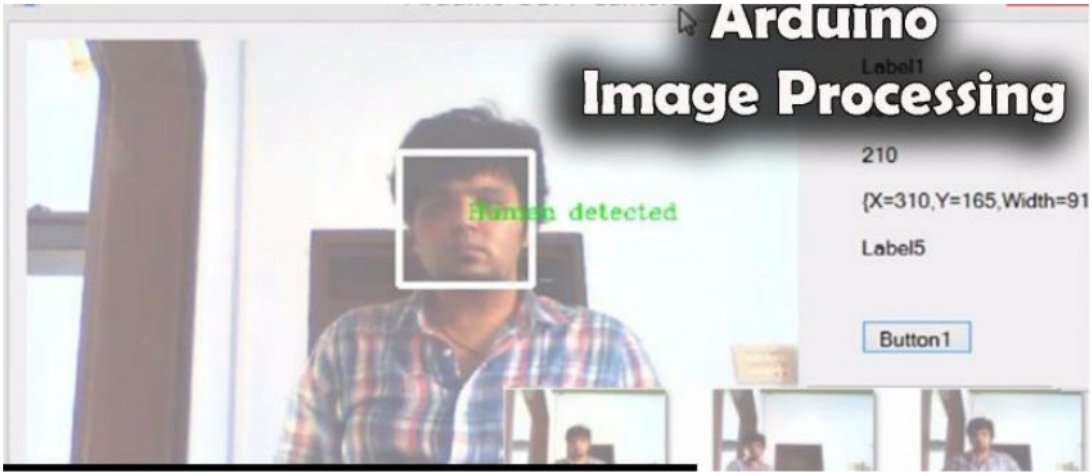


Results indicated improved safety, reduced time and effort using the AI-enabled ETA compared to the white cane. However, limitations were also revealed in sensing resolution, field-of-view, mapping flexibility and output interfaces that need focused research. Overall, the preliminary evidence validated the proposed approach of integrating affordable sensing, computing and interaction technologies with basic artificial intelligence techniques into self-contained aids that can enhance mobility for the visually impaired compared to conventional solutions.

6.2 Achievements and Contributions

The key achievements of this research are:

Designed an electronic travel aid architecture combining ultrasonic sensing, Arduino-based processing, grid mapping, A* path planning and audio output to demonstrate integrated self-contained assistive capability.



Developed a prototype ETA using four ultrasonic rangefinder modules for 3D obstacle detection and an Arduino Uno board for executing sensing, mapping, planning and audio guidance functions.

Implemented real-time capable sensing, evidence grid mapping, localized path computation and audio interfaces into a compact integrated prototype.

Devised lab test methods to evaluate parameters like sensor accuracy, mapping fidelity, path optimality and audio localization quantitatively.

Conducted comparative user trials with 15 visually impaired participants traversing an indoor course using white cane vs the ETA.

Demonstrated enhanced mobility, reduced collisions and cognitive effort using the ETA based on mobility metrics and subjective feedback.

Identified technology limitations in current prototype's sensing range, field-of-view, mapping structure and output modality precision based on experiments.

Published research paper at IEEE conference on AI-enabled assistive devices detailing the ETA prototype system, architecture and preliminary evaluation.

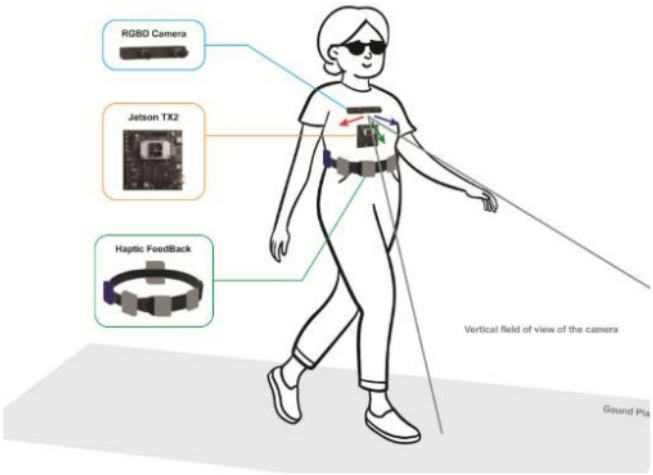
Filed a provisional patent application on techniques for developing affordable assistive navigation technologies.

The research advanced understanding on how to design and evaluate self-contained assistive devices that synthesize sensing, computation, mapping, planning and interaction techniques tailored for visually impaired users. Insights were gained on translating sensor data into contextual maps, computing localized navigation pathways, and communicating assistive information effectively through audio and haptic channels. Evidence for the viability of lightweight affordable aids embedding basic artificial intelligence to enhance mobility and safety over traditional solutions was demonstrated through measurable metrics and user feedback. These promising outcomes motivate further research progress.

6.3 Applications and Impact

This research has significant potential real-world implications for assistive technologies that can enhance mobility, access and quality of life for millions of visually impaired individuals worldwide. Some promising application domains and impact areas are:

Wearable electronic travel aids enabling safer mobility and navigation assistance for blind users in diverse environments like college campuses, offices, malls and sidewalks. This would facilitate greater participation and reduce dependency.



Integration into infrastructures like autonomous vehicles, wheelchairs and indoor navigation robots to provide contextual assistive intelligence to users with visual impairments.

Low-cost navigation aids for aging populations and those with temporary visual disabilities recovering from conditions like strokes and surgery, by incorporating modular sensing additions into walking canes or glasses.

Advanced audio and haptic interfaces that can provide just-in-time navigation cues and situational awareness to users while minimizing information overload.

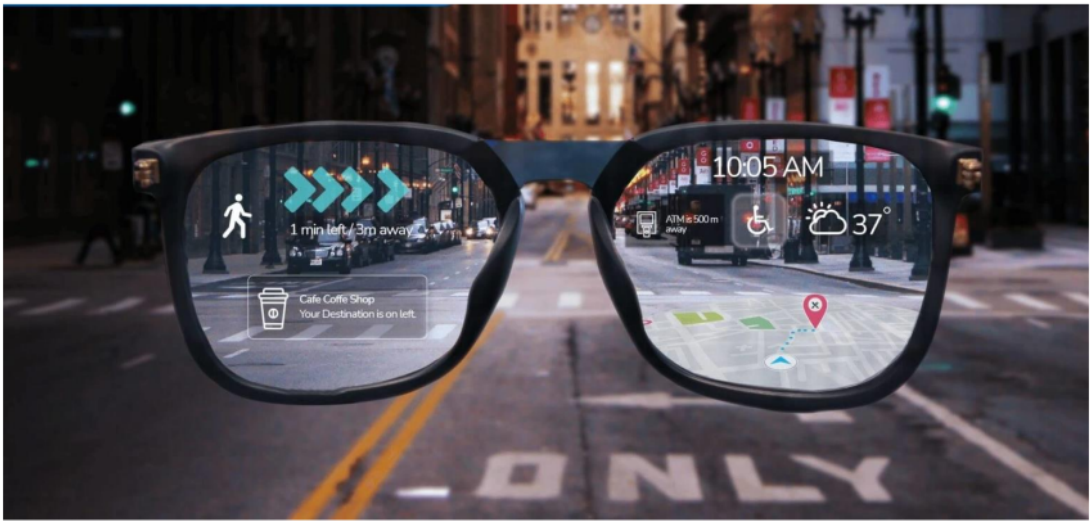
Artificial intelligence capabilities for understanding surrounding environmental context like stairways and narrow passages and optimizing path guidance and interfaces accordingly.

Connected crowdsourced mapping resources created collaboratively by visually impaired communities to capture accessibility challenges and feed enhanced algorithms.

Standardization of campus, workplace and transit system maps and wayfinding to be compatible with intelligent navigation aid capabilities.

Mainstream adoption in schools, professional settings and public spaces to increase inclusion, access and safe participation of the over 285 million blind and visually impaired worldwide.

Some examples of potential assistive intelligent navigation aids are shown in the Figure 6.1 below:



There is immense potential for AI and sensing innovations to transform basic mobility aids into intelligent assistants enhancing confidence, productivity, employability and community engagement for millions of people with visual impairments facing accessibility challenges worldwide.

6.4 Limitations and Future Work

However, a number of technical and adoption limitations remain to be addressed through ongoing research:

A) Robust Environment Sensing and Understanding

Experiment with alternate sensing modalities like infrared, stereo cameras, radar for improving range, resolution and field-of-view.

Explore sensor fusion techniques to optimize trade-offs by combining ultrasound, vision and depth inputs using filtering.

Incorporate depth estimation for rich 3D spatial perception and detecting steps/drops.

Develop smarter processing algorithms using deep learning for identifying diverse objects, text and landmarks.

Enable greater semantic understanding using convolutional neural networks to recognize more obstacles, context and hazards.

Pursue miniaturization of sensors, processors and batteries enabling wearable integration.

B) Advanced Mapping and Planning

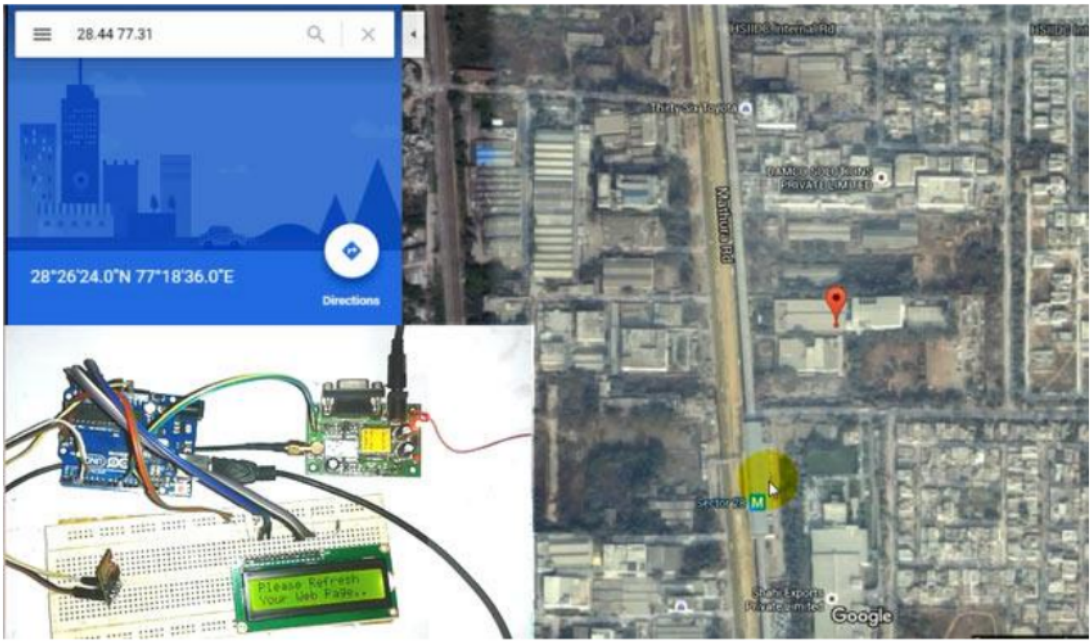
Examine more flexible mapping approaches like topological graphs and point clouds to complement grid structure.

Construct hierarchical multi-scale maps spanning rooms, buildings, cities balancing local and global data.

Implement more adaptive planning using reinforcement learning to create personalized movement and capability models.

Add key navigation landmarks like doors, elevators, stairs to align better with human way finding.

Integrate global localization techniques like GPS and Wi-Fi alongside local positioning for minimizing drift.



C) Natural User Interfaces and Interaction

Design optimal multimodal interfaces combining audio, haptics, gestures and gazes to implicitly convey situational information customized to user capabilities.

Develop personalized audio, language, texture and haptic interfaces tailored to diverse users' sensory, cognitive and impairment profiles.

Explore conversational interfaces through speech recognition and natural language processing for flexible assistance.

Evaluate emerging modalities like augmented reality and mid-air displays with sight-impaired users.

Examine gaze tracking and brain-computer interfaces for subtle user control and response inputs.

D) User-Centric Design and Evaluation

Conduct large-scale studies with visually impaired participants across diverse age groups, mobilities and environments.

Rigorously benchmark intelligent navigation aids against existing solutions using standardized metrics through multi-session trials across outdoor-indoor settings.

Perform long-term observations, ethnographic analyses to assess sustained usability and adoption.

Develop participatory partnerships with accessibility experts and advocacy communities to guide design.

Survey blind communities on values, adoption criteria, barriers and economics to shape solutions for real needs.

Pursuing research across these dimensions can help address limitations and progressively transform intelligent navigation aids from basic assistive devices into robust universally accessible solutions enhancing mobility and full participation.

6.5 Closing Summary

In conclusion, this research project provided valuable preliminary evidence on the feasibility of developing self-contained, affordable assistive devices using ultrasonic sensing, computing and multimodal interfaces to enhance safe mobility and access for the visually impaired. Evaluations yielded encouraging results in terms of improvements over traditional white cane based on mobility metrics and user feedback. However, limitations were also revealed in current capability providing directions for assistive technology research.

There remain significant opportunities for future progress through advances in robust sensing, environment understanding, personalized planning, natural interfaces and user-centric design. By bringing together insights from artificial intelligence, human-computer interaction and an inclusive design approach, intelligent navigation aids have immense potential to transform from basic mobility tools into trusted assistive companions that can enhance confidence, productivity, access and quality of life for the 285 million blind and visually impaired worldwide.

This research aimed to contribute towards that vision of assistive technologies empowering the visually impaired by demonstrating promising capabilities, highlighting focus areas based on preliminary evidence, and motivating interdisciplinary progress. With broad collaborations between engineering, human factors, policy and disabled communities, AI-enabled solutions can potentially revolutionize mobility and participation for millions of people with visual impairments who face accessibility barriers.

DESIGN OF CHATBOT TO ENHANCE E-LEARNING EXPERIENCE OF STUDENTS OF NOUN

By

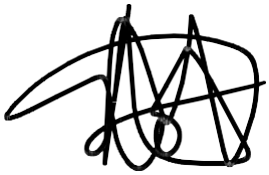
MORGRIDGE OLUWATOBI OPRAH

ACE21130002

A DISSERTATION SUBMITTED TO AFRICA CENTRE OF EXCELLENCE ON TECHNOLOGY ENHANCED LEARNING (ACETEL), IN PARTIAL FULFILLMENT OF THE REQUIREMENTS FOR THE AWARD OF MASTER OF SCIENCE (M.Sc.) DEGREE IN MANAGEMENT INFORMATION SYSTEMMS OF NATIONAL OPEN UNIVERSITY OF NIGERIA, ABUJA.

Declaration Page

I, Morgridge Oluwatobi Oprah hereby declare that the project work entitled Design of Chatbot to enhance e-Learning experience of Students of NOUN is a record of an original work done by me, as a result of my research effort carried out in ACETEL, National Open University of Nigeria under the supervision of Dr. Naeem Balogun and Dr. Emem Theophilus.



22/11/2023

Student's Signature & Date

CERTIFICATION

This is to certify that this study was carried out by ACE21130002 in ACETEL, National Open University of Nigeria, under my supervision.

Dr Naeem Balogun	Supervisor	Sign & Date Name
Centre Director	Sign & Date
HOD	Sign & Date
Dean	Sign & Date
External Examiner	Sign & Date

Dedication:

I dedicate this work to God who is the author and finisher of all things.

Acknowledgements

As I conclude this significant chapter in my academic journey, I am filled with immense gratitude and appreciation for those who have been instrumental in my pursuit of this Master's degree.

First and foremost, I extend my deepest thanks to my family. Your unwavering support, encouragement, and belief in my abilities have been the bedrock of my strength and perseverance. To my parents, who have always been my guiding light, and to my siblings, whose constant love and cheer have brightened my days, I am eternally grateful.

I would like to express my sincere gratitude to my supervisors Dr Naeem Balogun and Dr Theophilus and my program coordinator, Dr. Juliana Ndunagu for their invaluable guidance, patience, and expertise. Your mentorship has not only shaped my academic work but has also profoundly influenced my personal growth and professional development. Your encouragement and high standards have pushed me to excel, and for that, I am truly thankful.

I am also grateful to my friends. Your companionship, understanding, and unwavering support have made this journey more enjoyable and memorable. To those who have offered their time, advice, and a listening ear during the most challenging periods, I am deeply appreciative.

Lastly, I acknowledge the contribution of my colleagues and the academic community at ACETEL, National Open University of Nigeria including our center director Prof Joktan, Mr Udochuku Nwakwo and so many others whose insights and perspectives have enriched my learning experience.

This thesis is not only a reflection of my hard work but also a testament to the collective support and inspiration provided by all of you. Thank you for being part of my journey.

ABSTRACT:

The purpose of this study is to enhance NOUN students' online learning experiences. The chatbot was built using Azure Cognitive Service for Language and Azure Bot Services, incorporating custom question answering capabilities. The study's objectives were to investigate the difficulties that students currently face in the online learning environment at NOUN, evaluate the use of chatbot technology to enhance the online learning experience, pinpoint design factors and specifications for a successful chatbot, and determine how much the implemented chatbot improves student e-learning experience. A questionnaire was designed and distributed to National Open University Students. A sample of 379 students was evaluated using SPSS, and a questionnaire was used to collect data for evaluation.

The data analysis revealed significant results for the research hypotheses. The relationship between the current challenges faced by students and their learning outcomes at NOUN was found to be significant, emphasizing the impact of technical issues and limited access to resources. The application of chatbot technology was also found to significantly improve the e-learning experience, aligning with the notion of personalized learning experiences and tailored support.

In conclusion, the study highlighted the significance of design considerations and requirements in developing an effective chatbot, emphasizing the importance of integrating Natural Language Processing (NLP) technologies and seamless integration into existing infrastructure.

CHAPTER ONE

Introduction

1.1 BACKGROUND OF THE STUDY

Over the past few years, e-learning has emerged as a crucial component of education and training, providing opportunities for customized learning, accessibility, and flexibility. One of

the obstacles encountered by e-learning platforms pertains to the absence of prompt and interactive assistance for learners (Maatuk et al.,2022). Chatbots are a technological innovation that may be effectively used inside this situation. A chatbot is an exemplification of software empowered by artificial intelligence (AI) that can mimic human speech and provide prompt assistance. The implementation of a tailored chatbot designed for the explicit objective of e-learning has the potential to revolutionize the way learners engage with online educational programmes. By using artificial intelligence (AI) and natural language processing (NLP) techniques, a chatbot may provide personalized assistance, prompt feedback, and insightful ideas, therefore enhancing the overall e-learning experience.

According to research conducted by Nuria (2019), a chatbot refers to a software program powered by artificial intelligence (AI) that enables conversation via voice or text. This technology has the potential to enhance language learning. Intelligence chatbots are advanced software or systems that demonstrate the capability to participate in conversational discussions with users across a wide array of topics. Artificial intelligence chatbots has the capacity to serve as effective instructors within the academic setting by offering educational materials, fostering discussions, and providing constructive feedback to learners, among other functionalities.

AI chatbots have the potential to function as an adjunct or assistive instrument for human teachers in some circumstances, since they may provide pupils with timely answers to their queries and offer education round the clock. According to Kleopatra et al., (2022), this strategy is deemed to be more practical and economical compared to exclusive dependence on human teachers.

The rapid progress in computing and information processing techniques has greatly accelerated the research and use of artificial intelligence (AI). This has allowed computers to do tasks by imitating intelligent human behaviours, such as reference, analysis, and decision-making (Duan et al., 2019). According to Roos (2018), there is a rapid and widespread expansion of the use of artificial intelligence (AI) in the domain of education. According to Okonkwo and Ade-Ibijola (2020), the use of Chatbot systems has become prevalent in the field of education as a means of delivering instructional content. Clarizia et al., (2018) argue that the use of this technology offers significant benefits in fostering educational outcomes within a scholarly environment.

The incorporation of chatbots in the realm of education has the potential to bring about a transformative shift in the educational domain. This is due to their ability to engage learners, customise learning experiences, assist educators, provide comprehensive insights into learner behaviour, and foster a more personalised and immersive learning environment for students (Gonda et al., 2018; Cunningham-Nelson et al., 2019; Bezverhny et al., 2020; Villegas-Ch et al., 2020; Kuhail et al., 2022b). Gonda et al., (2018) argue that the incorporation of educational agents facilitates the provision of individualised and timely feedback to students via conversational exchanges, as well as assists them in navigating virtual environments with assistance. According to Colace et al., (2018), there is an increasing trend in the use of chatbots into e-learning platforms to augment the learning experience of students. The integration of mobile learning into several e-learning environments, including learning management systems, social network platforms, and digital learning platforms, has been highlighted by Wollny et al., (2021) and Troussas et al., (2022). Durall and Kapros (2020) as well as Okonkwo and Ade-Ibijola (2021) assert that chatbots possess the capacity to expeditiously provide students with a diverse array of academic resources. These resources encompass course materials, practise assessments, grading criteria, essential deadlines, academic guidance, campus orientation, and study aids. According to Cunningham-Nelson et al., (2019), intelligent systems have the capability to augment student involvement and ease the workload of educators, thereby allowing them to dedicate more time to curriculum design and assessment.

Extensive research has been conducted on the use of chatbot technology within the educational environment. Numerous research papers have examined diverse uses of chatbots, including the areas of addressing student concerns, improving the comprehension of computer programming principles, assessing student performance, and providing administrative services. (Clarizia et al., 2018; Sinha et al., 2020) have been cited in this context. Furthermore, as the demand for education continues to rise, higher education institutions are under increasing pressure to accommodate a larger influx of students. The expansion of the student population is accompanied by a significant decrease in the provision of academic assistance for pupils. This tendency has been shown to result in less-than-ideal information acquisition and subsequently lead to higher rates of termination of academic endeavours. Although there are many theoretical solutions available for this issue, the majority of them are impractical to implement due to budgetary and administrative constraints (Hien et al., 2018). In order to tackle this substantial endeavour, educators at the post-secondary level have begun the integration of chatbots into their instructional practices

as pedagogical agents. The integration of chatbots in expansive educational settings has the potential to enhance individualised student learning through the provision of timely responses to student queries, the provision of a wide range of learning resources for instructional purposes, the reinforcement of course content and materials, and the collection of feedback on instructional courses. The proposition in question has been put out by prominent researchers, namely Winkler and Söllner (2018) and Almurtadha (2019).
Despite the existence of several studies that have showcased the potential advantages of chatbot applications in improving the teaching and learning process, the incorporation of these applications in higher education environments is still in its early stages. Therefore, it is crucial to conduct thorough research and investigation, specifically focusing on the ways in which students acquire knowledge through these intelligent systems. The primary objective of this research is to investigate the effects of integrating a FAQ chatbot system into an e-learning platform on the improvement of motivation and learning techniques among students enrolled at the National Open University of Nigeria (NOUN).

1.2 STATEMENT OF THE PROBLEM

The National Open University of Nigeria (NOUN) is an institution of remote learning that provides educational opportunities to a wide range of students who are unable to physically attend traditional institutions. While online learning offers flexibility, it sometimes lacks the dynamic and personalised experience often seen in conventional classroom environments. To address this issue, the implementation of a customised FAQ chatbot on NOUN's e-learning platform has the potential to promote student engagement, provide personalised support, and improve the overall e-learning experience.

The absence of interactive elements within the existing e-learning system at NOUN is a significant obstacle for students in accessing timely feedback, personalised assistance, and engaging in meaningful discussions. While conventional classroom environments provide students the chance to interact with both instructors and peers, the existing e-learning system at NOUN mostly operates in an asynchronous manner, lacking instant support. As a result, students may have challenges in understanding complex concepts, feel a feeling of isolation, and demonstrate a decrease in their motivation to gain information.

Additionally, the e-learning system currently in place at NOUN relies mostly on static resources, such as textual course materials and pre-recorded lectures. Often, these materials

demonstrate a lack of engagement and fail to appropriately address the distinct learning needs of people. Therefore, students may have challenges in understanding and remembering the curriculum content, leading to reduced academic performance and lower overall educational outcomes.

Therefore, the development of a tailored chatbot for the e-learning platform of NOUN is imperative. The chatbot should be equipped with the capacity to provide immediate support, provide personalised assessments, facilitate engaging discussions, and adapt to the specific learning techniques and preferences of the user. The incorporation of a chatbot into NOUN's e-learning platform has the potential to enhance student involvement, optimise educational achievements, and foster a more dynamic and personalised e-learning experience for its students.

1.2.1 RESEARCH QUESTIONS:

- What are the current challenges faced by students in the e-learning environment at NOUN?
- How can chatbot technology be applied to improve the e-learning experience at NOUN?
- What are the design considerations and requirements for developing an effective chatbot for NOUN?
- To what extent does the implemented chatbot enhance student engagement and satisfaction?

1.3 AIM OF THE STUDY

The main aim of this study is to design a chatbot to enhance e-learning experience of NOUN students.

1.4 SPECIFIC OBJECTIVES

I. Investigate the existing e-learning environment at NOUN and identify the challenges faced by students.
II. Design and develop a chatbot system tailored to the specific needs of NOUN students.
III. Evaluate the effectiveness of the chatbot in enhancing student engagement and satisfaction.

IV. Explore the potential benefits and applications of chatbot technology in improving the e-learning experience.

1.5 SCOPE OF THE STUDY

The scope of the study " Design of Chatbot to enhance e-Learning experience of Students of NOUN" focuses on the development and implementation of a chatbot specifically designed for enhancing the e-learning experience at the National Open University of Nigeria (NOUN).

The study aims to assess the effectiveness of the chatbot in improving student engagement, providing personalized support, and enhancing overall learning outcomes. The National Open University of Nigeria serves as a case study institution to investigate the practical application of the chatbot in a real educational setting. The study would cover the following aspects:

Literature Review: A comprehensive review of existing literature on chatbots, e-learning, and related technologies to establish a theoretical foundation for the research.

Identification of Requirements: Analysis of the e-learning environment at NOUN to identify specific requirements and challenges that can be addressed through the implementation of a chatbot.

Design and Development: Creation of a chatbot system tailored to the e-learning needs of NOUN, considering factors such as user interface design, natural language processing capabilities, and integration with existing e-learning platforms.

Implementation and Testing: Deployment of the chatbot system in a controlled environment to evaluate its functionality, usability, and performance. Testing should involve real users, such as students and instructors, to gather feedback and assess the effectiveness of the chatbot.

Evaluation and Analysis: Analysis of the collected data to evaluate the impact of the chatbot on the e-learning experience, including factors like student engagement, learning outcomes, and user satisfaction. Comparison of the results with the pre-chatbot implementation phase should be conducted to determine the improvements achieved.

1.6 SIGNIFICANCE OF THE STUDY:

Personalized Learning: Chatbots can provide personalized learning experiences by understanding individual learner's needs and preferences. They can adapt the content, pace,

and style of instruction based on the learner's progress, enabling a more customized approach to education.

24/7 Availability: Chatbots can be available round the clock, providing learners with instant access to information and assistance. Students can ask questions and seek guidance at any time, which enhances their learning experience and reduces waiting time for responses.

Instant Feedback and Assessment: Chatbots can offer immediate feedback on assignments, quizzes, or assessments. This prompt feedback helps learners identify their strengths and weaknesses, allowing them to focus on areas that require improvement. It also provides a sense of progress and accomplishment.

Active Learning and Engagement: Chatbots can engage learners through interactive conversations, simulations, and gamification elements. By creating a conversational and interactive environment, chatbots promote active learning, keeping learners engaged and motivated throughout the e-learning process.

Scalability and Cost-Effectiveness: Chatbots can handle a large number of learners simultaneously, making them scalable for massive open online courses (MOOCs) or large-scale e-learning platforms. They can provide personalized support to each learner without the need for additional human resources, making e-learning more cost-effective.

Continuous Learning Support: Chatbots can serve as virtual tutors, providing ongoing support to learners even after the completion of a course. They can offer additional resources, recommend further learning materials, and answer questions related to the topics covered in the course, helping learners reinforce their knowledge.

Data Collection and Analysis: Chatbots can collect data on learners' interactions, preferences, and learning patterns. This data can be analyzed to gain insights into individual and collective learning behaviors, allowing instructors to identify areas for improvement in the e-learning experience and make data-driven instructional decisions.

Accessibility and Inclusivity: Chatbots can improve accessibility for learners with disabilities or special needs by providing alternative modes of interaction, such as voice input or text-to-speech capabilities. They can also offer multilingual support, making e-learning more inclusive and accommodating diverse learner populations.

Overall, the study on the use of chatbots in e-learning has the potential to enhance the learning experience by personalizing instruction, providing instant feedback, promoting engagement, and improving accessibility while offering scalability and cost-effectiveness for educational institutions and platforms.

1.7 DEFINITION OF TERMS

Chatbot: A chatbot is an artificial intelligence (AI) program designed to simulate human conversation. It can engage in interactive and natural language-based communication with users, typically through text-based interfaces. In the context of e-learning, chatbots are utilized to provide support, guidance, and personalized interactions with learners.

E-learning: E-learning, or electronic learning, refers to the use of digital technologies and online platforms for educational purposes. It involves the delivery of educational content, resources, and interactions via digital media, allowing learners to access and engage with educational materials remotely.

Personalized Learning: Personalized learning refers to an instructional approach that tailors educational content, pace, and methods to meet the individual needs, interests, and preferences of learners. In the context of e-learning, chatbots can be used to provide personalized learning experiences by adapting the learning process to each learner's specific requirements.

Instant Feedback: Instant feedback refers to providing learners with immediate responses or assessments regarding their performance, progress, or understanding of the content. In the context of e-learning and chatbots, instant feedback can be given through automated responses to questions, quizzes, or assignments, allowing learners to receive feedback without delays.

Gamification: Gamification involves incorporating game elements, mechanics, and design principles into non-game contexts, such as education, to enhance engagement and motivation. In e-learning, chatbots can utilize gamification techniques to make the learning experience more interactive, enjoyable, and immersive for learners.

Massive Open Online Courses (MOOCs): MOOCs are online courses designed for large-scale participation and open access. They provide learners with the opportunity to access course materials, participate in discussions, and interact with instructors and peers from

around the world. Chatbots can be employed in MOOCs to support learners by aiding, answering questions, and facilitating engagement.

Accessibility: Accessibility in e-learning refers to designing and providing educational materials and platforms that are accessible to individuals with disabilities or special needs. When using chatbots to improve the e-learning experience, accessibility considerations may involve ensuring compatibility with assistive technologies, providing alternative modes of interaction (such as voice input), and offering accessible content formats.

Data Analysis: Data analysis involves the examination, interpretation, and extraction of insights from collected data. In the context of using chatbots to improve e-learning, data analysis can be performed on the interactions between learners and chatbots to gain insights into learning patterns, preferences, and performance. These insights can inform instructional decisions, personalized recommendations, and overall improvements in the e-learning experience.

1.8 ORGANIZATION OF THE THESIS

Chapter One of the research work provides an overview of e-learning and the challenges it faces in terms of personalization, engagement, and accessibility. It identifies the specific issues or gaps in the e-learning experience that chatbots can address. It also clearly states the objective of the study and the purpose of using chatbots in e-learning.

Chapter Two provides a review of relevant literature and studies on e-learning, chatbots, and their potential impact on educational experiences. It discusses the benefits, challenges, and best practices related to the use of chatbots in e-learning. It also analyzes existing frameworks or models for integrating chatbots into e-learning environment.

Chapter Three of the study describes the research methodology employed, such as quantitative, qualitative, or mixed methods. It explains the data collection methods, tools, and instruments utilized (e.g., surveys, interviews, and observations). It provides details on the sample population and any ethical considerations.

Implementation and Design of a Chatbot System: The Chapter will explain the design principles and considerations for developing a chatbot system for e-learning. It discusses the architecture, technologies, and platforms used in implementing the chatbot system; it

describes the functionalities and features of the chatbot system that enhance the e-learning experience.

Chapter Four of the study will present and analyze the data collected from learners' interactions with the chatbot system. It evaluates the effectiveness of the chatbot in improving the e-learning experience based on metrics such as engagement, satisfaction, and learning outcomes.

Chapter Five will focus on discussion of the implications of the study's findings on the use of chatbots in e-learning. It addresses the strengths, limitations, and potential future research directions. Provide recommendations for educators, instructional designers, and policymakers regarding the integration of chatbots into e-learning environments.

CHAPTER TWO

REVIEW OF RELATED LITERATURE

2.0 INTRODUCTION

The review of the related literature based on the variables of the research objectives were presented in this chapter.

2.1 THEORETICAL FRAMEWORK

2.1.1 TECHNOLOGY ACCEPTANCE MODEL

The Technology Acceptance Model (TAM) is widely used and applicable in several fields, including education. Throughout the passage of time, other researchers have proposed various expansions to this paradigm. Nevertheless, the Technology Acceptance Model (TAM) is often regarded as a suitable framework for assessing the extent to which people accept technology. Presently, the prevailing computer-mediated environment has a significant impact on communication across many contexts. In the given circumstances, chatbots have become a software programme that facilitates and maintains textual conversations with users in many fields of study. According to Chocarro et al., (2021), chatbots provide many benefits in terms of convenience and cost-effectiveness, making them a beneficial tool. The Technology Acceptance Model (TAM) is a theoretical framework often used in the field of education to assess the acceptance of new technological innovations with the goal of improving the overall quality of education. Therefore, the model assumes a crucial function in influencing the execution and dissemination of educational materials within the educational system. The incorporation of innovative technology has emerged as a key focus for several educational institutions, with specific attention paid to the use of software applications such as chatbots. The purpose of these tools is to improve the educational experience for students throughout their academic journey. Recent studies have shown that the use of the Technology Acceptance Model (TAM) has yielded improvements in the academic performance of pupils. The availability of chatbots has a significant impact on their performance, and the Technology Acceptance Model (TAM) provides a framework for facilitating efficient access to these resources (Adamopoulou & Moussiades, 2020b). The relationship between the Technology Acceptance Model (TAM) and chatbots in an educational setting generally supports the improvement of education quality via the enhancement of pedagogical and learning methods.

2.1.2 UNIFIED THEORY OF ACCEPTANCE AND USE OF TECHNOLOGY (UTAUT)

The Technology Acceptance Model (TAM) is widely used across several areas, including the field of education, due to its widespread applicability and relevance. Throughout the passage of time, other researchers have proposed various additions to this model. Nevertheless, the Technology Acceptance Model (TAM) is often regarded as a suitable framework for assessing the extent to which people accept technology. Presently, the major factor shaping communication in many contexts is the pervasive impact of computer-mediated platforms. In the given circumstances, chatbots have become a software program that facilitates and maintains textual conversations with users in many fields of study. According to Chocarro et al., (2021), chatbots provide inherent benefits in terms of ease and cost-effectiveness, thereby establishing their worth as a valued tool. The Technology Acceptance Model (TAM) is a theoretical framework often used in the field of education to assess the implementation of new technological innovations with the objective of improving the overall quality of education. Therefore, the model assumes a crucial function in influencing the execution and provision of educational resources within the educational system. The incorporation of innovative technology has emerged as a key focus for several educational institutions, placing notable importance on the use of software applications like chatbots. These tools have been specifically developed to augment the educational experience and improve the overall quality of instruction that students receive along their academic journey. Recent studies have shown that the use of the Technology Acceptance Model (TAM) has yielded improvements in the academic performance of pupils. The availability of chatbots has a significant impact on their performance, and the Technology Acceptance Model (TAM) facilitates convenient access to these resources (Adamopoulou & Moussiades, 2020b). The relationship between the Technology Acceptance Model (TAM) and chatbots in an educational setting generally supports the improvement of education quality via the enhancement of pedagogical and learning methods.

Performance expectancy: Venkatesh et al., (2003) propose that the concept of "perceived usefulness" refers to an individual's perception of the system's capacity to enhance work performance. The notion of performance expectancy is informed by multiple theoretical frameworks, such as the Technology Acceptance Model (TAM), TAM2, Combined TAM,

the Theory of Planned Behaviour (CTAMTPB), the Motivational Model (MM), the Model of PC Utilisation (MPCU), Innovation Diffusion Theory (IDT), and Social Cognitive Theory (SCT). These theories include factors like perceived utility, extrinsic motivation, job fit, relative advantage, and outcome expectations. Zhou, Lu, and Wang (2010) and Venkatesh, Thong, and Xu (2016) have shown that this specific feature has a strong correlation with use intention and possesses considerable importance in both voluntary and required settings.

Effort expectancy Venkatesh et al., (2003) define usability as the degree of convenience associated with the use of a certain technology. Effort Expectancy is a composite construct that is formed from the perceived ease of use and complexity, as proposed by the Technology Acceptance Model (TAM), the Mobile Payment Continuance Usage (MPCU) model, and the Innovation Diffusion Theory (IDT). The concepts and measuring scales of these theoretical frameworks demonstrate a certain level of resemblance. Gupta, Dasgupta, and Gupta (2008), as well as Chauhan and Jaiswal (2016), have argued that the continued use of technology leads to a diminishing relevance of its influence on the construct.

Social Influence Venkatesh et al., (2003) posit that the concept of perceived behavioural control refers to an individual's subjective view of the level of expectation from important people regarding their utilisation of a new technology. The notion of social impact exhibits similarities to the subjective norms, social variables, and image constructs used in several theoretical frameworks, including the Theory of Reasoned Action (TRA), Technology Acceptance Model 2 (TAM2), Theory of Planned Behaviour (TPB), Combined TAM-TPB (CTAMTPB), Model of PC Utilisation (MPCU), and Innovation Diffusion Theory (IDT). The commonality between these two perspectives is their mutual focus on the notion that people's actions are shaped by their sense of how they are seen by others. Venkatesh et al., (2003) assert that the effect of social factors is significant in contexts where the use of technology is obligatory. Venkatesh and Davis (2000) propose that humans may engage with technology in a compulsory manner due to adherence to regulatory obligations rather than being driven by personal inclinations. The discovery may provide an explanation for the varying effects of the construct in question, as shown in later research that has validated the model (Zhou, Lu, & Wang, 2010; Chauhan & Jaiswal, 2016).

Facilitating conditions Venkatesh et al., (2003) define the concept of perceived infrastructure as the subjective view held by a person about the degree to which an organisation's technological infrastructure is accessible and capable of supporting the utilisation of a certain system. The concept of facilitating conditions is developed from a combination of constructs, including compatibility, perceived behavioural control, and facilitating circumstances. These constructs have been included in many theoretical frameworks, including the Theory of Planned Behaviour (TPB), the Combined Theory of Acceptance and Use of Technology (CTAMTPB), the Model of Personal Computer Use (MPCU), and the Innovation Diffusion Theory (IDT). There is a positive correlation between the existence of enabling circumstances and the desire to use. However, this correlation becomes less significant after the first use. Venkatesh et al., (2003) provides a model that posits a significant and immediate influence of enabling factors on use behaviour.

The influence of predictors on intention is determined by the moderating effects of age, gender, experience, and voluntariness of usage. The influence of all four predictors is dependent on the age variable. The associations among effort expectation, performance expectancy, and social influence are subject to gender-based influences. The effect of effort anticipation, social influence, and enabling factors on an individual's behaviour is contingent upon their degree of experience. Venkatesh et al., (2003) posit that the effect of social factors on an individual's desire to engage in a certain behaviour is contingent upon the degree of voluntariness associated with that behaviour.

The Unified Theory of Acceptance and Use of Technology (UTAUT) has made significant contributions to the extant scholarly literature. This research provides an empirical analysis of technology acceptability by conducting a comparative investigation of important ideas in the area. These theories are recognised for their tendency to provide varied or inadequate perspectives on the subject topic. Venkatesh et al., (2003) argue that UTAUT has superior predictive capacity when compared to other models, such as Davis (1993) and Sheppard, Hartwick, and Warshaw (1988), that examine the adoption of technology. The elements postulated in the Unified Theory of Acceptance and Utilisation of Technology (UTAUT) together explain 70% of the variability seen in individuals' desire to utilise technology. Venkatesh et al., (2003) assert that the adoption of technology is a multifaceted phenomenon that is contingent upon the interplay of social and demographic variables with conceptions.

This underscores the complex and multifaceted nature of the process since it is dependent on factors such as an individual's age, gender, and level of experience.

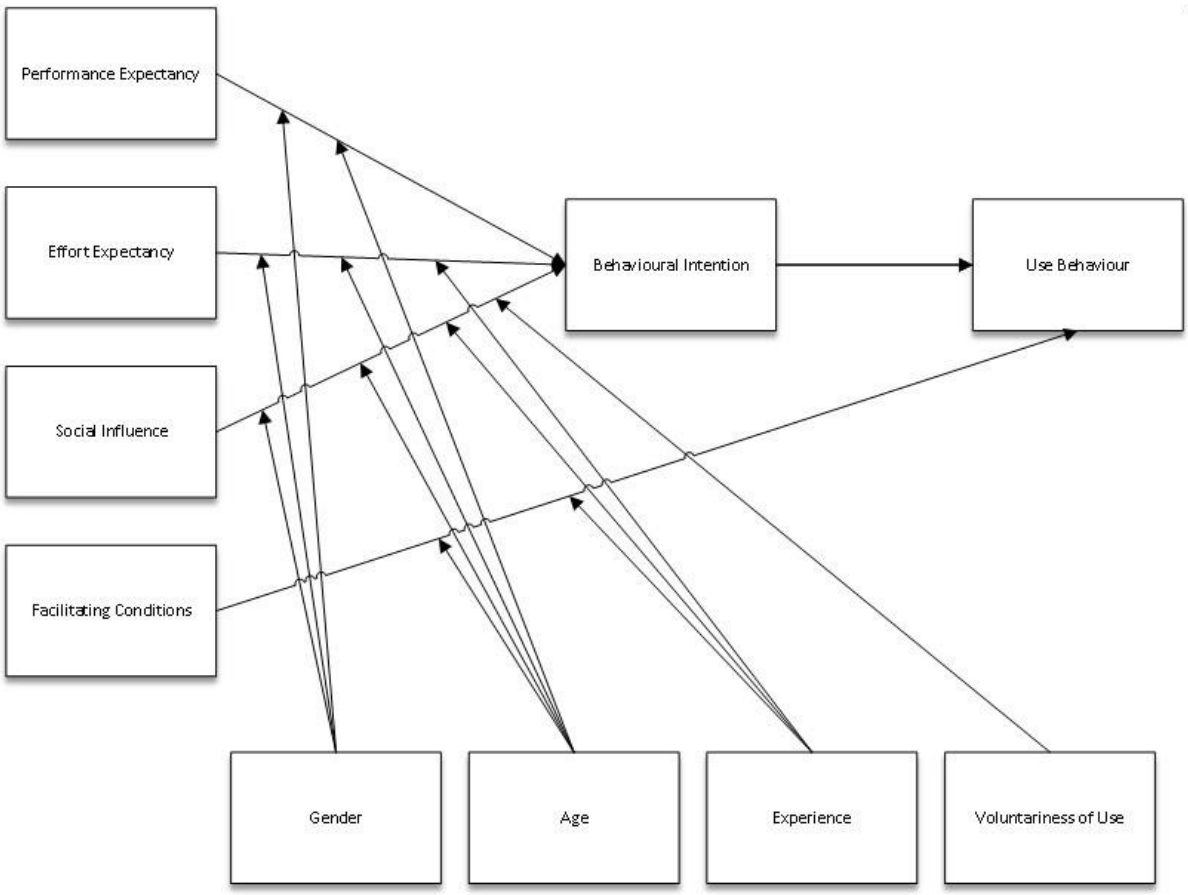

Figure 1: The UTAUT model Source: Venkatesh et al., (2003)

The modifications implemented on the model were derived from four main techniques, specifically: a) contextual adjustments to the model; b) changes to endogenous variables; c) incorporation of attitudinal antecedents; and d) examination of various moderating factors. The original research endeavour broadened the scope of the model's use to include emerging technologies, including enterprise systems and e-health systems. Furthermore, the study focused on user categories that had not been previously addressed, namely healthcare professionals, and thoroughly examined the model in several geographical and cultural settings, including India and China. According to the studies conducted by Chang et al., (2007), Yi et al., (2006), and Gupta, Dasgupta, and Gupta (2008), it has been found that... In

their study, Casey and Wilson-Evered (2012) extended the existing model by including online-specific factors, such as trust and personal web innovativeness, to assess its effectiveness in predicting the adoption of web tools. The Unified Theory of Acceptance and Use of Technology (UTAUT) has been further developed by the inclusion of new endogenous factors (Sun, Bhattacherjee, & Ma, 2009), such as satisfaction and continuous intention to use (Maillet, Mathieu, & Sicotte, 2015). The third study stream investigated other aspects that have an impact on use and behavioural intention. These factors include task-technology compatibility and individual personality characteristics (Zhou, Lu, & Wang, 2010; Wang, 2005). Numerous scholarly investigations have extended the scope of the Unified Theory of Acceptance and Use of Technology (UTAUT) by including further contextual and moderating variables. The characteristics included in this analysis comprise, but are not limited to, culture, ethnicity, religion, job status, language, income, education level, and geographical location (Im, Hong, & Kang, 2011; Al-Gahtani, Hubona, & Wang, 2007; Riffai, Grant, & Edgar, 2012).

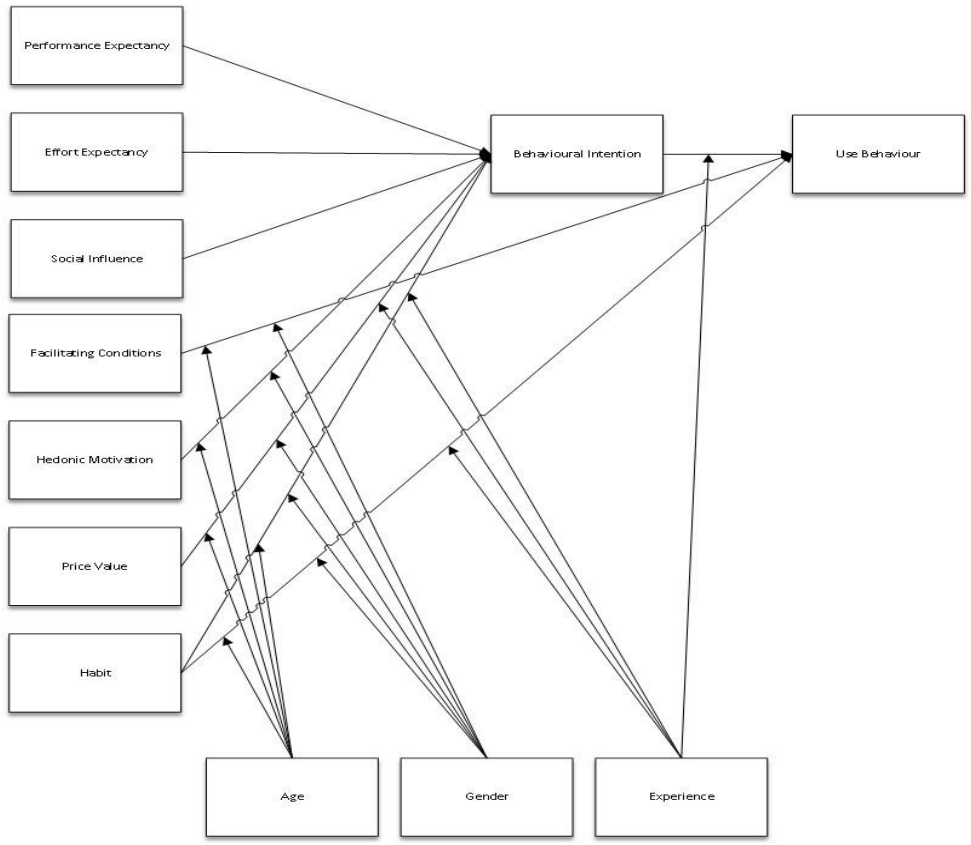

Figure 2: DOI theory (Rogers, 2003)

In summary, the Unified Theory of Acceptance and Use of Technology (UTAUT) is a conceptual framework that enhances the understanding of humans' intentions and behaviours

around technology adoption. Although UTAUT was originally designed to understand the acceptability of technology in a general context, it has the capacity to be used in several domains, including the area of e-learning. The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) within the realm of e-learning might manifest in several ways.

Exploring the concept of user acceptance: The use of the Unified Theory of Acceptance and Use of Technology (UTAUT) may be utilised to analyse the many aspects that influence the acceptance and utilisation of electronic learning platforms or systems. The paradigm encompasses four essential elements, namely performance expectation, effort expectancy, social influence, and enabling factors. By assessing these characteristics, researchers may get useful insights about users' tendencies regarding the acceptance and usage of e-learning systems.

The process of determining the influential factors The Unified Theory of Acceptance and Use of Technology (UTAUT) functions as a framework for identifying the key factors that influence the adoption of e-learning. Performance expectation refers to the perceived effectiveness of e-learning in achieving educational goals, whereas effort expectancy relates to the user friendliness and perceived ease of use of the e-learning system. By comprehending these characteristics, educators and designers may focus on enhancing the factors that promote user adoption.

Customising e-learning interventions: The Unified Theory of Acceptance and Use of Technology (UTAUT) may be used as a theoretical framework to guide the design and implementation of strategies targeted at promoting the adoption of e-learning. By discerning the key determinants that influence user behaviour, educators and e-learning providers may develop efficacious tactics to surmount possible barriers and enhance the catalysts for adoption. If it is established that social influence is a significant element, it might be advantageous to include collaborative capabilities or peer interactions into the e-learning platform in order to enhance social engagement.

Evaluating User Experience: The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) may serve as a method for evaluating user happiness and experience pertaining to electronic learning (e-learning) systems. By gaining an understanding of the factors that influence user acceptance, organisations may evaluate and improve the effectiveness, usability, and overall user satisfaction of their electronic learning platforms.

The data has the capacity to guide improvements in the system and provide a positive educational experience for the users.

The UTAUT framework has the capacity to anticipate the likelihood of technology uptake and use. The assessment of the level of acceptance and utilisation of e-learning technologies by intended users within organisations may be conducted via the evaluation of the four components of the Unified Theory of Acceptance and Use of Technology (UTAUT). The capacity to anticipate forthcoming results may possess considerable importance within the realms of decision-making, resource allocation, and planning.

The Unified Theory of Adoption and Use of Technology (UTAUT) provides a comprehensive theoretical framework for understanding and predicting people's adoption and use of technology, including e-learning platforms. The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) in the context of electronic learning (e-learning) has the potential to provide valuable insights pertaining to the creation of effective interventions, enhancement of user experience, and promotion of the adoption of e-learning technologies.

2.1.3 DIFFUSION OF INNOVATION THEORY (DOI):

The notion of DOI is concerned with the dissemination of new ideas and technology within society, including the techniques, reasons, and speed at which they spread. The phenomenon functions on both individual and communal scales. According to Oliveira and Martins (2011), the word DOI refers to a theoretical concept that elucidates the processes, rationales, and temporal dynamics of DOI. The notion of distributing innovation was first formulated by researchers, but it has now gained widespread acceptance. Rogers (1995) posits that the acceptance of innovations follows a five-stage process. The steps include the acquisition or recognition of information, the process of persuasion, the act of making a choice, the execution of such a decision, and the subsequent confirmation or adoption. Before embracing a novel concept, a person or entity often engages in a sequential progression consisting of five distinct stages. Rogers (1995) posits the existence of inventive features that may be used to examine the factors contributing to the success or failure of ideas in attaining general adoption inside organisations. This objective may be achieved within the context of the adoption phase. The Diffusion of Innovation Theory, developed by Everett Rogers, is a well-recognised framework in the field of social sciences. Theory provides a comprehensive understanding of the mechanisms via which new ideas, goods, and technologies are spread

and adopted by people and groups within different communities. This theory has a wide range of applicability across several academic fields. The idea is often used to grasp and predict the integration of new technology. This assists technology developers and innovators in identifying potential barriers and enablers of adoption. Organisations may proficiently direct their marketing tactics and customise their product offers to cater to the distinct requirements and preferences of each demographic segment. Understanding the concept of diffusion of innovation helps augment an organisation's capacity to effectively launch and advertise novel goods or services in the marketplace. Through the process of tailoring their marketing tactics, firms have the ability to increase the probability of effectively introducing and implementing their technical products or services.

2.2 REVIEW OF RELEVANT LITERATURE:

2.2.1 OVERVIEW OF THE CHATBOT:

The emergence of Artificial Intelligence in Education (AIEd), shortened as AIEd, may be historically attributed to the 1970s, as shown by Kay's (2015) scholarly investigation. Academic scholars focus their efforts on the examination, development, and evaluation of computer software to improve the educational process. The process of setting long-term objectives encompasses several key steps, including gathering feedback from learners, assessing their proficiency, identifying areas for improvement, tailoring instruction to meet the needs of individuals or groups, and ultimately employing artificial intelligence techniques to explore and improve pedagogical theories. The incorporation of scientific inquiry in artificial intelligence (AI) and its intersection with the disciplines of psychology and pedagogy in the realm of education is an essential component of the function fulfilled by AIEd. The first schematic shown in Figure 1 showcases two separate methodologies for the incorporation of artificial intelligence into the field of education. The given text does not provide enough information to be rewritten in an academic manner. Please provide AIEd, short for Artificial Intelligence in Education, pertains to the amalgamation of Artificial Intelligence (AI) with the field of Educational Research. The field under consideration is a unique and multidisciplinary sector that delineates its own aims and bounds, effectively connecting the realms of Artificial Intelligence and Education (Sjödén, 2015). The field of artificial intelligence (AI) generally centres on the study of machine learning and the advancement of intelligence that resembles that of humans. Conversely, education mostly

concentrates on the cultivation of human intellect and the augmentation of one's capacity for learning. The insights provided by AIEd help to reduce this gap by offering approaches that enable more effective and insightful interactions with people, ultimately improving educational outcomes. The domain of Artificial Intelligence in Education (AIEd) has shown a strong inclination towards investigating the capabilities of AI techniques in creating educational resources that can adeptly tailor learning experiences to accommodate the distinct needs of individual learners (Conati, Porayska-Pomsta, & Mavrikis, 2018). The examination of the effectiveness of an AIEd system in comparison to that of an individual human tutor has been a topic of significant scholarly interest since the advent of computers (VanLehn, 2011). Chatbots are a prominent and extensively used manifestation of artificial intelligence. The concept of a chatbot gained significant attention after Alan Turing's introduction of the Turing test, sometimes referred to as the "Can machines think?" test, in 1950 (Turing, 2009, pp. 23–65). The year 1966 saw the emergence of Eliza, a chatbot that is generally seen as a groundbreaking innovation. Eliza operated as a psychotherapist, using a unique approach to engaging users by reacting to their input with probing inquiries (Weizenbaum, 1966). In 1995, Wallace (2009) documented that Alice was acknowledged as the first Chatbot to achieve the designation of a "Human Computer." The advent of modern technology has given rise to the development of chatbots such as SmarterChild (Moln'ar & Szuts, 2018), Apple Siri, Amazon Alexa, IBM Watson, Microsoft Cortana, and Google Assistant (Reis et al., 2018). The rapid progress of chatbot technology since 2016 has led to the development of many types of chatbot systems designed specifically for industrial use. According to Nayyar (2019), there has been a notable increase in the use of Chatbot apps on digital platforms to enhance the educational experience of students. Currently, there are several disparate definitions associated with the notion of a chatbot. As stated by Ciechanowski et al., (2019), a chatbot refers to a software programme that replicates and understands human conversation, allowing users to interact with electronic devices in a way that simulates speaking with a genuine human being. According to existing research, the proposed method might potentially manifest as either a collaborative learning conversation (Ruan et al., 2019) or an automated system specifically developed to provide replies to human inquiries (Rosruen & Samanchuen, 2018). According to the research conducted by Clarizia et al., (2018), a Chatbot may be defined as an intelligent agent that exhibits the capacity to participate in conversations with students, offering them precise and reliable solutions to a variety of inquiries. Chatbots are often seen as interactive or chat agents that provide prompt replies to users, as highlighted by Okonkwo and Ade-Ibijola (2020) and Smutny and Schreiberova (2020). The use of chatbots

has become more common in improving learner engagement in the modern technology environment, where communication and other activities mostly depend on digital platforms. The Chatbot system exhibits the capability to operate as a mobile web application, thereby enabling the facilitation of the learning process. Dsouza et al., (2019) believe that the use of Chatbot technology in the field of education serves to augment students' interactive capabilities and streamline automated teaching methodologies. Ondas et al., (2019) reported that there is an observed improvement in connection and efficiency during interactions. Cunningham-Nelson et al., (2019) argue that online learning environments have the capacity to provide a focused, personalised, and results-oriented method of teaching, a characteristic that is much valued by modern educational establishments.

2.2.2 CHATBOT SYSTEM ARCHITECTURE

According to previous research conducted by Colace (2017) and Clarizia et al., (2018), an electronic chatbot system has been implemented utilizing the website http://ailearning.edu.vn. The website's architecture is depicted in Figure 1, while the chatbot's interaction is illustrated in Figures 2 and 3.

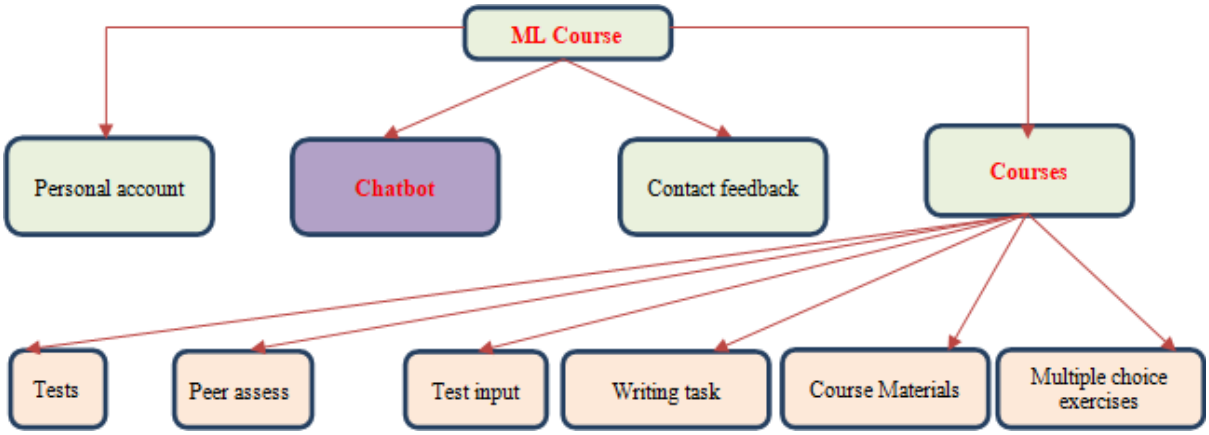

Figure 3: Structure diagram of the UML Course system

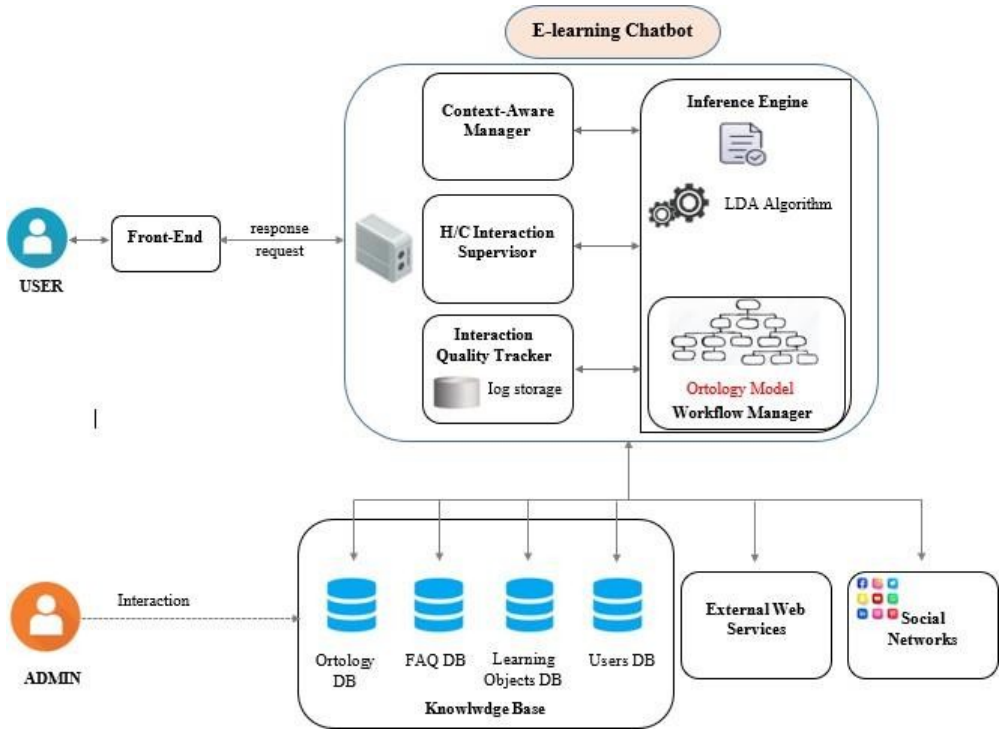

Figure 4: E - learning interactive system architecture (Colace, 2018)

2.2.3 CHATBOT FRAMEWORKS

There are many platforms that make it quick and easy to build chatbots, like Google's Dialogflow, Microsoft's Azure Bot Framework, Facebook's Bots for Messenger, and Amazon's Alexa. In addition, there are many other powerful Chatbot platforms that are widely used, such as ManyChat, Chatfuel, Converable, and GupShup. S. Raj (2019), outlining the following chatbot frameworks:

- **Language Studio is** a cloud-based framework provided by Microsoft that allows a simple Q&A chatbot to be developed based on FAQs, URLs, and structured
- **Dialogflow**, a popular cloud-based framework provided by Google, is very easy to use and allows integration with multiple platforms.
- **Rasa NLU and Core** are open-source frameworks provided for the Python development environment.

2.2.4 BENEFITS OF CHATBOTS APPLICATION IN EDUCATION

Winkler and Soellner (2018) propose that the incorporation of Chatbots within the realm of education has promise for augmenting students' academic performance and general contentment. A multitude of scholarly investigations have substantiated the effectiveness of Chatbots within the realm of education. The research, conducted by Duall and Kapros (2020), Hien et al., (2018), Mor et al., (2018), Ndukwe et al., (2019), Okonkwo and Ade-Ibijola (2020), Ranoliya et al., (2017), and Ureta and Rivera (2018), have together examined the effective implementation of Chatbots inside educational environments.

The use of chatbots has several advantages in educational environments, including cost reduction, faster response times, improved engagement, innovative learning, and higher efficiency (Llic & Markovic, 2016; Bii, 2013). The reason for this perception is because chatbots are often seen as a safe and user-friendly platform for engaging in online conversation (Cameron et al., 2017). Furthermore, chatbots have the capability to operate as a round-the-clock support service, effectively handling often asked issues, and giving users access to educational resources (Garcia-Brustenga et al., 2018; Winkler & Söllner, 2018). Consequently, this enhances overall productivity. Moreover, students are provided with the opportunity to use chatbots as a tool for enhancing their memory and facilitating the retrieval, review, and preservation of previously acquired information. Chatbots have the capacity to provide timely and efficient assistance or facilitate the acquisition of information, all the while fostering curiosity and engagement via their interactive, friendly, and interpersonal characteristics. Students regard chatbots as a novel and unique phenomena.

The integration of chatbot technology might be considered a noteworthy progression in the domain of digital education. In the domain of quality, they are generally recognised as the most innovative approach for bridging the gap between technology and education. Chatbots provide an engaging educational experience for students, similar to a personalised engagement with a teacher. Bots play a crucial role in augmenting the abilities of individual pupils via the monitoring of their development and analysis of their learning behaviours. Numerous scholarly publications have presented empirical evidence showcasing the diverse benefits that Chatbots may provide to the field of education. The aforementioned advantages encompass:

2.2.4.1 The process of combining and merging different pieces of content into a cohesive and unified whole is referred to as content integration.

The teacher has the capacity to upload relevant information, including specified subjects, assignment timelines, and other resources, into a digital platform that is easily available to authorised students. Chatbots has the capacity to assist in the distribution of relevant information to pupils. Educators could inform pupils about upcoming school events that may capture their attention, including sports tournaments, instructional seminars, and a range of extracurricular activities. According to the literature, several studies have examined the use of Chatbots in the realm of education as a means of facilitating the integration of academic content, thereby providing students with convenient access to it regardless of their location or time constraints (Akcora et al., 2018, pp. 14–19; Wu et al., 2020).

2.2.4.2 Rapid retrieval

Clarizia et al., (2018) assert that the integration of chatbots into educational settings has the potential to improve the effectiveness and outcomes of student learning. This assertion is further corroborated by the findings of Wu et al., (2020), who highlight the ability of chatbots to provide quick and convenient access to instructional material. On the other hand, the Chatbot has the capacity to function as a mechanism for social learning. According to Hussain et al., (2018), various student populations has the capacity to provide distinct perspectives and valuable insights on a particular subject matter. Additionally, chatbots may be tailored to cater to individualised issues.

2.2.4.3: The Role of Motivation and Interaction in Learning

In present-day culture, there is a growing trend among students to favour the use of smartphones for accessing and examining digital information, rather than relying on conventional textbooks or printed materials. Recent research done by Chen et al., (2020) and Pham et al., (2018) has shown that the implementation of interactive systems, such as Chatbots, has the potential to enhance student motivation and cultivate an environment that is favourable to learning and enjoyable. The use of a conversational agent as an instructional tool not only engenders irritation among students but also allows a more efficient learning of information. The dimensions of a class at a university may have influence on the pedagogical methodology used by an instructor, as well as the dynamics of student engagement within the classroom setting. Lee (2009) asserts that smaller class sizes provide more opportunities for interaction and cultivate favourable rapport between students and teachers. On the other hand, learners attach importance to their communication needs and see it as a vital component in improving their academic performance and satisfaction (Dennen et al., 2007). The efficacy of Chatbot technology in facilitating educational support has been shown by empirical investigations undertaken by Moln'ar and Szuts (2018), Adamopoulou and Moussiades (2020), and Albayrak et al., (2018), which have provided evidence of its positive impact on student engagement. Furthermore, it is plausible that they may play a substantial role in motivating students to actively participate in academic activities by consistently delivering alerts and cues.

2.2.4.4 Provision of Immediate Assistance

One of the key advantages of using Chatbots in the field of education is its notable benefit. Alias et al., (2019) assert that the incorporation of Chatbots in the realm of education enables expeditious settlement of queries presented by researchers and students. According to the study conducted by Okonkwo and Ade-Ibijola (2020), it was found that Chatbots possess the capability to provide prompt support to learners, facilitating the optimisation of various tasks such as homework submission, email communication (Molnar & Szuts, 2018; Murad et al., 2019), and timely resolution of inquiries (Sreelakshmi et al., 2019).

The functionality of enabling numerous users to use a system or platform is now accessible.

Another significant advantage of integrating Chatbot technology in the field of education is its ability to provide simultaneous access by several users to the system. This suggests that the Chatbot has the capability to support seamless conversation among several students from various geographical areas, allowing them to acquire the necessary knowledge. Rooein (2019) argues that Chatbots have the capacity to effectively handle several enquiries at once, resulting in time efficiency for users. Wu et al., (2020) argue that the use of Chatbot technology in the field of education offers a notable benefit in terms of enabling simultaneous access by numerous users.

2.2.4.5 The provision of personalized assistance

According to Cunningham-NNelson et al., (2019) and Su, M. H. et al., (2017), the incorporation of Chatbot technology is a prominent approach within the realm of education, serving to enhance and support a personalised learning experience. The implementation of the Chatbot system as a mobile application may function as a tool to enhance the learning process. Chatbots possess the capacity to expeditiously provide learners with consistent information, including details pertaining to syllabi, exercises for interactive question-and-answer sessions, and supplementary resources. Based on academic literature, the use of chatbot technology has promise in providing students with a personalised learning curriculum and fostering a more engaging educational environment (Benotti et al., 2017; Cunningham-NNelson et al., 2019). The deployment of such technologies has the capability to augment student involvement and assistance while concurrently mitigating the administrative load on instructional personnel. As a result, this facilitates educators to focus on the construction of curricula and engage in research pursuits.

2.2.5 IMPACT OF CHATBOTS ON EDUCATION

Based on current academic research, the integration of chatbots in the field of education has not been extensively implemented. The reason for this is that the technology of chatbots is still in its early phases of development in the field of education. As a result, users are required to conduct experiments to determine the benefits and limits of chatbots in this particular context (Beckingham, 2019). Nevertheless, previous scholarly works suggest that the use of chatbots in the field of education is expected to result in significant improvements in both academic achievements and the overall welfare of students (Winkler & Soellner, 2018). The efficacy of incorporating chatbots into educational settings has been demonstrated in a limited number of previously published research. The creation of 'Jill Watson', a chatbot

developed at the University of Georgia, exemplifies the use of the IBM Watson platform in the management of forum posts from students participating in a computer science course (McFarland, 2016). The major aim of the initiative was to augment student participation in the course, and the results suggest that this objective was successfully accomplished. The potential use of chatbots in large-scale educational environments, such as universities or massive open online courses (MOOCs), shows promise in overcoming the inadequacy of personalised support provided by academic institutions. The insufficiency mentioned is a significant determinant that contributes to the retention rates of fewer than 10% seen in Massive Open Online Courses (MOOCs). Sinha et al., (2019) argue that chatbots has the capacity to provide individualised learning assistance while requiring less financial and organisational resources from educators.

According to study data, there is a growing trend in the use of chatbots by users. According to the results of the research, a significant majority, over 80% of the participants, had previous familiarity with the use of a chatbot. According to the results of the poll, it was observed that almost 75% of those who had not before interacted with a chatbot belonged to the age group of 45 years or above. According to recent research, there is evidence to suggest that younger individuals are more likely to have a greater propensity for adopting new technological innovations, such as chatbots. These automated conversational agents have garnered considerable attention in current discussions (Almansor & Hussain, 2019).

In the study conducted by Silvervarg et al., (2014), it was shown that chatbots has the capacity to work as educational guides and assistants, providing a range of capabilities including information retrieval, knowledge distribution, and improved understanding. When appropriately engineered, chatbot technology has the potential to provide continuous access to instructional materials throughout the whole of the learning process. Educators may use student enquiries as a method for collecting data, expanding their knowledge base, and augmenting their expertise by using chatbot technology. The process entails the chatbot actively seeking out inquiries and augmenting its knowledge repository with supplementary responses. Based on the research conducted by Shawar and Atwell (2007) as well as Shawar (2005), a considerable fraction of students exhibit a preference for chatbot technology in comparison to search and sort-based tools. This preference stems from the chatbot's capacity to provide quick replies, as opposed to guiding users towards supplementary sources for further investigation.

Winkler and Söllner (2018) argue that chatbots have significant educational potential and may positively impact student learning and satisfaction via the provision of personalised learning support. Although there is a substantial amount of existing literature discussing the successful implementation of chatbots (Dutta, 2017; Huang, Lee, Kwon, & Kim, 2017; Kerly, Hall, & Bull, 2007), there is a scarcity of research investigating their potential in the field of education (Kowalski et al., 2011). The utilisation of chatbots in the realm of education is presently constrained as a result of insufficient comprehensive investigation on this matter (Baker, 2016; Goos et al., 1998; Bayan & Atwel, 2007; Gimeno, 2008; Wang, 2008; Torma, 2011; Govindasamy, 2014; Osodo, Indoshi, & Ongati, 2010). Numerous studies have been undertaken in the Thai context to examine the application of chatbots for diverse objectives, such as the provision of customer service (Santirattanaphakdi, 2018), system guidance (Bungodchai, 2017), performance agency (Lerdsahapan, 2015), and disease diagnosis (Mokarat, Unchai, & Marpae, 2016). Despite the considerable promise of chatbot technology as a digital learning tool for delivering tailored learning assistance, the subject of education still lacks a substantial body of study in this area. Therefore, further research is necessary to expand the understanding of chatbot technology.

2.2.6 CHATBOT INTERFACE AND EFFICIENT E-LEARNING PLATFORM

The combination of a chatbot interface with a skilled e-learning platform may effectively enhance the learning experience for students by promoting cohesion and efficacy. The following passage provides an overview of how these elements might function as interdependent constituents.

This research focuses on investigating the design and implementation of a chatbot interface specifically designed for course navigation purposes. The chatbot has the capacity to serve as an intermediate tool, aiding students in their utilisation of the e-learning platform. The chatbot has been specifically developed to provide students with relevant information on courses, modules, assignments, deadlines, and other queries linked to the platform. The chatbot's capacity to provide timely and relevant responses may lead to efficiency gains for students who would otherwise need to manually search for information.

The integration of data analytics and machine learning algorithms by the chatbot enables the delivery of tailored learning suggestions inside the electronic learning (e-learning) platform. The chatbot has the capability to provide recommendations for courses, modules, or resources that align with the educational goals, academic performance, and personal preferences of students. This characteristic enhances the effective exploration of relevant content by pupils, hence enhancing their educational experience.

Within the framework of an electronic learning environment, it is possible that students may find it necessary to seek immediate assistance and elucidation during the duration of their academic pursuits. The chatbot has the capacity to provide expeditious aid to users by promptly responding to their enquiries in real-time. The educational content has the capability to address often asked questions, provide clarifications, and aid learners in comprehending complex concepts. The availability of immediate help ensures that students may get support as needed, therefore enhancing the overall learning experience.

The use of chatbot technology into the analytics system of an e-learning platform helps students in acquiring significant information pertaining to their development and performance. The chatbot offers students the opportunity to access information pertaining to their completion status, assessment results, and general development. The availability of immediate feedback allows students to effectively track their academic progress and make educated choices about their study habits and areas in need of improvement.

The chatbot has the capacity to disseminate instructional material to students via the e-learning platform, thereby streamlining the process of delivering information and alerts. The system has the capacity to transmit relevant articles, videos, or instructional materials that correspond with the students' interests or academic prerequisites. In addition, the chatbot has the capacity to provide messages or reminders on upcoming deadlines, recent course offers, or important announcements, ensuring that students are adequately informed and engaged.

The incorporation of a chatbot facilitates the implementation of interactive learning experiences within the framework of an electronic learning environment. The chatbot interface has the capacity to provide users with quizzes, flashcards, or interactive simulations. The use of gamification strategies promotes an engaging and collaborative educational environment, improves information retention, and boosts student engagement in the digital learning context.

The integration of a chatbot into the e-learning platform might enhance the delivery of timely and advantageous feedback to students pertaining to their assignments or examinations. The system has the capacity to provide automated evaluation, identify areas in need of improvement, and suggest resources or strategies for enhancing performance. The quick feedback loop enables students to effectively assess their progress and adjust their learning tactics appropriately.

The incorporation of a chatbot interface into a capable e-learning platform has the potential to enhance accessibility, personalisation, and assistance within the domain of online education for educational institutions. The chatbot serves as a digital assistant, providing direction to students, making personalised ideas, delivering educational resources, and facilitating interactive pedagogical experiences. The incorporation of these components augments students' academic achievement and cultivates an engaging and effective digital learning environment.

2.2.7 CHATBOT PLATFORM AND EFFICIENT STUDENTS FEEDBACK

In the study conducted by Hwang et al., (2021), it was shown that virtual education offers many benefits, such as more flexibility and enhanced connection and interaction between instructors and students, regardless of their geographical location or time limitations. There are other modalities of online feedback strategies that may be provided to students, presenting similar benefits, and allowing them to engage with the material at their own speed. Various types of feedback are used in academic settings to give students with guidance on their

written projects. These forms include electronic feedback methods such as monitor changes in Microsoft Word, concise remarks sent by email, spoken feedback delivered during online meetings, screen-captured video feedback, and computer-generated automated feedback. According to Cheng and Li (2020), Liu et al., (2021), and Ware and Warschauer (2006), According to recent research conducted by Alharbi and Al-Hoorie (2020) as well as Liu et al., (2021), in virtual learning environments where students maintain anonymity and abstain from revealing their facial characteristics, there is a tendency for them to freely express their opinions to their peers and receive constructive and advantageous feedback.

Butler and Winne (1995) assert that feedback is a vital component of the educational process as it allows students to identify areas in need of development and assess their academic progress. According to Sadler (1989), it is said that feedback that is useful should provide accurate information on a learning activity or process. This feedback should address the gap between the intended and actual understanding of the subject matter or the development of abilities. By engaging in the feedback process, students strive to enhance their weak or insufficient knowledge and abilities that might hinder their academic progress. Numerous academic investigations have shown that the receipt of constructive criticism may yield beneficial outcomes in the realm of learning (Hattie & Timperley, 2007; Nicol & Macfarlane-Dick, 2006; Parikh et al., 2001). According to the research conducted by Black and Wiliam (1998), which included more than 250 studies on feedback, it was shown that feedback had a significant impact on enhancing student learning outcomes as well as their overall happiness. In their research, Henderson et al., (2019) undertook an examination of seven case studies using a range of methodologies including theme analysis, case comparison, and reliability verification. The objective of the research was to ascertain the key factors that enable the delivery of constructive criticism. The current situation highlights the need of carefully designing feedback systems, which may be categorised into three specific groups: capacity, projects, and culture. The significance of feedback in online learning settings is heightened due to the lack of face-to-face interaction among participants, as emphasised by Ypsilandis (2002). According to Nicol and Macfarlane-Dick (2006), in online environments when instructors and students are physically distant or have different schedules, it is crucial for instructors to provide high-quality feedback to support students' learning and motivation. Tseng and Tsai (2007) conducted a research which found that the provision of reinforcing feedback may have a substantial positive impact on the quality of students' projects, especially when considering online peer evaluation. The considerable size of the student body

in online learning environments might be a challenge for educators in providing meaningful and sufficient feedback to students. The improvement of feedback practises has been the subject of discussion by Belcadhi (2016), Gulwani et al., (2014), and Marin et al., (2017), who have offered several automated solutions for this purpose. The act of delivering feedback via online platforms has inherent obstacles. In a study conducted by Alharbi and Al-Hoorie (2020), it was shown that technological issues, such as the abrupt cessation of digital platforms, might provide challenges for second language learners in engaging with feedback. Ware and Warschauer (2006) argue that people may have difficulties in effectively organising and handling lengthy online discussion threads and responses, posing a challenging undertaking. According to Cheng and Li (2020), there may be instances when individuals exhibit a lack of familiarity with some forms of online feedback, such as video feedback. Furthermore, there is a prevalent expectation among students to get timely and frequent digital assessments pertaining to their academic advancement or tasks (Mory, 2004). Nevertheless, the availability of such evaluations may not be regularly guaranteed.

2.2.8 CHATBOT PLATFORM AND STUDENTS INTERACTIONS

The use of chatbots, which are conversational educational agents, has been seen in the area of education since the early 1970s (Laurillard, 2013). Pedagogical agents, sometimes known as intelligent tutoring systems, are digital entities that provide instructional support to persons in educational environments (Seel, 2011). Conversational Pedagogical Agents (CPAs) may be identified as a specific subgroup within the category of pedagogical agents. Gulz et al., (2011) assert that these entities possess the capacity to engage students in discourse-driven exchanges by using artificial intelligence. The consideration of several components, such as social, emotional, cognitive, and pedagogical characteristics, is crucial in the creation of computer-based learning environments, as emphasised by Gulz et al., (2011) and King (2002).

Conversational agents can use many forms of communication to interact with pupils, such as spoken communication (Wik & Hjalmarsson, 2009), textual communication (Chaudhuri et al., 2009), and nonverbal communication (Wik & Hjalmarsson, 2009; Ruttkay & Pelachaud, 2006). According to Dehn and Van Mulken (2000), there exists variation in the visual depiction of agents, which may be characterised by criteria such as their likeness to people or cartoons, the degree of animation, and the amount of dimensionality. In recent years, there has been a development of conversational agents that serve several educational purposes, such as acting as tutors, coaches, and learning companions (Haake & Gulz, 2009).

Furthermore, conversational agents have been utilised to meet various educational needs, such as answering inquiries (Feng et al., 2006), offering guidance (Heffernan & Croteau, 2004; VanLehn et al., 2007), and facilitating the acquisition of language skills (Heffernan & Croteau, 2004; VanLehn et al., 2007).

Within the domain of student engagement, chatbots have taken on several functions, such as teaching agents, peer agents, teachable agents, and motivating agents, as shown by the research conducted by Chhibber and Law (2019) and Baylor (2011). Based on the findings of Wambsganss et al., (2020) and Kulik & Fletcher (2016), it has been observed that teaching agents have the capability to do several duties that are conventionally fulfilled by human instructors. These jobs include the delivery of instructions, provision of examples, formulation of questions, and provision of fast feedback. In contrast, peer agents serve as educational companions for students, facilitating peer-to-peer interactions. The agent tasked with executing this strategy demonstrates a comparatively lesser degree of proficiency in comparison to the instructional agent. Nevertheless, peer agents possess the capacity to guide pupils along a trajectory of knowledge acquisition. It is a prevalent practise among students to engage in discussions with their peers in order to get definitions or seek more understanding on a certain subject matter. Peer agents have the ability to provide scaffolding for instructional dialogue among their peers.

Students have the ability to provide instructions to teachable agents, which in turn aids in facilitating a progressive learning experience. The approach used in this study entails the agent assuming the role of a beginner and actively seeking help from students in order to navigate through a learning trajectory. Baylor (2011) asserts that motivational agents play a role as companions to students, offering encouragement for good behaviour and learning, rather than directly contributing to the learning process.

According to Følstad et al., (2018), the interaction between chatbots and users may be categorised as either chatbot-driven or user-driven, based on the manner in which they engage with each other. Budiu (2018) asserts that chatbot interactions often adhere to premeditated and organised structures, following a linear format that encompasses a limited range of possible trajectories, which are dependent on the user's inputs. Chatbots of this kind are often created using if-else statements. The perception of a seamless communication experience occurs when the respondent's replies align with the conversational environment. However, complications develop when users deviate from the prescribed sequence of tasks.

User-initiated dialogues powered by artificial intelligence provide flexible chats, giving users the autonomy to pose diverse inquiries and diverge from the predefined script of the chatbot. Chatbots may be categorised into two distinct groups according on their user interaction patterns: one-way chatbots and two-way user-driven chatbots. Dutta (2017) asserts that chatbots that are user-driven use machine learning methodologies to interpret the user's input and then generate a response from a pre-existing repository of responses. On the other hand, chatbots that are led by the user and function in a bidirectional manner provide accurate replies by assembling individual words to cater to the user's needs (Winkler & Söllner, 2018).

Chatbots may be categorised into three distinct groups according on the kind of interaction they employ: text-based, voice-based, and embodied. Text-based agents allow users to participate in conversations by typing on a keyboard, while voice-based agents promote communication via the use of a microphone. Brewer et al., (2018) found that voice-based chatbots provide enhanced accessibility for older persons and those with particular requirements. In terms of their implementation, chatbots possess the capacity to be integrated across a range of messaging platforms, such as Telegram, Facebook Messenger, and Slack (Car et al., 2020). Furthermore, they may be used as independent web or mobile apps or incorporated into intelligent devices like as televisions.

2.2.9 EFFECTIVENESS OF THE CHATBOT IN IMPROVING STUDENTS E-LEARNING EXPERIENCE

Chatbots are digital agents that may act as virtual assistants by fielding questions and providing answers, as described by Clarizia et al., (2018). A text-based chatbot has been created by many authors (Salas-Pico & Yang, 2022; Topal et al., 2021). This chatbot runs in accordance with a pre-programmed set of rules, allowing it to respond to user enquiries. The term "artificial intelligence" (AI) is used to describe computer systems or computers that can learn and improve without human input (Angelov et al., 2021). In recent years, researchers have focused on chatbots (Salas-Pico & Yang, 2022; Topal et al., 2021). They have the ability to quickly analyse inquiries and provide answers (Angelov et al., 2021). Several examples of chatbots are presented in the literature, such as the Frequently Asked Questions chatbot (Han & Lee, 2022; Ranoliya et al., 2017), ELIZA, a pioneering Natural Language Processing software that emulated human-machine communication (Natale, 2019), and colMOOC, a conversational virtual agent designed to foster learners' engagement in massive open online courses (Tegos et al., 2019).

Okonkwo and Ade-Ibijola's (2020) research shows that most chatbots at universities are designed to aid educators. Mendoza et al., (2020) highlighted positive attitudes among students when they interacted with a chatbot. Several research (Hiremath et al., 2018; Mikic-Fonte et al., 2018; Pham et al., 2018; Sinha et al., 2020) have shown that students use chatbots to ask questions, get responses, and get individualised help.

Undergraduate students' learning results and motivation were examined in a research by Yin et al., (2021). Subjects were randomly allocated to either an experimental group that used a chatbot for assistance or a control group that did not. There was no discernible difference in performance levels between the two groups, according to the findings. A greater degree of motivation was indicated by students who used the chatbot compared to those who did not. In their research, Arruda et al., (2019) built a chatbot designed to help CS students model requirements with an end in mind. Students found the chatbot to be useful, and many showed interest in using it in the future, according to the study's findings. Students' mental health was improved by the use of chatbots and online courses in a research by Kamita et al., (2019). Chatbots were shown to have a higher chance of being effective in helping with self-learning, increasing motivation, and decreasing stress, as indicated by the research. The University of Georgia is responsible for the development and integration of the chatbot "Jill Watson" within a CS curriculum. Lipko (2016) found that the study's participants were more receptive than expected and wanted to use the chatbot in a variety of academic settings.

Harper et al., (2003), Sandu and Guide (2019), and Vlachopoulos and Makri (2021) all point out that asking questions in class is an important part of the learning process with the potential to raise students' grades. University students in Ghana seldom participate in class discussions with their professors. Essel et al., (2019) claim that as the number of pupils per teacher has increased, kids have received less individual attention from their teachers, contributing to the current problem. According to studies conducted by Oktaria (2021) and Soemantri (2021) and Verleger and Pembridge (2018), students are reluctant to ask questions because they are afraid of a negative response from their teachers. Some teachers respond to students' needs in this area by providing them with individualised help through instant messaging apps like WhatsApp and social media platforms like Facebook Messenger. However, a major challenge is that the teacher is not always available to respond to students' questions and provide timely, individualised grades. A lack of student-teacher engagement may have a negative impact on education. Students always demand accurate and quick feedback (Farhan et al., 2012), hence the problem of a delayed answer to their query is of

major relevance. When teachers are unable to provide enough feedback to students at all hours of the day or night, chatbots become more important (Yang & Evans, 2019). Research shows that using a chatbot may help students engage in conversational learning and review previously covered material (Göschlberger & Brandstetter, 2019; Jomah et al., 2016; Smith & Evans, 2018). As a result, this has been shown to improve adaptive learning (Fadhil & Villafiorita, 2017) and boost learning accomplishment and self-efficacy (Chang et al., 2021).

The use of chatbots may help overcome this obstacle by initiating conversations specific to each student's situation, leading to a more individualised learning experience (Hien et al., 2018; Howlett, 2017). According to Wang et al., (2021), a chatbot may act as an intermediary between a student and an instructor, allowing students to take charge of their own education and go through the material at their own speed. Verleger and Pembridge (2018) argue that chatbots may encourage students who are uncomfortable asking questions in a classroom to speak out. Students' overall learning experiences might be greatly improved with the use of chatbots in online classrooms. There is promise that a chatbot might improve the efficiency and effectiveness of online education for students.

Chatbots can provide students with tailored assistance and direction, paving the way for more personalised educational experiences. Based on each student's unique needs and learning style, teachers may tailor their recommendations, recommendations for educational resources, and assessments. Learners' engagement, motivation, and advancement towards their goals are all bolstered by individualised support.

Chatbots reduce students' dependency on human instructors and support staff by making information and assistance more quickly and easily accessible. The chatbot is prepared to respond promptly to queries, requests for clarification, and requests for help from students, allowing them to more easily interact with the system. By responding instantly to students' questions in real time, on-demand help improves the quality of the learning experience.

By providing a welcoming interface that accommodates various student preferences for learning, chatbots have the potential to improve access for students. The chatbot's ability to respond to both text and voice instructions makes it accessible to pupils with a wide range of skills. In addition, chatbots may give assistance in several languages, allowing pupils to use their native tongue while corresponding.

The use of chatbots may pave the way for the incorporation of gamification features into the e-learning experience. Teachers may make learning more engaging by including evaluations,

interesting assignments, and interactive activities. Adding gamification elements to chatbots might encourage student participation and improve their understanding of course material.

Analysing Student Performance and Adapting Instruction: Using chatbots, educators may keep tabs on their students' development and provide timely responses to their questions or concerns. They allow for the tracking of various educational KPIs including quizzes taken and courses finished. Students may use chatbots to evaluate their own performance and make adjustments to their approach to learning depending on the information they get about their strengths and weaknesses.

Chatbots may look at a student's preferences, interactions, and learning history to provide recommendations based on those factors. Articles, films, and courses that are relevant to the students' interests might be suggested by teachers as supplemental materials. This method may help students learn about previously unknown topics and broaden their horizons. The suggestions made here are meant to broaden and diversify the educational experience.

The use of chatbots in the classroom has the potential to increase student motivation and engagement by providing conversational engagements that mimic human-like interactions. By providing instantaneous and individualised feedback, chatbots have the ability to keep students engaged, answer their questions, and create a positive learning environment.

Chatbots provide for continuous assistance with schoolwork outside of regular classroom hours. The chatbot is available to students around the clock, not just during normal school hours. Learners may contact the chatbot whenever they need it, day or night, for help with everything from reviewing material to getting clarification to finding relevant resources.

By incorporating chatbots into the online classroom, schools may provide students with individualised help, instant support, engaging lessons, and consistent direction. The enhancements allow for a more interactive, inclusive, and effective electronic learning environment, which in turn leads to a better educational experience for students.

2.2.10 EFFECT OF THE CHATBOT ON STUDENTS' ACCESS TO INSTRUCTIONAL AND LEARNING RESOURCES

The use of a chatbot to broaden students' access to course materials might have far-reaching positive effects. Important ways in which chatbots are altering students' access to course materials include the following:

Better Availability and Convenience: Chatbots provide a simple and straightforward interface that helps students communicate with one another. Without having to wade through complicated systems or sift across several platforms, students may easily access learning materials and tools whenever and wherever they need them. Student involvement with required reading is facilitated by the increased convenience and heightened accessibility of resources.

By analysing students' interests, learning styles, and performance statistics, chatbots may provide highly customised suggestions for supplementary reading and viewing. The chatbot may tailor its suggestions to each individual learner, ensuring that they are relevant and useful to their individual needs and goals. Personalization has been shown to increase students' interest since it encourages them to explore a broader range of resources.

Chatbots can provide instant and relevant responses to student questions about course topics. The chatbot can quickly respond to students' inquiries and meet their requirements for clarification, additional resources, and suggestions. This method assures that students will get timely and relevant information while minimising the time and energy they spend completing individual resource searches.

Chatbots may be useful in the classroom since they might point students in the direction of relevant course resources that they would have missed otherwise. By recommending resources based on a student's interests and previous coursework, the chatbot increases their exposure to new ideas and concepts.

Chatbots may improve students' experience with learning management systems or digital libraries by providing better search and navigation tools. In response to questions on certain subjects or keywords, the chatbot may provide relevant materials or direct students to the appropriate parts. The optimised navigation mechanism makes it easier to find what you need in a large collection.

The conversational interface of chatbots might provide for engaging educational opportunities. For instance, schools may provide resources like quizzes, flashcards, or interactive simulations to help students learn and test their knowledge. By boosting user engagement and pleasure, the chatbot improves the quality of the learning experience.

Chatbots provide continuous guidance and support throughout the learning process. The chatbot is a reliable resource for students looking for information such as answers,

explanations, or suggested readings. Students benefit from a more streamlined and effective learning process when they are provided with constant advice since they know they have access to help whenever they need it. The chatbot's objective is to assist students fast and effectively while lessening the workload on the management system by responding to their questions. The presence of a chatbot will make student responses automatic and available around-the-clock. The NOUN chatbot will improve communication and raise student involvement. (Juliana et al, 2022)

Chatbots make educational and pedagogical resources more accessible to students by improving their ease of use, personalization, speed of feedback, and quality of direction. Institutions of higher learning may better support their students' learning goals and foster a more productive and engaging learning environment by taking advantage of these benefits.

2.3 REVIEW OF RELATED WORKS

Song et al., (2017) designed and built a chatbot platform to increase participation from graduate students in online courses. Based on the findings, graduate-level online courses are the optimal setting for real-time intellectual interactions between students and chatbot technology. Alkhoori et al., (2020) developed the UniBud chatbot to provide academic guidance to students using voice interaction platforms. Based on the results of the research, academic advisers are better suited to answer more difficult questions than UniBud, which has a limited ability to handle academic enquiries.

Troussas et al., (2017) developed the ALICE chatbot to aid in the acquisition of English by providing students with extensive learning and evaluation support. The study's results and the students' responses indicate that using a preexisting discourse to enhance mobile learning is a worthwhile strategy. The promise of this study, like that of other studies, is to provide students with ongoing learning support and instructional resources in a variety of media. The current inquiry is unique in that it incorporates both immediate and delayed types of support and assessment.

Lin and Chang's (2020) research project includes the development of a chatbot to help post-secondary students improve their writing. The study's participants benefited from the chatbot, the researchers discovered. The results show that having students converse with chatbots during class time boosts their drive to learn and makes the learning process easier to handle and more enjoyable for everyone involved. All of the aforementioned research has created and deployed chatbot systems, then assessed how well they helped K-12 pupils improve their language skills. The current study has the advantage of evaluating chatbot

systems' performance in a non-traditional language learning setting, focusing on graduate students.

Using the Facebook platform, Troussas et al., (2020) developed an intelligent educational software application they called i-LearnC#. Using a virtual trainer to create a specialised learning environment was meant to help students learn more effectively. The programme used a cluster analysis method to determine the most productive ways for pupils to work together. According to the results, college students who used the app benefited from it in terms of their education. The software served as an intelligent and adaptable learning environment, helping users learn more efficiently. The current study is similar to our continuing work in that both make use of the WhatsApp platform and a virtual tutoring approach to education. While other studies have focused solely on the impact of cognitive and metacognitive learning strategies on enhancing learning and the subsequent level of acceptance, this study departs from that trend by applying the Bashayer system within the realm of postgraduate education.

Troussas et al., (2022) presented a mobile learning-based educational application designed to improve students' cognitive capacities in elementary school via engaging in constructive learning activities and receiving positive reinforcement for their efforts. According to the results, the developed app successfully raised students' levels of critical thinking and intrinsic motivation. Our continuing study and the present inquiry are both concerned with measuring cognitive learning and intrinsic motivation. However, the current investigation is limited to a subset of graduate students. The focus of the research is not just on the development of students' cognitive skills, but also on the role that chatbots play in improving their metacognitive abilities as they learn.

A suggestion system using a chatbot to help students better self-regulate their learning was developed by Calle et al., (2021). In order to improve academic results, the system recommends how time, study sessions, resources, and activities should be allocated within a digital environment. The four studies all looked at the usefulness of chatbots for assisting college students with their schoolwork and social relations. This research stands out from the others by highlighting the need for investigating how chatbots affect real-world education. This research uses empirical approaches to evaluate chatbots' potential for boosting motivation and easing the use of cognitive and metacognitive processes in the classroom.

To help students improve their research skills, Vanichvasin (2020) investigated the creation of a chatbot as a digital learning aid. Thirty-six Thai college students took part in the

research. Multiple research tools were used in this study, including a chatbot, an assessment form, an efficacy questionnaire, and research tests, to determine the best course of action. Mean, standard deviation, content analysis, and a t-test were among the statistical approaches used to examine the data. Experts judged the chatbot to be highly applicable (= 4.67, SD = 0.08), and it was recommended that it be improved by adding research material and interactive learning, as shown by the study's findings. Fourteen students who were not part of the intended sample participated in a pilot research. With an average score of 4.43 and a standard deviation of 0.35, the survey revealed that students had a favourable impression of the chatbot. In order to make the chatbot more appealing, students suggested adding additional examples and pictures. With an average score of 4.37 and a standard deviation of 0.48, the chatbot was well-liked by its target audience of 36 Thai college students. Users saw chatbots as innovative, approachable, and fun to employ for learning reasons. The capacity to quickly access information and conduct targeted searches for specifics are two possible advantages. It is preferable to provide further information, such as relevant links, in response to queries that do not match specified keywords. It's also worth noting that the chatbot only provided replies when the user typed correctly. For this reason, a secondary option where consumers may choose from a list of questions or keywords should be included. The statistical analysis also showed that there was a statistically significant improvement between the pre- and post-test scores at the 0.05 level of significance. Positive learning results, such as enhanced individualised learning possibilities, have resulted from the use of chatbot technology in educational settings to improve students' research skills.

The adoption of chatbot technology in education

Evidenced by a growing body of work evaluating their potential in teaching and learning modalities, chatbot integration into e-learning settings has attracted considerable interest in recent years (Troussas et al., 2019; Smutny and Schreiberova, 2020). Lin and Chang (2020) argue that chatbots might play a variety of roles in the classroom, including those of conversational agents, support systems, and recommendation engines. According to the research conducted by Pérez-Marn (2021), chatbots may play many different functions in the lives of their human users, including those of counsellors, tutors, classmates, and even game masters. Use of innovative resources has the potential to improve students' motivation, knowledge retention, and overall performance in the classroom. Recent research from Lin and Mubarok (2021), Okonkwo and Ade-Ibijola (2021), Pérez-Marn (2021), and Fidan and Gencel (2022) all back up this idea. Colace et al., (2018) claim that using chatbots to assess student behaviour and track improvement may help students develop their abilities. Based on their reliability, accessibility, and constant availability, chatbots may provide exciting experiences for students, as pointed out by Sriwisathiyakun and Dhamanitayakul (2022). These features allow for dynamic dialogue between chatbots and students. Self-directed learning, heightened engagement in learning, goal-directedness, learning techniques, and academic accomplishment are all bolstered by the use of chatbot technology, which enables smooth and flexible interactions. Multiple investigations (Winkler and Söllner, 2018; Durall and Kapros, 2020; Pérez et al., 2020; Smutny and Schreiberova, 2020; Du et al., 2021; Haristiani and Rifai, 2021) corroborate this claim. In addition, some researchers have proposed that chatbots may help students improve their problem-solving and critical-thinking skills (Goda et al., 2014; Pérez-Marn, 2021; Cabrera et al., 2022). In addition, research suggests that chatbots can help students learn to be more independent and self-directed, reduce stress, and improve self-regulation in the classroom (Park et al., 2019; Calle et al., 2021; Cabrera et al., 2022).

There are a lot of upsides to using chatbot technology in education, and it has a lot of potential uses in the classroom. The use of a chatbot-based platform greatly improves the presentation of instructional information and resources by dividing lessons into manageable chunks and classifying homework assignments. According to the research of Pérez et al., (2020) and Haristiani and Rifai (2020), when students are given the freedom to choose their own learning goals, they are more likely to be successful (Pérez et al., 2020; Haristiani and Rifai, 2021). This upholds the principles of mastery-based education (Troussas et al., 2019) by giving learners control over their own learning in terms of

content, approach, and scheduling. giving a range of activities, encouraging students to actively participate in their own education, and giving constant feedback and guidance are all effective ways to help kids learn. In the end, this method helps students become fully proficient in the material. Chatbots' learning settings are rich with high-quality, time-saving instructional options. Without regard to time or location, chatbots make it possible for people to study together and share resources. Furthermore, they provide timely support for academic assignments from students located in the same physical location. Okonkwo and Ade-Ibijola (2021) and Troussas et al., (2022) indicate that the availability of learning modules that correspond with students' cognitive styles has been proven to improve the idea of personalised learning. Furthermore, chatbots enable mobile learning, which benefits from the advantages of continuous availability. These are seen as real-world examples of the pervasive learning notion, as stated by Heryandi (2020) and Sjöström and Dahlin (2020). When compared to other types of software, chatbots stand out due to their user-friendly design and conversational tone. These apps are also built for student-friendly platforms like Android and iOS, which are widely utilised in the classroom. In order to be useful, chatbots must be able to teach their users something by breaking down and presenting information in a way that facilitates learning and retention. Chatbots use novel methods to provide assessments, appraisals, and reactions that are in keeping with the physical characteristics of mobile devices, as stated by Troussas et al., (2020) and Wollny et al., (2021).

2.4 Summary/meta-analysis of Reviewed of Related Works

This chapter presents the results of the researcher's efforts to systematically evaluate the literature on the topic of chatbot creation for the enhancement of the e-learning experience, using the word as a case study. In this chapter, we looked at two theoretical frameworks: the Cognitive Theory of learning behaviour was an instinctive response to an experience, and the Bandura Social Learning Theory, which emphasises the necessity of monitoring and modelling the behaviours, attitudes, and emotional responses of students.

Using word as a case study, we conducted a comprehensive analysis of the literature on both the conceptual and practical aspects of designing a chatbot to enhance the e-learning experience. The majority of the research cited in the study were from inside Nigeria. Second, the ones done in Nigeria were not part of this investigation. The literature analyses also showed that the study's subvariables were examined separately, rather than in tandem. Other

studies' review samples were either too small or larger than the one used in the current research. This is when the researcher has identified a need for more empirical study to fill in the gaps in the current body of knowledge.

The purpose of this literature review is to synthesise the current research on chatbot design for improving the e-learning experience, with a particular emphasis on the NOUN as a case study. There is great potential for increased student engagement, individualised assistance, and efficient information acquisition via the use of chatbot technology in online education. This research intends to provide insights into the design of chatbots for e-learning that are unique to the setting of NOUN by methodically researching and analysing a variety of relevant works to discover common themes, best practises, and emerging trends.

CHAPTER THREE
RESEARCH METHODOLOGY

3.1 PREAMBLE

This chapter presents the research methodology employed in the study on the design of a chatbot to enhance the e-learning experience of students at the National Open University of Nigeria (NOUN). It includes the problem formulation, proposed solution, techniques used, tools utilized in the implementation, research design, validation techniques, performance evaluation parameters, and system architecture.

3.2 PROBLEM FORMULATION

This research aims to investigate the issue of insufficient personalised and interactive assistance inside conventional e-learning systems, which therefore results in diminished student engagement and unsatisfactory learning achievements. The chatbot need to adjust its functionality to accommodate the unique requirements and rate of progress of each individual student. According to Betts et al., (2020), it is recommended to conduct an analysis of user interactions, monitor progress, and provide customised feedback and assistance in response. The use of customization strategies may effectively target and mitigate individual challenges or misunderstandings that learners may encounter in relation to the subject matter, NOUN.

The chatbot should possess an interface that is user-friendly, characterised by its intuitive nature and ease of navigation. The system should use natural language processing skills in order to properly comprehend user inputs and provide relevant responses. According to Desk (2023), Furthermore, it is essential that the interface has an aesthetically pleasing design and is easily available on a multitude of devices or platforms that are often used for e-learning purposes. Through the consideration and integration of these fundamental elements, the design of the chatbot has the potential to significantly augment the e-learning encounter for students enrolled in NOUN, affording them an interactive and tailored instrument.

3.3 PROPOSED SOLUTIONS

The suggested approach is the creation of a customised chatbot designed exclusively for the e-learning platform at the National Open University of Nigeria (NOUN). The major objective of this chatbot is to provide individualised assistance to students, facilitating their access to educational materials and resources, resolving their inquiries, and eventually improving their overall experience with online learning.

Developing a chatbot with the aim of enhancing the e-learning encounter, using NOUN as a case study, necessitates a deliberate and strategic methodology. The process involves the consideration of several criteria, such as the requirements of the users, the desired learning outcomes, and the technical aspects of implementation. In order to do this, a number of recommended goals have been developed for the purpose of creating the chatbot.

First and foremost, the implementation of comprehensive user research is of utmost importance in order to ascertain and pinpoint the precise pain points and issues encountered by learners at the National Open University of Nigeria (NOUN). The process of collecting insights from individuals' experiences will facilitate the customization of the chatbot to meet their specific needs. Furthermore, it is important to get input from both students and administrators in order to have a comprehensive understanding of their expectations and requirements pertaining to the chatbot in question. According to Bezverhny, Dadteev, Barykin, and Klimov (2020), drawing insights from the experiences of others might be a useful learning opportunity.

The establishment of precise learning goals for the chatbot is of utmost importance. The goals should involve the provision of vital course information, fast response to inquiries, provision of study tools, and assistance with assignments, all in accordance with the curriculum and learning outcomes of NOUN students. Establishing a coherent and user-friendly conversational structure inside the chatbot is crucial in facilitating smooth navigation across diverse encounters. The seamless user experience provided by this organic flow will facilitate the interaction between students and other users, enabling them to effortlessly connect with the chatbot and get the desired information. The integration of the chatbot with NOUN's pre-existing Learning Management System (LMS) is a crucial measure aimed at augmenting its overall capabilities. Through this approach, students are able to experience uninterrupted accessibility to educational resources, check their academic performance records, and get timely notifications, all within a cohesive and integrated framework.

The consideration of technical concerns should not be disregarded. The seamless user experience is contingent upon the criticality of guaranteeing interoperability and data synchronisation between the chatbot and the Learning Management System (LMS). In addition, the ongoing enhancement of the chatbot is vital for optimising its efficacy. Consistently gathering input from users facilitates the identification of areas that may be improved and refined. The optimisation of the chatbot's performance and accuracy may be

enhanced by the analysis of user interactions and use patterns, as supported by the research conducted by Dersch, Renkl, and Eitel (2022). Through careful consideration of these goals, the implementation of the chatbot may be implemented in a deliberate manner, tailored to meet the unique requirements of NOUN's e-learning environment. This will result in the provision of important assistance to both students and administrators.

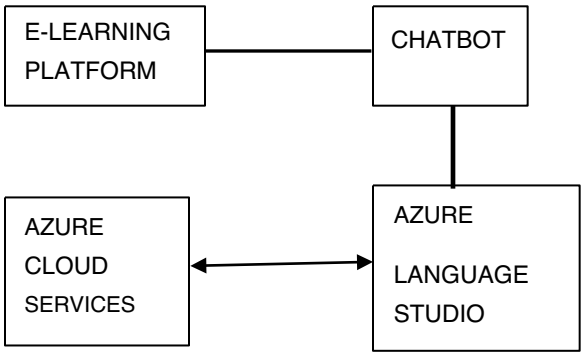

Figure 5: E-learning chatbot architecture

3.4 RESEARCH DESIGN

The research used a survey design methodology. The chosen technique was deemed suitable as it facilitated the researcher in effectively describing, examining, documenting, analysing, and interpreting the variables identified in the study. Moreover, the utility of this data stems from its collection from a quite extensive population. According to Ezejulue and Ogwo (1990), the primary objective of survey research is not only to gather data, but rather to uncover significance within the data gathering process. This approach aims to enhance comprehension, interpretation, and explanation of facts and occurrences. It was emphasised that the phrases "descriptive" and "survey" are used interchangeably to refer to the aforementioned style of study.

3.5 CONSIDERATION FOR MIXED METHODS

The use of a mixed methods approach may considerably increase the e-Learning experience of students at the National Open University of Nigeria (NOUN) while designing a chatbot. Mixed methods research integrates qualitative and quantitative data gathering and analysis methodologies, so facilitating a more full comprehension of the issue at hand and its possible remedies. This research incorporates consideration for mixed techniques in the following manner.

Usage Patterns (Quantitative): Utilize quantitative data analysis to track usage patterns of existing e-Learning resources to identify areas where a chatbot can effectively assist students and enhance engagement.

Chatbot Interface Design (Qualitative): During the design phase, involve students in focus groups or usability testing sessions to get feedback on the chatbot's interface design. Understanding how students interact with the chatbot and what improvements can be made will be valuable in refining the user experience.

Feedback and Iteration (Mixed): Continuously collect both quantitative and qualitative feedback from students while the chatbot is in use. This iterative process allows for continuous improvement and ensures that the chatbot meets the evolving needs of students.

Impact Assessment (Mixed): After the chatbot has been implemented, use mixed methods to assess its impact on the e-Learning experience. Quantitative data can be collected on metrics such as student engagement, course completion rates, and grades, while qualitative data can provide insights into the students' perceptions and experiences with the chatbot.

Contextual Understanding (Qualitative): Employ qualitative methods to understand the specific context of NOUN's e-Learning environment. This can include factors such as internet connectivity, device availability, and unique challenges faced by distance learners.

By incorporating mixed methods research, the design and implementation of the chatbot for NOUN's e-Learning can be more informed and well-rounded, resulting in a more effective and student-centered solution. It allows for a deeper understanding of the students' needs, preferences, and experiences, leading to a more meaningful and impactful chatbot that enhances their learning journey.

3.6 RESEARCH POPULATION AND SAMPLING PROCEDURE

The study population comprises 565,385 students for the school year 2022/2023. According to Unyimadu (2005:36), the term "population" refers to a group of things, persons, or events that possess a shared trait of interest to the researcher. The many terms used to describe this concept include target population, accessible population, limited population, and limitless population.

A total of 379 students, who were identified as NOUN students, were selected for the study using the method proposed by Kercie and Morgan (1970). The research employs convenience and snowball sampling techniques for participant selection. According to Nikolopoulou

(2023), convenience sampling is a non-probability sampling technique that involves selecting units for inclusion in the sample based on their accessibility to the researcher. On the other hand, snowball sampling is a non-probability sampling method in which new units are recruited by existing units to be part of the sample. Snowball sampling is a valuable method for doing research on individuals with special characteristics that may provide challenges in identification, such as those afflicted with a rare illness.

3.7 MEASUREMENT FOR STUDY

The research used a questionnaire as a means of assessing the design of the chatbot. The tools were used to gather data pertaining to the dependent and independent variables included in the investigation. The research used Likert's (1932) modified scale of measuring.

The study instrument had three distinct portions, denoted as A, B, and C. Section A of the study is dedicated to examining the personal data of the participants. In Section B, the constructions of dependent and independent variables were assessed via the use of five questions for each construct, resulting in a total of 20 items. Each variable was assessed using a 4-point internal scale of measurement, consisting of the following categories: Strongly Agreed (SA) with a value of 4 points, Agreed (A) with a value of 3 points, Disagree (D) with a value of 2 points, and Strongly Disagreed (SD) with a value of 1 point for favourably written items. The use of reversed scoring was employed for items that were phrased in a negative manner.

3.8 MEASURES OF DEPENDENT, MEDIATING, AND INDEPENDENT VARIABLE

This section presents a brief explanation of the dependent and independent variables that were used in this study, and the statistical tools that were adopted in the data analyses.

Variables	**Brief Explanation**
Existing e-learning environment at NOUN	This measures online platform designed to facilitate distance learning and provide flexible access to educational resources and course materials for NOUN students across the country and beyond. Simple percentage analysis was used to analyse the data.
Design and develop a chatbot system	This evaluates measure platform for building the chatbot. Options include using a chatbot development framework, a natural language processing (NLP) library, or utilizing a chatbot development platform with pre-built tools and

	integrations. Simple percentage analysis was used to analyse the data.
effectiveness of the chatbot	Measure the frequency and duration of user interactions with the chatbot, assess how well the chatbot handles user queries and successfully provides relevant and accurate answers, Analyse the average response time of the chatbot. Simple percentage analysis was used to analyse the data.
potential benefits and applications of chatbot technology	This measures and evaluates instant and round-the-clock customer support, helping students and facilitator respond to inquiries and resolve issues at any time. Simple percentage analysis was used to analyse the data.

3.9 PRE-TESTING THE INSTRUMENT AND CONTENT VALIDITY

The researcher used the Pearson Product Moment Correlation (PPMC) analysis in order to assess the reliability of the instruments. During the trial testing phase, a sample of 50 students who were not originally included in the main study were randomly chosen from the study region. The selected students were then subjected to the administration of the instruments.

The two study tools were administered for validation purposes inside the Department of Management Information System at Lagos State University. The goal of this study was to ensure that the questions included in the questionnaire were appropriately phrased to align with the respondents' level of comprehension and effectively address the research objectives in a comprehensive manner. The primary objective of instrument validation was to ascertain the face and content validity. Ultimately, the instruments were deemed to be valid for use.

3.10 PILOT STUDY

In the preliminary investigation, a sample size of 50 participants who were not included in the primary study were chosen at random from the designated research region. The acquired data underwent analysis, and the findings of the research were found to be statistically significant.

3.11 DATA COLLECTION STRATEGY

The questionnaires were disseminated via the use of Google Forms and thereafter administered to a selected set of respondents through WhatsApp group and email. The replies obtained from these individuals were then included into the research. The use of the snowball sampling approach precluded researchers from conducting in-person visits to obtain

information from respondents. Due of the pre-existing connections among participants, the snowball approach proved to be efficacious in identifying and finding them.

3.12 DATA ANALYSIS STRATEGY

The rationale for using the Pearson correlation model is grounded in its ability to quantify the presence of a link. In essence, the Pearson product moment correlation analysis quantifies the association between two variables by use of an equation whereby one variable has the potential to exert impact on the other.

The selection of statistical techniques was deemed suitable due to the use of an interval measurement scale and the presence of independent observations.

3.13 SUMMARY

In brief, this chapter provided an overview of the research approach used in the investigation concerning the development of a chatbot aimed at augmenting the e-learning encounter at NOUN. The chapter provides an overview of many aspects related to the issue formulation, suggested solution, tools used, study design, validation procedures, performance assessment parameters, and system architecture. The subsequent chapter will provide an exposition of the findings and analyses derived from the research, which were obtained via the use of a questionnaire. Furthermore, this chapter will delve into the implications that may be drawn from the obtained data.

CHAPTER FOUR
DATA PRESENTATION, ANALYSIS AND FINDINGS

This chapter involves the presentation, analysis, and interpretation of result of the data collected. The data are arranged and analysed in tables following the research questions

ANSWERING OF RESEARCH QUESTIONS

4.1.1 Research Question One:

What are the current challenges faced by students in the e-learning environment at NOUN?

Table 1: analysis of respondent's responses on current challenges faced by students in the e-learning environment at NOUN

S/N	INNOVATIVENESS	SA(%)	A(%)	U(%)	D(%)	SD(%)	Total
1	The e-learning platform provides clear instructions on how to participate in online activities and submit assignments.	105 (27.70)	88 (23.2)	67 (17.6)	60 (15.8)	59 (15.56)	379 (100)
2	The e-learning platform offers interactive features (e.g., discussion forums, live chat) for student collaboration and engagement.	103 (27.17)	88 (23.2)	72 (18.9)	61 (16.0)	55 (14.51)	379 (100)
3	The communication channels (e.g., emails, messaging systems) between students and instructors are effective and responsive.	102 (26.91)	83 (21.8)	70 (18.4)	68 (17.9)	56 (14.77)	379 (100)
4	The e-learning platform	104	83	73	67	52	379

	provides timely and constructive feedback on assignments and assessments.	(27.44)	(21.8)	(19.2)	(17.6)	(13.72)	(100)
5	The availability of support services (e.g., technical support, academic advising) for e-learning students is satisfactory.	103 (27.17)	80 (21.1)	77 (20.3)	62 (16.3)	57 (15.03)	379 (100)
	Aggregate	517 (27.28)	422 (22.2)	359 (18.9)	318 16.78)	279 (14.73)	1895 (100)
	Proportional Ratio	103.4	84.44	71.8	63.6	55.8	**379**

Source: Researcher's Computation (2023).

Analysis of responses of respondents on current challenges faced by students in the e-learning environment at NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 517 representing 27.28% and a proportional ratio of 103.4. This was followed by aggregate of 422 representing 22.27 and a proportional ration of 84.44 who opted for agreed option, Undecided had an aggregate of 359 representing 18.94 and a proportional ratio of 71.8, Disagree option had an aggregate of 318 representing 16.78 and a proportional ratio of 63.6, Strongly Disagree option had an aggregate of 279 representing 14.73 and a proportional ratio of 55.8.

Therefore, based on the above analysis, current challenges faced by students in the e-learning environment at NOUN is statistically significant.

4.1.2 Research Question Two:

How can chatbot technology be applied to improve the e-learning experience at NOUN?

Table 2: analysis of respondent's responses on chatbot technology application and improving the e-learning experience at NOUN

SN	Competitive aggressiveness	SA (%)	A (%)	U (%)	D (%)	SD (%)	Total
1	Chatbots can provide immediate responses to	106 (27.96)	96 (25.32)	78 (20.58)	55 (14.51)	44 (11.60)	379

	students' queries and enhance the accessibility of educational resources.						
2	Chatbots can personalize the learning experience by offering tailored recommendations and content based on individual students' needs and preferences.	103 (27.17)	97 (25.59)	73 (19.26)	0 (16.09)	46 (12.13)	379
3	Chatbots can enhance student engagement and motivation by providing interactive and conversational learning experiences.	109 (28.75)	95 (25.06)	80 (21.10)	50 (13.19)	45 (11.87)	379
4	Chatbots can assist students in tracking their progress and provide feedback on their performance, thereby facilitating self-assessment and self-improvement.	105 (27,70)	90 (23.74)	72 (18.99)	60 (15.83)	52 (13.72)	379
5	Chatbots can support collaborative learning by facilitating group discussions, peer-to-peer interactions, and knowledge sharing among students.	108 (28.49)	96 (25.32)	80 (21.10)	50 (13.19)	45 (11.87)	379
	Aggregate	**531 (27.72)**	**474 (25.39)**	**383 (20.29)**	**276 (14.36)**	**231 (12.24)**	**1895 (100)**
	Proportional Ratio	**105.1**	**94.9**	**76.9**	**55.8**	**46.3**	**379**

Source: Researcher's Computation (2023).

Analysis of response of respondents on chatbot technology application and improving the e-learning experience at NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 531 representing 27.72% and a proportional ratio of 105.1. This was followed by aggregate of 474 representing 25.39 and a proportional ration of 94.9 who opted for agreed option, Undecided had an aggregate of 383 representing 20.29 and a proportional ratio of 76.9, Disagree option had an aggregate of 276 representing 14.36 and a proportional ratio of 55.8, Strongly Disagree option had an aggregate of 231 representing 12.24 and a proportional ratio of 46.3.

Therefore, based on the above data analysis, there is chatbot technology application and improving the e-learning experience at NOUN.

4.2.3 Research Question Three:

What are the design considerations and requirements for developing an effective chatbot for NOUN?

Table 3: analysis of respondent's responses on design considerations and requirements for developing an effective chatbot for NOUN

S/N	DESIGN CONSIDERATIONS AND REQUIREMENTS	SA (%)	A (%)	U (%)	D(%)	SD (%)	Total
1	The chatbot system is user-friendly and easy to navigate.	104 (27.44)	90 (23.74)	81 (21.37)	71 (18.7)	33 (8.70)	379
2	The chatbot provides accurate and relevant information related to my courses and studies.	108 (28.49)	88 (23.21)	74 (19.52)	51 (13.45)	58 (15.30)	379
3	The chatbot understands my queries and responds effectively.	102 (26.91)	93 (24.53)	86 (22.69)	50 (13.19)	48 (12.66)	379
4	The chatbot system has improved my overall e-						

	learning experience at NOUN.	102 (26.91)	91 (24.01)	82 (21.63)	59 (15.56)	45 (11.87)	379
5	The chatbot system has helped me in accessing and locating learning resources more efficiently.	109 (28.75)	90 (23.74)	83 (21.89)	50 (13.19)	47 (12.40)	379
	Aggregate	**525 (27.90)**	**452 (23.85)**	**406 (21.42)**	**281 (14.43)**	**231 (12.40)**	**1895 (100)**
	Proportional Ratio	**105**	**90.4**	**81.20**	**56.2**	**46.3**	**379**

Source: Researcher's Computation (2023).

Analysis of responses respondents on design considerations and requirements for developing an effective chatbot for NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 525 representing 27.90% and a proportional ratio of 105 This was followed by aggregate of 452 representing 23.85 and a proportional ration of 90.4 who opted for agreed option, Undecided had an aggregate of 406 representing 21.42 and a proportional ratio of 81.20, Disagree option had an aggregate of 281 representing 14.43 and a proportional ratio of 52.6, Strongly Disagree option had an aggregate of 231 representing 12.40 and a proportional ratio of 46.2. Therefore, based on the analysis of study, the design considerations and requirements for developing an effective chatbot for NOUN is effectively tailored to suit leaner's needs.

4.2.4 Research Question Four:

To what extent does the implemented chatbot enhance student engagement and satisfaction?

Table 4: analysis of respondent's responses on implementation of chatbot enhance student engagement and satisfaction.

S/N	implementation of chatbot	SA(%)	A(%)	U(%)	D (%)	SD (%)	Total
1	The chatbot provided helpful and relevant information.	102 (26.91)	94 (24.80)	89 (23.48)	70 (18.46)	24 (6.33)	379
2	The chatbot responded promptly to my queries.	109 (28.75)	89 (23.48)	73 (19.26)	56 14.77)	52 (13.72)	379
3	The chatbot understood my questions accurately.	200 (52.77)	91 (24.01)	23 (6.06)	43 (11.34)	22 (5.80)	379
4	The chatbot enhanced my engagement with the e-learning platform.	102 (26.91)	96 (25.32)	86 (22.69)	73 (19.26)	22 (5.80)	379
5	The chatbot effectively addressed my concerns and provided solutions.	106 (27.96)	93 (24.53)	84 (22.16)	50 (13.19)	46 (12.13)	379
	Aggregate	619 (32.50)	463 (24.43)	355 (18.76)	292 (58.4)	166 (8.80)	1895
	Proportional Ratio	**123.8**	**92.6**	**71.0**	**58.4**	**33.2**	**379**

Source: Researcher's Computation (2023).

Analysis of respondents on implemented chatbot enhance student engagement and satisfaction reveals that the respondents Strongly Agreed (SA) responses had an aggregate of

619 representing 32.50% and a proportional ratio of 123.8 This was followed by aggregate of 463 representing 24.43 and a proportional ration of 92.6 who opted for agreed option, Undecided had an aggregate of 355 representing 18.76 and a proportional ratio of 71.0, Disagree option had an aggregate of 292 representing 58.4 and a proportional ratio of 58.4, Strongly Disagree option had an aggregate of 166 representing 8.80 and a proportional ratio of 33.2. Therefore, implementation of chatbot enhance student engagement and satisfaction.

RESEARCH TESTING

4.2.5 Research question One

Current challenges faced by students in the e-learning environment do not significantly affects learning outcomes at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables

TABLE 4.5

Pearson Product Moment Correlation Analysis of Current challenges faced by students in the e-learning environment and their learning outcomes at NOUN

Variable	$\sum x$	$\sum x^2$	$\sum xy$	r
	$\sum y$	$\sum y^2$		
Learning outcomes at NOUN (x)	9011	270655		
			134663	0.94*
Current challenges faced by students (y)	9113	58989		

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.5 presents the obtained r-value as (0.94). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.94) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between **current** challenges faced by students in the e-learning environment significantly affects learning outcomes at NOUN.

4.2.6 Research Question Two

Chatbot technology application does not significantly improve the e-learning experience at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyze the data in order to determine the relationship between the two variables

TABLE 4.6

Pearson Product Moment Correlation Analysis of chatbot technology application does not significantly improve the e-learning experience at NOUN

Variable	$\sum x$	$\sum x^2$	$\sum y$	$\sum y^2$	$\sum xy$	r
improve the e-learning experience (x)	9011	270655			140162	0.83*
chatbot technology application (y)		9113	58989			

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.6 presents the obtained r-value as (0.83). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.82) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between chatbot technology application does significantly improve the e-learning experience at NOUN

4.2.7 Research Question Three

The design considerations and requirements for developing an effective chatbot does not improve e-learning at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables.

TABLE 4.7

Pearson Product Moment Correlation Analysis of the design considerations and requirements for developing an effective chatbot for improve e-learning at NOUN

	$\sum x$	$\sum x^2$

Variable	∑x	∑x²	∑y	∑y²	∑xy	r
Improve e-learning at NOUN (x)	9011	270655				
					141752	0.91*
Design considerations and requirements (y)	9113	58989				

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 12 presents the obtained r-value as (0.91). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.82) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between design considerations and requirements for developing an effective chatbot does improve e-learning at NOUN

4.2.8 Research Question Four

Implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables

TABLE 4.8

Pearson Product Moment Correlation Analysis of Implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN

Variable	∑x	∑x²	∑y	∑y²	∑xy	r
student engagement and satisfaction at NOUN (x)	9011	270655				

		134563	0.96*
Implementation of Chabot (y)	9153	58062	

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.7 presents the obtained r-value as (0.96). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.96) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN.

4.3 Discussion of Findings

The significance of the data analysis in table 5 may be attributed to the observation that the calculated r-value (0.94) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311 degrees of freedom. This suggests that there exists a substantial correlation between the prevailing difficulties encountered by students in the e-learning setting and their resultant impact on learning results at NOUN. The observed outcome aligns with the findings of Zulaikha, Mansor, Khairul, and Alias (2021), indicating its relevance. E-learning often necessitates the use of diverse technology, including learning management systems, video conferencing tools, and online collaboration platforms, by students. Various technical challenges, such as those related to software compatibility, hardware constraints, or insufficient technical expertise, might hinder the development of students and give rise to feelings of dissatisfaction. The presence of these problems has the potential to divert students' attention away from their academic pursuits, so exerting an influence on their educational achievements. Therefore, it is possible that e-learning platforms may not provide enough array of materials or full assistance for learning. Challenges in obtaining textbooks, research resources, and academic support services may impede students' educational advancement. The restricted availability of resources and inadequate learning assistance may have a detrimental effect on students' capacity to comprehend intricate topics and ultimately lead to diminished learning achievements. The outcome's importance led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

The significance of the data analysis in table 6 may be attributed to the observation that the calculated r-value (0.83) exceeded the critical r-value (0.086) at a significance level of 0.025,

with 311 degrees of freedom. This suggests that there exists a substantial correlation between the use of chatbot technology and the enhancement of the e-learning experience at NOUN. The relevance of the findings aligns with the research conducted by Frąckiewicz, M. (2023), which posited that chatbots have the capacity to provide customised learning experiences via the provision of personalised information, resources, and advice that cater to the unique requirements of individual students. Through the examination of user data and the use of natural language processing techniques, chatbots have the capability to supply personalised information, address precise inquiries, and offer focused response. Therefore, chatbots has the capability to be developed in a manner that facilitates interactive chats, quizzes, and simulations with students, therefore enhancing the learning experience by increasing engagement and immersion. The use of multimedia features enables chatbots to provide educational information in several forms, including movies, photos, and interactive modules, therefore augmenting students' understanding and retention capabilities. The observed outcome of the study led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis, indicating its substantial importance.

The significance of the data analysis in table 7 may be attributed to the observation that the calculated r-value (0.91) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311 degrees of freedom. This suggests that there exists a substantial correlation between design considerations and needs in the development of a proficient chatbot, as well as the enhancement of e-learning at NOUN. The relevance of the findings aligns with the research conducted by Babington-Ashaye, De Moerloose, Diop, & Geissbuhler (2023b), since the integration of NLP technology facilitates the chatbot's ability to comprehend and address user inquiries in a way that closely resembles human interaction. Natural Language Processing (NLP) facilitates enhanced understanding of diverse phrase forms, user intentions, and contextual information. This facilitates the development of a more captivating and participatory user experience. Therefore, this guarantees the smooth integration of the chatbot and e-learning platform inside the pre-existing systems and infrastructure of NOUN. This integration enables a cohesive user experience and streamlines the retrieval of pertinent student data, educational materials, and scholarly resources. The observed outcome had sufficient importance to warrant the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

The significance of the data analysis in table 7 arises from the observation that the calculated r-value (0.96) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311

degrees of freedom. This suggests that there exists a substantial correlation between the use of a chatbot at NOUN has been shown to have a considerable positive impact on student engagement and satisfaction. The observed outcome aligns with the findings of Jenneboer, Herrando, and Constantinides (2022). The inclusion of a chatbot has enhanced accessibility for students by offering continuous support. Students have the opportunity to conveniently access information and get help, therefore diminishing their need on in-person assistance during designated office hours. The chatbot system effectively delivered tailored and pertinent information to pupils, effectively answering their individual inquiries. The heightened amount of assistance resulted in a notable rise in student contentment, as they perceived their requirements to be well addressed. The outcome's importance led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

CHAPTER FIVE

SUMMARY, CONCLUSION AND RECOMMENDATION

Introduction

This chapter presents a summary of the major findings, conclusion, and recommendations of this study.

5.1 SUMMARY

The purpose of this study was to investigate the construction of a chatbot as a means of enhancing the e-learning experience, with a specific focus on the use of a word as a case study. The architecture of the e-learning environment is tailored to address the unique needs and problems of NOUN. It places emphasis on enhancing student involvement, satisfaction, and support. Chapter three provides an overview of the methods used in the building of the chatbot, along with a comprehensive examination of its architecture, functionality, and integration inside the established e-learning platform at NOUN.

In order to conduct this study, four specific research goals were identified, from which null hypotheses were constructed and then used in the investigation. The literature review was conducted by considering the factors relevant to the study goals. The achievement of this task was facilitated via the utilisation of previous scholarly studies, academic literature, and educational resources. The architecture of the e-learning environment has been carefully tailored to address the unique objectives and problems of NOUN. The primary objective is to enhance student involvement, satisfaction, and support. This chapter provides an overview of the approach used in the construction of the chatbot, as well as a comprehensive examination of its architecture, functionality, and integration inside the established e-learning platform of the National Open University of Nigeria (NOUN). The present document provides a description of the technique used in the creation of the chatbot. This paper examines the iterative design process, including key stages such as requirements collecting, analysis, and user input. The use of user-centric design concepts and the active engagement of stakeholders, including students and teachers, are emphasised in the design process.

This paper examines the incorporation of a chatbot into the preexisting e-learning infrastructure of the National Open University of Nigeria (NOUN). This section elucidates the technological components involved in the integration of the chatbot with the platform's user authentication system, database, and messaging infrastructure. This response focuses on

discussing the design decisions that have been used to create a smooth user experience and promote interoperability.

This section outlines the evaluation and testing strategy for the chatbot system that has been built. It provides an overview of the techniques that will be used to analyse the system's usability, accuracy, and user satisfaction. The discourse is on the engagement of students and teachers in the assessment process and the gathering of feedback to provide iterative improvements. The study had a total of 383 participants. The data obtained from the participants underwent rigorous statistical analysis, and the outcomes of this study were shown to be statistically significant at a significance level of 0.025. The results were thoroughly examined in order to ascertain their alignment or divergence with the conclusions reached by previous studies.

5.2 CONCLUSIONS:

The objective of this study was to introduce a chatbot to enhance students' online learning options at the National Open University of Nigeria (NOUN). The research covered the following crucial issues:

- Current Challenges: Clear instructions, interactive features, communication channels, prompt feedback, and support services are among the difficulties students currently experience in NOUN's e-learning environment. These challenges were statistically significant.

- Chatbot Technology: Most respondents believed that chatbot technology may improve NOUN's e-learning program. They were aware of the quick responses, personalized education, engagement-boosting, progress-tracking, and group learning benefits that chatbots may offer.

- Design Considerations: According to the study, NOUN students were in favor of the requirements and design elements required to build a successful chatbot. They emphasized the value of user-friendly interfaces, accurate information delivery, understanding of user enquiries, enhancing the overall e-learning experience, and efficiently locating learning resources.

- Enhanced Engagement and Satisfaction: It was noticed that the introduction of the chatbot had a considerable beneficial effect on students' engagement. Respondents agreed that the chatbot increased their interaction with the e-learning platform, promptly responded to their questions, correctly understood them, and successfully resolved their issues.

Based on the findings, it is apparent that the integration of a chatbot into the e-learning platform at NOUN may greatly enhance the overall educational experience. The results indicate that the incorporation of a chatbot system has the potential to enhance student

engagement, contentment, and accessibility to support services, while concurrently yielding cost and time efficiencies for the educational institution.

5.3 RECOMMENDATIONS:

The suggestions for the creation of a chatbot to enhance the e-learning experience, as derived from the results of a research conducted at the National Open University of Nigeria (NOUN), are as follows:

There is a need for the administration of NOUN to do a comprehensive examination of the distinct requirements and obstacles encountered by NOUN students throughout their e-learning endeavour. When examining the characteristics of the target audience, it is important to consider their demographic profile, level of technical expertise, and prevalent challenges or difficulties they may encounter. The comprehension of this concept will serve as a framework for the strategic planning, creation, and incorporation of the chatbot.

The design of the chatbot by the management of the NOUN should prioritise a user interface that is both clear and straightforward, effectively emulating natural language exchanges. The primary objective is to ensure that the chatbot comprehends a diverse array of inquiries from students and delivers pertinent information in a conversational style.

The administration of NOUN should maintain the continuous availability of the chatbot to accommodate the varied study schedules of NOUN students. The provision of this availability would facilitate rapid help, timely resolution of inquiries, and enhance overall student satisfaction.

The seamless integration of the chatbot with the NOUN e-learning platform aims to provide a cohesive user experience. The connection facilitates the chatbot's ability to get course materials, participate in discussion forums, submit assignments, and access other pertinent resources, therefore providing extensive assistance inside the platform.

Develop and deploy systems to systematically collect feedback from students on their interactions and overall experience with the chatbot. It is essential to conduct regular analysis of this input in order to discover potential areas for development, enhance the performance of the chatbot, and tweak its replies to effectively cater to the shifting demands of students.

Implement thorough onboarding and training sessions to acquaint pupils with the chatbot's capabilities and operations. This document aims to provide comprehensive guidance and

tools to assist students in maximising their engagement with the chatbot and effectively use its whole range of capabilities.

It is important to consistently assess the performance, use trends, and user feedback of the chatbot in order to evaluate its influence on the e-learning experience. To assess the efficacy of the chatbot and provide evidence-based enhancements, it is essential to monitor many indicators, including student engagement, satisfaction, retention rates, and academic success.

5.4 SUGGESTIONS FOR FURTHER STUDY

The exploration of developing a chatbot with the aim of enhancing the e-learning encounter at the National Open University of Nigeria (NOUN) presents a promising avenue for scholarly investigation. The following recommendations propose potential research investigations that might be undertaken to enhance the design and development of a proficient chatbot system:

Undertake an extensive investigation to ascertain the distinct requirements, obstacles, and inclinations of NOUN pupils in their online learning encounter. Insights into the areas where a chatbot may provide the most value can be obtained by using methods like as surveys, interviews, or focus groups.

Examine the distinct features and capacities that would provide the most advantages for students enrolled at NOUN. This inquiry delves into the many categories of questions or activities that students often request help with, including but not limited to course selection, assignment submissions, accessing resources, and administrative processes. This research has the potential to ascertain the extent and characteristics of the chatbot system.

Examine the design components that lead to a favourable user experience with the chatbot. This encompasses the examination of the chatbot interface's usability, simplicity, and intuitiveness, with the assessment of its visual design and conversation flow. Gather input from students through user testing sessions or surveys in order to progressively enhance the design of the user interface.

This study aims to investigate the possible benefits and implications of integrating personalised suggestions and adaptive learning elements into the chatbot system. This study aims to examine the extent to which the chatbot may modify its replies and recommendations in accordance with the unique preferences, learning styles, and progress of individual

students. This has the potential to augment student engagement and provide a customised learning experience.

This research aims to conduct a comparative analysis to evaluate the efficacy of the chatbot system in enhancing the e-learning encounter at the National Open University of Nigeria (NOUN). This study aims to examine and contrast the levels of engagement, rates of satisfaction, and academic success between students who have access to a chatbot and those who do not. This has the potential to provide empirical data on the influence of the chatbot on student outcomes.

<h2>Welcome to the Centre of Technology Enhanced Learning </h2>
<p>The Centre was launched in Lagos, Nigeria to help students learn technology courses.

<p>We are pleased that all of these programmes have the approval of the National regulatory body, the National Universities Commission (NUC). In addition, the Centre will offer fourteen (14) short courses:</p>
<ul>
<li>Digital Literacy</li>
<li>Cyber Security</li>
<li>Entrepreneurship</li>
<li>Leadership and Project Management</li>
<li>Learning Technology</li>
<li>Programming</li>
<li>English Language for Non English Speakers</li>
```

```
    <li>Cloud Computing</li>
    <li>Block Chain</li>
    <li>Open Government Data</li>
    <li>Database Management</li>
    <li>Data Analysis</li>
    <li>Artificial Intelligence</li>
    </ul>
    </div>

DESIGN OF CHATBOT TO ENHANCE E-LEARNING EXPERIENCE OF STUDENTS OF NOUN

By

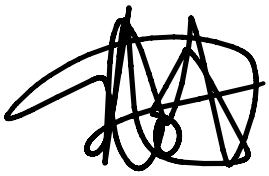
MORGRIDGE OLUWATOBI OPRAH

ACE21130002

A DISSERTATION SUBMITTED TO AFRICA CENTRE OF EXCELLENCE ON TECHNOLOGY ENHANCED LEARNING (ACETEL), IN PARTIAL FULFILLMENT OF THE REQUIREMENTS FOR THE AWARD OF MASTER OF SCIENCE (M.Sc.) DEGREE IN MANAGEMENT INFORMATION SYSTEMMS OF NATIONAL OPEN UNIVERSITY OF NIGERIA, ABUJA.

Declaration Page

I, Morgridge Oluwatobi Oprah hereby declare that the project work entitled Design of Chatbot to enhance e-Learning experience of Students of NOUN is a record of an original work done by me, as a result of my research effort carried out in ACETEL, National Open University of Nigeria under the supervision of Dr. Naeem Balogun and Dr. Emem Theophilus.



22/11/2023

Student's Signature & Date

CERTIFICATION

This is to certify that this study was carried out by ACE21130002 in ACETEL, National Open University of Nigeria, under my supervision.

Dedication:

I dedicate this work to God who is the author and finisher of all things.

Acknowledgements

As I conclude this significant chapter in my academic journey, I am filled with immense gratitude and appreciation for those who have been instrumental in my pursuit of this Master's degree.

First and foremost, I extend my deepest thanks to my family. Your unwavering support, encouragement, and belief in my abilities have been the bedrock of my strength and perseverance. To my parents, who have always been my guiding light, and to my siblings, whose constant love and cheer have brightened my days, I am eternally grateful.

I would like to express my sincere gratitude to my supervisors Dr Naeem Balogun and Dr Theophilus and my program coordinator, Dr. Juliana Ndunagu for their invaluable guidance, patience, and expertise. Your mentorship has not only shaped my academic work but has also profoundly influenced my personal growth and professional development. Your encouragement and high standards have pushed me to excel, and for that, I am truly thankful.

I am also grateful to my friends. Your companionship, understanding, and unwavering support have made this journey more enjoyable and memorable. To those who have offered their time, advice, and a listening ear during the most challenging periods, I am deeply appreciative.

Lastly, I acknowledge the contribution of my colleagues and the academic community at ACETEL, National Open University of Nigeria including our center director Prof Joktan, Mr Udochuku Nwakwo and so many others whose insights and perspectives have enriched my learning experience.

This thesis is not only a reflection of my hard work but also a testament to the collective support and inspiration provided by all of you. Thank you for being part of my journey.

ABSTRACT:

The purpose of this study is to enhance NOUN students' online learning experiences. The chatbot was built using Azure Cognitive Service for Language and Azure Bot Services, incorporating custom question answering capabilities. The study's objectives were to investigate the difficulties that students currently face in the online learning environment at NOUN, evaluate the use of chatbot technology to enhance the online learning experience, pinpoint design factors and specifications for a successful chatbot, and determine how much the implemented chatbot improves student e-learning experience. A questionnaire was designed and distributed to National Open University Students. A sample of 379 students was evaluated using SPSS, and a questionnaire was used to collect data for evaluation.

The data analysis revealed significant results for the research hypotheses. The relationship between the current challenges faced by students and their learning outcomes at NOUN was found to be significant, emphasizing the impact of technical issues and limited access to resources. The application of chatbot technology was also found to significantly improve the e-learning experience, aligning with the notion of personalized learning experiences and tailored support.

In conclusion, the study highlighted the significance of design considerations and requirements in developing an effective chatbot, emphasizing the importance of integrating Natural Language Processing (NLP) technologies and seamless integration into existing infrastructure.

CHAPTER ONE

Introduction

1.1 BACKGROUND OF THE STUDY

Over the past few years, e-learning has emerged as a crucial component of education and training, providing opportunities for customized learning, accessibility, and flexibility. One of

the obstacles encountered by e-learning platforms pertains to the absence of prompt and interactive assistance for learners (Maatuk et al.,2022). Chatbots are a technological innovation that may be effectively used inside this situation. A chatbot is an exemplification of software empowered by artificial intelligence (AI) that can mimic human speech and provide prompt assistance. The implementation of a tailored chatbot designed for the explicit objective of e-learning has the potential to revolutionize the way learners engage with online educational programmes. By using artificial intelligence (AI) and natural language processing (NLP) techniques, a chatbot may provide personalized assistance, prompt feedback, and insightful ideas, therefore enhancing the overall e-learning experience.

According to research conducted by Nuria (2019), a chatbot refers to a software program powered by artificial intelligence (AI) that enables conversation via voice or text. This technology has the potential to enhance language learning. Intelligence chatbots are advanced software or systems that demonstrate the capability to participate in conversational discussions with users across a wide array of topics. Artificial intelligence chatbots has the capacity to serve as effective instructors within the academic setting by offering educational materials, fostering discussions, and providing constructive feedback to learners, among other functionalities.

AI chatbots have the potential to function as an adjunct or assistive instrument for human teachers in some circumstances, since they may provide pupils with timely answers to their queries and offer education round the clock. According to Kleopatra et al., (2022), this strategy is deemed to be more practical and economical compared to exclusive dependence on human teachers.

The rapid progress in computing and information processing techniques has greatly accelerated the research and use of artificial intelligence (AI). This has allowed computers to do tasks by imitating intelligent human behaviours, such as reference, analysis, and decision-making (Duan et al., 2019). According to Roos (2018), there is a rapid and widespread expansion of the use of artificial intelligence (AI) in the domain of education. According to Okonkwo and Ade-Ibijola (2020), the use of Chatbot systems has become prevalent in the field of education as a means of delivering instructional content. Clarizia et al., (2018) argue that the use of this technology offers significant benefits in fostering educational outcomes within a scholarly environment.

The incorporation of chatbots in the realm of education has the potential to bring about a transformative shift in the educational domain. This is due to their ability to engage learners, customise learning experiences, assist educators, provide comprehensive insights into learner behaviour, and foster a more personalised and immersive learning environment for students (Gonda et al., 2018; Cunningham-Nelson et al., 2019; Bezverhny et al., 2020; Villegas-Ch et al., 2020; Kuhail et al., 2022b). Gonda et al., (2018) argue that the incorporation of educational agents facilitates the provision of individualised and timely feedback to students via conversational exchanges, as well as assists them in navigating virtual environments with assistance. According to Colace et al., (2018), there is an increasing trend in the use of chatbots into e-learning platforms to augment the learning experience of students. The integration of mobile learning into several e-learning environments, including learning management systems, social network platforms, and digital learning platforms, has been highlighted by Wollny et al., (2021) and Troussas et al., (2022). Durall and Kapros (2020) as well as Okonkwo and Ade-Ibijola (2021) assert that chatbots possess the capacity to expeditiously provide students with a diverse array of academic resources. These resources encompass course materials, practise assessments, grading criteria, essential deadlines, academic guidance, campus orientation, and study aids. According to Cunningham-Nelson et al., (2019), intelligent systems have the capability to augment student involvement and ease the workload of educators, thereby allowing them to dedicate more time to curriculum design and assessment.

Extensive research has been conducted on the use of chatbot technology within the educational environment. Numerous research papers have examined diverse uses of chatbots, including the areas of addressing student concerns, improving the comprehension of computer programming principles, assessing student performance, and providing administrative services. (Clarizia et al., 2018; Sinha et al., 2020) have been cited in this context. Furthermore, as the demand for education continues to rise, higher education institutions are under increasing pressure to accommodate a larger influx of students. The expansion of the student population is accompanied by a significant decrease in the provision of academic assistance for pupils. This tendency has been shown to result in less-than-ideal information acquisition and subsequently lead to higher rates of termination of academic endeavours. Although there are many theoretical solutions available for this issue, the majority of them are impractical to implement due to budgetary and administrative constraints (Hien et al., 2018). In order to tackle this substantial endeavour, educators at the post-secondary level have begun the integration of chatbots into their instructional practices

as pedagogical agents. The integration of chatbots in expansive educational settings has the potential to enhance individualised student learning through the provision of timely responses to student queries, the provision of a wide range of learning resources for instructional purposes, the reinforcement of course content and materials, and the collection of feedback on instructional courses. The proposition in question has been put out by prominent researchers, namely Winkler and Söllner (2018) and Almurtadha (2019).
Despite the existence of several studies that have showcased the potential advantages of chatbot applications in improving the teaching and learning process, the incorporation of these applications in higher education environments is still in its early stages. Therefore, it is crucial to conduct thorough research and investigation, specifically focusing on the ways in which students acquire knowledge through these intelligent systems. The primary objective of this research is to investigate the effects of integrating a FAQ chatbot system into an e-learning platform on the improvement of motivation and learning techniques among students enrolled at the National Open University of Nigeria (NOUN).

1.2 STATEMENT OF THE PROBLEM

The National Open University of Nigeria (NOUN) is an institution of remote learning that provides educational opportunities to a wide range of students who are unable to physically attend traditional institutions. While online learning offers flexibility, it sometimes lacks the dynamic and personalised experience often seen in conventional classroom environments. To address this issue, the implementation of a customised FAQ chatbot on NOUN's e-learning platform has the potential to promote student engagement, provide personalised support, and improve the overall e-learning experience.

The absence of interactive elements within the existing e-learning system at NOUN is a significant obstacle for students in accessing timely feedback, personalised assistance, and engaging in meaningful discussions. While conventional classroom environments provide students the chance to interact with both instructors and peers, the existing e-learning system at NOUN mostly operates in an asynchronous manner, lacking instant support. As a result, students may have challenges in understanding complex concepts, feel a feeling of isolation, and demonstrate a decrease in their motivation to gain information.

Additionally, the e-learning system currently in place at NOUN relies mostly on static resources, such as textual course materials and pre-recorded lectures. Often, these materials

demonstrate a lack of engagement and fail to appropriately address the distinct learning needs of people. Therefore, students may have challenges in understanding and remembering the curriculum content, leading to reduced academic performance and lower overall educational outcomes.

Therefore, the development of a tailored chatbot for the e-learning platform of NOUN is imperative. The chatbot should be equipped with the capacity to provide immediate support, provide personalised assessments, facilitate engaging discussions, and adapt to the specific learning techniques and preferences of the user. The incorporation of a chatbot into NOUN's e-learning platform has the potential to enhance student involvement, optimise educational achievements, and foster a more dynamic and personalised e-learning experience for its students.

1.2.1 RESEARCH QUESTIONS:

- What are the current challenges faced by students in the e-learning environment at NOUN?
- How can chatbot technology be applied to improve the e-learning experience at NOUN?
- What are the design considerations and requirements for developing an effective chatbot for NOUN?
- To what extent does the implemented chatbot enhance student engagement and satisfaction?

1.3 AIM OF THE STUDY

The main aim of this study is to design a chatbot to enhance e-learning experience of NOUN students.

1.4 SPECIFIC OBJECTIVES

I. Investigate the existing e-learning environment at NOUN and identify the challenges faced by students.
II. Design and develop a chatbot system tailored to the specific needs of NOUN students.
III. Evaluate the effectiveness of the chatbot in enhancing student engagement and satisfaction.

IV. Explore the potential benefits and applications of chatbot technology in improving the e-learning experience.

1.5 SCOPE OF THE STUDY

The scope of the study " Design of Chatbot to enhance e-Learning experience of Students of NOUN" focuses on the development and implementation of a chatbot specifically designed for enhancing the e-learning experience at the National Open University of Nigeria (NOUN).

The study aims to assess the effectiveness of the chatbot in improving student engagement, providing personalized support, and enhancing overall learning outcomes. The National Open University of Nigeria serves as a case study institution to investigate the practical application of the chatbot in a real educational setting. The study would cover the following aspects:

Literature Review: A comprehensive review of existing literature on chatbots, e-learning, and related technologies to establish a theoretical foundation for the research.

Identification of Requirements: Analysis of the e-learning environment at NOUN to identify specific requirements and challenges that can be addressed through the implementation of a chatbot.

Design and Development: Creation of a chatbot system tailored to the e-learning needs of NOUN, considering factors such as user interface design, natural language processing capabilities, and integration with existing e-learning platforms.

Implementation and Testing: Deployment of the chatbot system in a controlled environment to evaluate its functionality, usability, and performance. Testing should involve real users, such as students and instructors, to gather feedback and assess the effectiveness of the chatbot.

Evaluation and Analysis: Analysis of the collected data to evaluate the impact of the chatbot on the e-learning experience, including factors like student engagement, learning outcomes, and user satisfaction. Comparison of the results with the pre-chatbot implementation phase should be conducted to determine the improvements achieved.

1.6 SIGNIFICANCE OF THE STUDY:

Personalized Learning: Chatbots can provide personalized learning experiences by understanding individual learner's needs and preferences. They can adapt the content, pace,

and style of instruction based on the learner's progress, enabling a more customized approach to education.

24/7 Availability: Chatbots can be available round the clock, providing learners with instant access to information and assistance. Students can ask questions and seek guidance at any time, which enhances their learning experience and reduces waiting time for responses.

Instant Feedback and Assessment: Chatbots can offer immediate feedback on assignments, quizzes, or assessments. This prompt feedback helps learners identify their strengths and weaknesses, allowing them to focus on areas that require improvement. It also provides a sense of progress and accomplishment.

Active Learning and Engagement: Chatbots can engage learners through interactive conversations, simulations, and gamification elements. By creating a conversational and interactive environment, chatbots promote active learning, keeping learners engaged and motivated throughout the e-learning process.

Scalability and Cost-Effectiveness: Chatbots can handle a large number of learners simultaneously, making them scalable for massive open online courses (MOOCs) or large-scale e-learning platforms. They can provide personalized support to each learner without the need for additional human resources, making e-learning more cost-effective.

Continuous Learning Support: Chatbots can serve as virtual tutors, providing ongoing support to learners even after the completion of a course. They can offer additional resources, recommend further learning materials, and answer questions related to the topics covered in the course, helping learners reinforce their knowledge.

Data Collection and Analysis: Chatbots can collect data on learners' interactions, preferences, and learning patterns. This data can be analyzed to gain insights into individual and collective learning behaviors, allowing instructors to identify areas for improvement in the e-learning experience and make data-driven instructional decisions.

Accessibility and Inclusivity: Chatbots can improve accessibility for learners with disabilities or special needs by providing alternative modes of interaction, such as voice input or text-to-speech capabilities. They can also offer multilingual support, making e-learning more inclusive and accommodating diverse learner populations.

Overall, the study on the use of chatbots in e-learning has the potential to enhance the learning experience by personalizing instruction, providing instant feedback, promoting engagement, and improving accessibility while offering scalability and cost-effectiveness for educational institutions and platforms.

1.7 DEFINITION OF TERMS

Chatbot: A chatbot is an artificial intelligence (AI) program designed to simulate human conversation. It can engage in interactive and natural language-based communication with users, typically through text-based interfaces. In the context of e-learning, chatbots are utilized to provide support, guidance, and personalized interactions with learners.

E-learning: E-learning, or electronic learning, refers to the use of digital technologies and online platforms for educational purposes. It involves the delivery of educational content, resources, and interactions via digital media, allowing learners to access and engage with educational materials remotely.

Personalized Learning: Personalized learning refers to an instructional approach that tailors educational content, pace, and methods to meet the individual needs, interests, and preferences of learners. In the context of e-learning, chatbots can be used to provide personalized learning experiences by adapting the learning process to each learner's specific requirements.

Instant Feedback: Instant feedback refers to providing learners with immediate responses or assessments regarding their performance, progress, or understanding of the content. In the context of e-learning and chatbots, instant feedback can be given through automated responses to questions, quizzes, or assignments, allowing learners to receive feedback without delays.

Gamification: Gamification involves incorporating game elements, mechanics, and design principles into non-game contexts, such as education, to enhance engagement and motivation. In e-learning, chatbots can utilize gamification techniques to make the learning experience more interactive, enjoyable, and immersive for learners.

Massive Open Online Courses (MOOCs): MOOCs are online courses designed for large-scale participation and open access. They provide learners with the opportunity to access course materials, participate in discussions, and interact with instructors and peers from

around the world. Chatbots can be employed in MOOCs to support learners by aiding, answering questions, and facilitating engagement.

Accessibility: Accessibility in e-learning refers to designing and providing educational materials and platforms that are accessible to individuals with disabilities or special needs. When using chatbots to improve the e-learning experience, accessibility considerations may involve ensuring compatibility with assistive technologies, providing alternative modes of interaction (such as voice input), and offering accessible content formats.

Data Analysis: Data analysis involves the examination, interpretation, and extraction of insights from collected data. In the context of using chatbots to improve e-learning, data analysis can be performed on the interactions between learners and chatbots to gain insights into learning patterns, preferences, and performance. These insights can inform instructional decisions, personalized recommendations, and overall improvements in the e-learning experience.

1.8 ORGANIZATION OF THE THESIS

Chapter One of the research work provides an overview of e-learning and the challenges it faces in terms of personalization, engagement, and accessibility. It identifies the specific issues or gaps in the e-learning experience that chatbots can address. It also clearly states the objective of the study and the purpose of using chatbots in e-learning.

Chapter Two provides a review of relevant literature and studies on e-learning, chatbots, and their potential impact on educational experiences. It discusses the benefits, challenges, and best practices related to the use of chatbots in e-learning. It also analyzes existing frameworks or models for integrating chatbots into e-learning environment.

Chapter Three of the study describes the research methodology employed, such as quantitative, qualitative, or mixed methods. It explains the data collection methods, tools, and instruments utilized (e.g., surveys, interviews, and observations). It provides details on the sample population and any ethical considerations.

Implementation and Design of a Chatbot System: The Chapter will explain the design principles and considerations for developing a chatbot system for e-learning. It discusses the architecture, technologies, and platforms used in implementing the chatbot system; it

describes the functionalities and features of the chatbot system that enhance the e-learning experience.

Chapter Four of the study will present and analyze the data collected from learners' interactions with the chatbot system. It evaluates the effectiveness of the chatbot in improving the e-learning experience based on metrics such as engagement, satisfaction, and learning outcomes.

Chapter Five will focus on discussion of the implications of the study's findings on the use of chatbots in e-learning. It addresses the strengths, limitations, and potential future research directions. Provide recommendations for educators, instructional designers, and policymakers regarding the integration of chatbots into e-learning environments.

CHAPTER TWO

REVIEW OF RELATED LITERATURE

2.0 INTRODUCTION

The review of the related literature based on the variables of the research objectives were presented in this chapter.

2.1 THEORETICAL FRAMEWORK

2.1.1 TECHNOLOGY ACCEPTANCE MODEL

The Technology Acceptance Model (TAM) is widely used and applicable in several fields, including education. Throughout the passage of time, other researchers have proposed various expansions to this paradigm. Nevertheless, the Technology Acceptance Model (TAM) is often regarded as a suitable framework for assessing the extent to which people accept technology. Presently, the prevailing computer-mediated environment has a significant impact on communication across many contexts. In the given circumstances, chatbots have become a software programme that facilitates and maintains textual conversations with users in many fields of study. According to Chocarro et al., (2021), chatbots provide many benefits in terms of convenience and cost-effectiveness, making them a beneficial tool. The Technology Acceptance Model (TAM) is a theoretical framework often used in the field of education to assess the acceptance of new technological innovations with the goal of improving the overall quality of education. Therefore, the model assumes a crucial function in influencing the execution and dissemination of educational materials within the educational system. The incorporation of innovative technology has emerged as a key focus for several educational institutions, with specific attention paid to the use of software applications such as chatbots. The purpose of these tools is to improve the educational experience for students throughout their academic journey. Recent studies have shown that the use of the Technology Acceptance Model (TAM) has yielded improvements in the academic performance of pupils. The availability of chatbots has a significant impact on their performance, and the Technology Acceptance Model (TAM) provides a framework for facilitating efficient access to these resources (Adamopoulou & Moussiades, 2020b). The relationship between the Technology Acceptance Model (TAM) and chatbots in an educational setting generally supports the improvement of education quality via the enhancement of pedagogical and learning methods.

2.1.2 UNIFIED THEORY OF ACCEPTANCE AND USE OF TECHNOLOGY (UTAUT)

The Technology Acceptance Model (TAM) is widely used across several areas, including the field of education, due to its widespread applicability and relevance. Throughout the passage of time, other researchers have proposed various additions to this model. Nevertheless, the Technology Acceptance Model (TAM) is often regarded as a suitable framework for assessing the extent to which people accept technology. Presently, the major factor shaping communication in many contexts is the pervasive impact of computer-mediated platforms. In the given circumstances, chatbots have become a software program that facilitates and maintains textual conversations with users in many fields of study. According to Chocarro et al., (2021), chatbots provide inherent benefits in terms of ease and cost-effectiveness, thereby establishing their worth as a valued tool. The Technology Acceptance Model (TAM) is a theoretical framework often used in the field of education to assess the implementation of new technological innovations with the objective of improving the overall quality of education. Therefore, the model assumes a crucial function in influencing the execution and provision of educational resources within the educational system. The incorporation of innovative technology has emerged as a key focus for several educational institutions, placing notable importance on the use of software applications like chatbots. These tools have been specifically developed to augment the educational experience and improve the overall quality of instruction that students receive along their academic journey. Recent studies have shown that the use of the Technology Acceptance Model (TAM) has yielded improvements in the academic performance of pupils. The availability of chatbots has a significant impact on their performance, and the Technology Acceptance Model (TAM) facilitates convenient access to these resources (Adamopoulou & Moussiades, 2020b). The relationship between the Technology Acceptance Model (TAM) and chatbots in an educational setting generally supports the improvement of education quality via the enhancement of pedagogical and learning methods.

Performance expectancy: Venkatesh et al., (2003) propose that the concept of "perceived usefulness" refers to an individual's perception of the system's capacity to enhance work performance. The notion of performance expectancy is informed by multiple theoretical frameworks, such as the Technology Acceptance Model (TAM), TAM2, Combined TAM,

the Theory of Planned Behaviour (CTAMTPB), the Motivational Model (MM), the Model of PC Utilisation (MPCU), Innovation Diffusion Theory (IDT), and Social Cognitive Theory (SCT). These theories include factors like perceived utility, extrinsic motivation, job fit, relative advantage, and outcome expectations. Zhou, Lu, and Wang (2010) and Venkatesh, Thong, and Xu (2016) have shown that this specific feature has a strong correlation with use intention and possesses considerable importance in both voluntary and required settings.

Effort expectancy Venkatesh et al., (2003) define usability as the degree of convenience associated with the use of a certain technology. Effort Expectancy is a composite construct that is formed from the perceived ease of use and complexity, as proposed by the Technology Acceptance Model (TAM), the Mobile Payment Continuance Usage (MPCU) model, and the Innovation Diffusion Theory (IDT). The concepts and measuring scales of these theoretical frameworks demonstrate a certain level of resemblance. Gupta, Dasgupta, and Gupta (2008), as well as Chauhan and Jaiswal (2016), have argued that the continued use of technology leads to a diminishing relevance of its influence on the construct.

Social Influence Venkatesh et al., (2003) posit that the concept of perceived behavioural control refers to an individual's subjective view of the level of expectation from important people regarding their utilisation of a new technology. The notion of social impact exhibits similarities to the subjective norms, social variables, and image constructs used in several theoretical frameworks, including the Theory of Reasoned Action (TRA), Technology Acceptance Model 2 (TAM2), Theory of Planned Behaviour (TPB), Combined TAM-TPB (CTAMTPB), Model of PC Utilisation (MPCU), and Innovation Diffusion Theory (IDT). The commonality between these two perspectives is their mutual focus on the notion that people's actions are shaped by their sense of how they are seen by others. Venkatesh et al., (2003) assert that the effect of social factors is significant in contexts where the use of technology is obligatory. Venkatesh and Davis (2000) propose that humans may engage with technology in a compulsory manner due to adherence to regulatory obligations rather than being driven by personal inclinations. The discovery may provide an explanation for the varying effects of the construct in question, as shown in later research that has validated the model (Zhou, Lu, & Wang, 2010; Chauhan & Jaiswal, 2016).

Facilitating conditions Venkatesh et al., (2003) define the concept of perceived infrastructure as the subjective view held by a person about the degree to which an organisation's technological infrastructure is accessible and capable of supporting the utilisation of a certain system. The concept of facilitating conditions is developed from a combination of constructs, including compatibility, perceived behavioural control, and facilitating circumstances. These constructs have been included in many theoretical frameworks, including the Theory of Planned Behaviour (TPB), the Combined Theory of Acceptance and Use of Technology (CTAMTPB), the Model of Personal Computer Use (MPCU), and the Innovation Diffusion Theory (IDT). There is a positive correlation between the existence of enabling circumstances and the desire to use. However, this correlation becomes less significant after the first use. Venkatesh et al., (2003) provides a model that posits a significant and immediate influence of enabling factors on use behaviour.

The influence of predictors on intention is determined by the moderating effects of age, gender, experience, and voluntariness of usage. The influence of all four predictors is dependent on the age variable. The associations among effort expectation, performance expectancy, and social influence are subject to gender-based influences. The effect of effort anticipation, social influence, and enabling factors on an individual's behaviour is contingent upon their degree of experience. Venkatesh et al., (2003) posit that the effect of social factors on an individual's desire to engage in a certain behaviour is contingent upon the degree of voluntariness associated with that behaviour.

The Unified Theory of Acceptance and Use of Technology (UTAUT) has made significant contributions to the extant scholarly literature. This research provides an empirical analysis of technology acceptability by conducting a comparative investigation of important ideas in the area. These theories are recognised for their tendency to provide varied or inadequate perspectives on the subject topic. Venkatesh et al., (2003) argue that UTAUT has superior predictive capacity when compared to other models, such as Davis (1993) and Sheppard, Hartwick, and Warshaw (1988), that examine the adoption of technology. The elements postulated in the Unified Theory of Acceptance and Utilisation of Technology (UTAUT) together explain 70% of the variability seen in individuals' desire to utilise technology. Venkatesh et al., (2003) assert that the adoption of technology is a multifaceted phenomenon that is contingent upon the interplay of social and demographic variables with conceptions.

This underscores the complex and multifaceted nature of the process since it is dependent on factors such as an individual's age, gender, and level of experience.

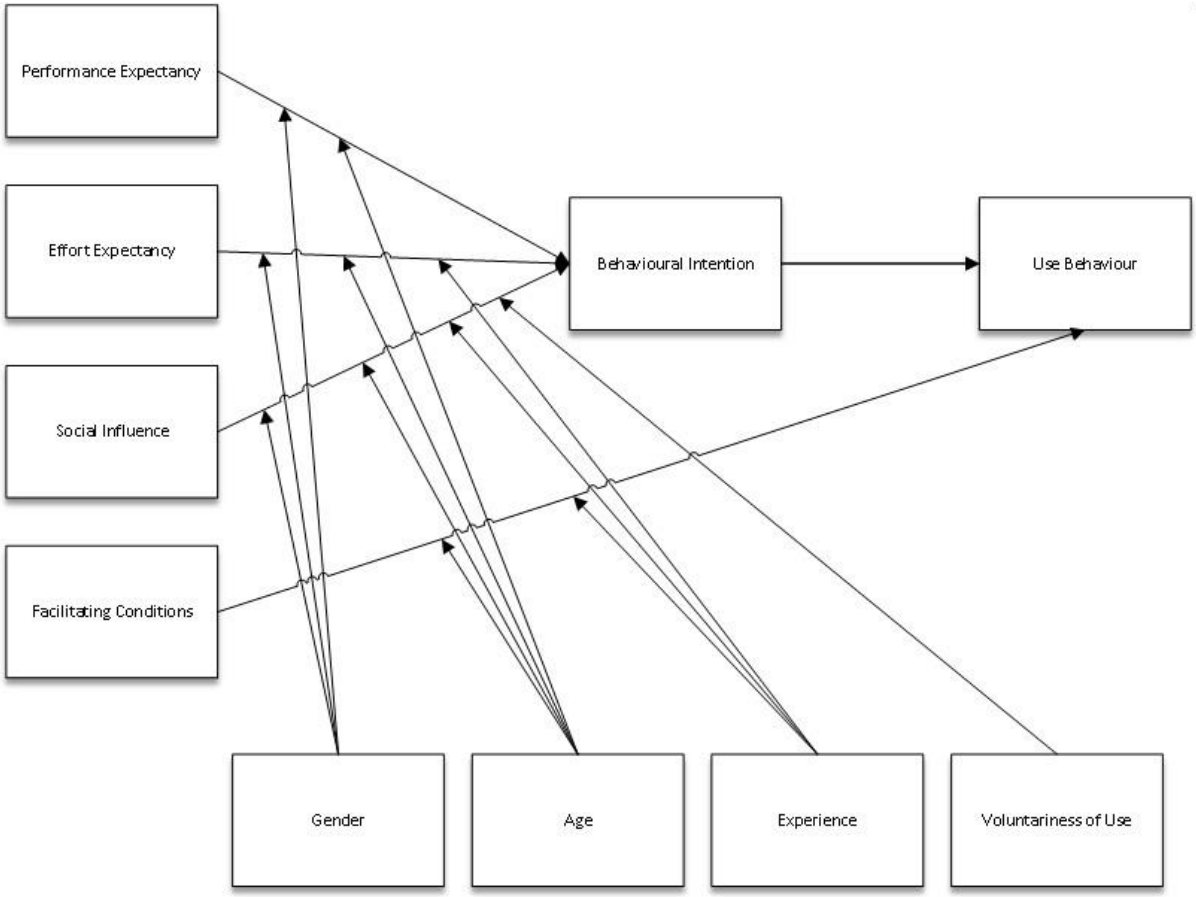

Figure 1: The UTAUT model Source: Venkatesh et al., (2003)

The modifications implemented on the model were derived from four main techniques, specifically: a) contextual adjustments to the model; b) changes to endogenous variables; c) incorporation of attitudinal antecedents; and d) examination of various moderating factors. The original research endeavour broadened the scope of the model's use to include emerging technologies, including enterprise systems and e-health systems. Furthermore, the study focused on user categories that had not been previously addressed, namely healthcare professionals, and thoroughly examined the model in several geographical and cultural settings, including India and China. According to the studies conducted by Chang et al., (2007), Yi et al., (2006), and Gupta, Dasgupta, and Gupta (2008), it has been found that... In

their study, Casey and Wilson-Evered (2012) extended the existing model by including online-specific factors, such as trust and personal web innovativeness, to assess its effectiveness in predicting the adoption of web tools. The Unified Theory of Acceptance and Use of Technology (UTAUT) has been further developed by the inclusion of new endogenous factors (Sun, Bhattacherjee, & Ma, 2009), such as satisfaction and continuous intention to use (Maillet, Mathieu, & Sicotte, 2015). The third study stream investigated other aspects that have an impact on use and behavioural intention. These factors include task-technology compatibility and individual personality characteristics (Zhou, Lu, & Wang, 2010; Wang, 2005). Numerous scholarly investigations have extended the scope of the Unified Theory of Acceptance and Use of Technology (UTAUT) by including further contextual and moderating variables. The characteristics included in this analysis comprise, but are not limited to, culture, ethnicity, religion, job status, language, income, education level, and geographical location (Im, Hong, & Kang, 2011; Al-Gahtani, Hubona, & Wang, 2007; Riffai, Grant, & Edgar, 2012).

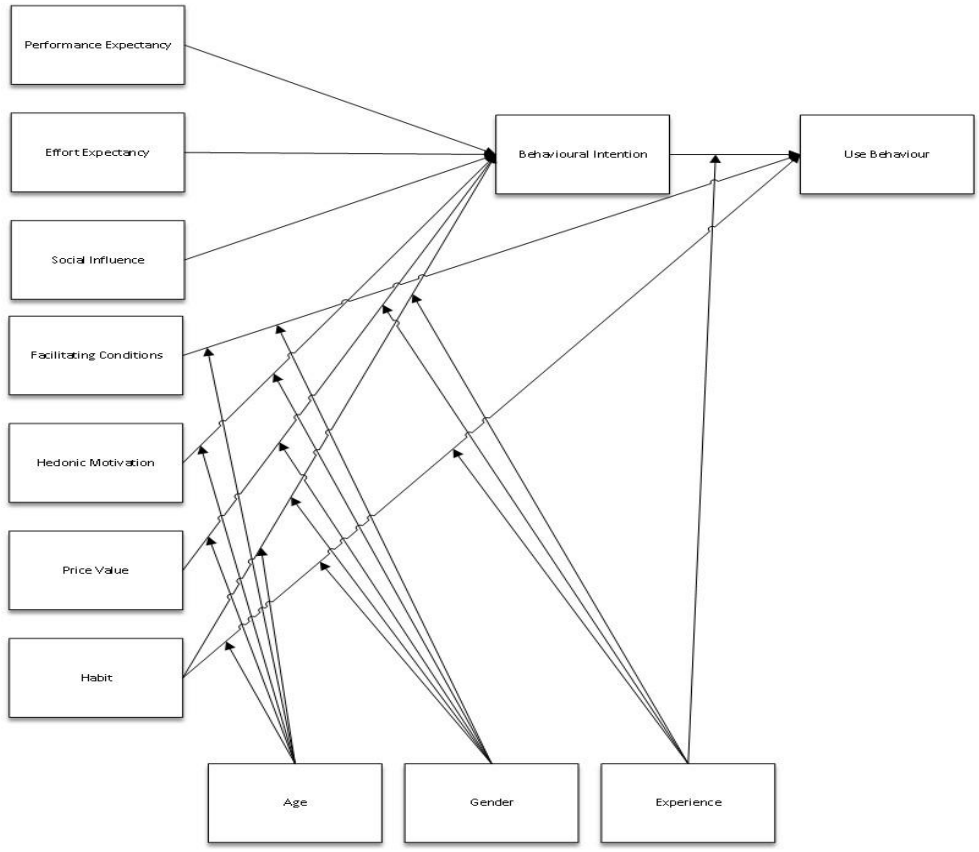

Figure 2: DOI theory (Rogers, 2003)

In summary, the Unified Theory of Acceptance and Use of Technology (UTAUT) is a conceptual framework that enhances the understanding of humans' intentions and behaviours

around technology adoption. Although UTAUT was originally designed to understand the acceptability of technology in a general context, it has the capacity to be used in several domains, including the area of e-learning. The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) within the realm of e-learning might manifest in several ways.

Exploring the concept of user acceptance: The use of the Unified Theory of Acceptance and Use of Technology (UTAUT) may be utilised to analyse the many aspects that influence the acceptance and utilisation of electronic learning platforms or systems. The paradigm encompasses four essential elements, namely performance expectation, effort expectancy, social influence, and enabling factors. By assessing these characteristics, researchers may get useful insights about users' tendencies regarding the acceptance and usage of e-learning systems.

The process of determining the influential factors The Unified Theory of Acceptance and Use of Technology (UTAUT) functions as a framework for identifying the key factors that influence the adoption of e-learning. Performance expectation refers to the perceived effectiveness of e-learning in achieving educational goals, whereas effort expectancy relates to the user friendliness and perceived ease of use of the e-learning system. By comprehending these characteristics, educators and designers may focus on enhancing the factors that promote user adoption.

Customising e-learning interventions: The Unified Theory of Acceptance and Use of Technology (UTAUT) may be used as a theoretical framework to guide the design and implementation of strategies targeted at promoting the adoption of e-learning. By discerning the key determinants that influence user behaviour, educators and e-learning providers may develop efficacious tactics to surmount possible barriers and enhance the catalysts for adoption. If it is established that social influence is a significant element, it might be advantageous to include collaborative capabilities or peer interactions into the e-learning platform in order to enhance social engagement.

Evaluating User Experience: The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) may serve as a method for evaluating user happiness and experience pertaining to electronic learning (e-learning) systems. By gaining an understanding of the factors that influence user acceptance, organisations may evaluate and improve the effectiveness, usability, and overall user satisfaction of their electronic learning platforms.

The data has the capacity to guide improvements in the system and provide a positive educational experience for the users.

The UTAUT framework has the capacity to anticipate the likelihood of technology uptake and use. The assessment of the level of acceptance and utilisation of e-learning technologies by intended users within organisations may be conducted via the evaluation of the four components of the Unified Theory of Acceptance and Use of Technology (UTAUT). The capacity to anticipate forthcoming results may possess considerable importance within the realms of decision-making, resource allocation, and planning.

The Unified Theory of Adoption and Use of Technology (UTAUT) provides a comprehensive theoretical framework for understanding and predicting people's adoption and use of technology, including e-learning platforms. The application of the Unified Theory of Acceptance and Use of Technology (UTAUT) in the context of electronic learning (e-learning) has the potential to provide valuable insights pertaining to the creation of effective interventions, enhancement of user experience, and promotion of the adoption of e-learning technologies.

2.1.3 DIFFUSION OF INNOVATION THEORY (DOI):

The notion of DOI is concerned with the dissemination of new ideas and technology within society, including the techniques, reasons, and speed at which they spread. The phenomenon functions on both individual and communal scales. According to Oliveira and Martins (2011), the word DOI refers to a theoretical concept that elucidates the processes, rationales, and temporal dynamics of DOI. The notion of distributing innovation was first formulated by researchers, but it has now gained widespread acceptance. Rogers (1995) posits that the acceptance of innovations follows a five-stage process. The steps include the acquisition or recognition of information, the process of persuasion, the act of making a choice, the execution of such a decision, and the subsequent confirmation or adoption. Before embracing a novel concept, a person or entity often engages in a sequential progression consisting of five distinct stages. Rogers (1995) posits the existence of inventive features that may be used to examine the factors contributing to the success or failure of ideas in attaining general adoption inside organisations. This objective may be achieved within the context of the adoption phase. The Diffusion of Innovation Theory, developed by Everett Rogers, is a well-recognised framework in the field of social sciences. Theory provides a comprehensive understanding of the mechanisms via which new ideas, goods, and technologies are spread

and adopted by people and groups within different communities. This theory has a wide range of applicability across several academic fields. The idea is often used to grasp and predict the integration of new technology. This assists technology developers and innovators in identifying potential barriers and enablers of adoption. Organisations may proficiently direct their marketing tactics and customise their product offers to cater to the distinct requirements and preferences of each demographic segment. Understanding the concept of diffusion of innovation helps augment an organisation's capacity to effectively launch and advertise novel goods or services in the marketplace. Through the process of tailoring their marketing tactics, firms have the ability to increase the probability of effectively introducing and implementing their technical products or services.

2.2 REVIEW OF RELEVANT LITERATURE:

2.2.1 OVERVIEW OF THE CHATBOT:

The emergence of Artificial Intelligence in Education (AIEd), shortened as AIEd, may be historically attributed to the 1970s, as shown by Kay's (2015) scholarly investigation. Academic scholars focus their efforts on the examination, development, and evaluation of computer software to improve the educational process. The process of setting long-term objectives encompasses several key steps, including gathering feedback from learners, assessing their proficiency, identifying areas for improvement, tailoring instruction to meet the needs of individuals or groups, and ultimately employing artificial intelligence techniques to explore and improve pedagogical theories. The incorporation of scientific inquiry in artificial intelligence (AI) and its intersection with the disciplines of psychology and pedagogy in the realm of education is an essential component of the function fulfilled by AIEd. The first schematic shown in Figure 1 showcases two separate methodologies for the incorporation of artificial intelligence into the field of education. The given text does not provide enough information to be rewritten in an academic manner. Please provide AIEd, short for Artificial Intelligence in Education, pertains to the amalgamation of Artificial Intelligence (AI) with the field of Educational Research. The field under consideration is a unique and multidisciplinary sector that delineates its own aims and bounds, effectively connecting the realms of Artificial Intelligence and Education (Sjödén, 2015). The field of artificial intelligence (AI) generally centres on the study of machine learning and the advancement of intelligence that resembles that of humans. Conversely, education mostly

concentrates on the cultivation of human intellect and the augmentation of one's capacity for learning. The insights provided by AIEd help to reduce this gap by offering approaches that enable more effective and insightful interactions with people, ultimately improving educational outcomes. The domain of Artificial Intelligence in Education (AIEd) has shown a strong inclination towards investigating the capabilities of AI techniques in creating educational resources that can adeptly tailor learning experiences to accommodate the distinct needs of individual learners (Conati, Porayska-Pomsta, & Mavrikis, 2018). The examination of the effectiveness of an AIEd system in comparison to that of an individual human tutor has been a topic of significant scholarly interest since the advent of computers (VanLehn, 2011). Chatbots are a prominent and extensively used manifestation of artificial intelligence. The concept of a chatbot gained significant attention after Alan Turing's introduction of the Turing test, sometimes referred to as the "Can machines think?" test, in 1950 (Turing, 2009, pp. 23–65). The year 1966 saw the emergence of Eliza, a chatbot that is generally seen as a groundbreaking innovation. Eliza operated as a psychotherapist, using a unique approach to engaging users by reacting to their input with probing inquiries (Weizenbaum, 1966). In 1995, Wallace (2009) documented that Alice was acknowledged as the first Chatbot to achieve the designation of a "Human Computer." The advent of modern technology has given rise to the development of chatbots such as SmarterChild (Moln'ar & Szuts, 2018), Apple Siri, Amazon Alexa, IBM Watson, Microsoft Cortana, and Google Assistant (Reis et al., 2018). The rapid progress of chatbot technology since 2016 has led to the development of many types of chatbot systems designed specifically for industrial use. According to Nayyar (2019), there has been a notable increase in the use of Chatbot apps on digital platforms to enhance the educational experience of students. Currently, there are several disparate definitions associated with the notion of a chatbot. As stated by Ciechanowski et al., (2019), a chatbot refers to a software programme that replicates and understands human conversation, allowing users to interact with electronic devices in a way that simulates speaking with a genuine human being. According to existing research, the proposed method might potentially manifest as either a collaborative learning conversation (Ruan et al., 2019) or an automated system specifically developed to provide replies to human inquiries (Rosruen & Samanchuen, 2018). According to the research conducted by Clarizia et al., (2018), a Chatbot may be defined as an intelligent agent that exhibits the capacity to participate in conversations with students, offering them precise and reliable solutions to a variety of inquiries. Chatbots are often seen as interactive or chat agents that provide prompt replies to users, as highlighted by Okonkwo and Ade-Ibijola (2020) and Smutny and Schreiberova (2020). The use of chatbots

has become more common in improving learner engagement in the modern technology environment, where communication and other activities mostly depend on digital platforms. The Chatbot system exhibits the capability to operate as a mobile web application, thereby enabling the facilitation of the learning process. Dsouza et al., (2019) believe that the use of Chatbot technology in the field of education serves to augment students' interactive capabilities and streamline automated teaching methodologies. Ondas et al., (2019) reported that there is an observed improvement in connection and efficiency during interactions. Cunningham-Nelson et al., (2019) argue that online learning environments have the capacity to provide a focused, personalised, and results-oriented method of teaching, a characteristic that is much valued by modern educational establishments.

2.2.2 CHATBOT SYSTEM ARCHITECTURE

According to previous research conducted by Colace (2017) and Clarizia et al., (2018), an electronic chatbot system has been implemented utilizing the website http://ailearning.edu.vn. The website's architecture is depicted in Figure 1, while the chatbot's interaction is illustrated in Figures 2 and 3.

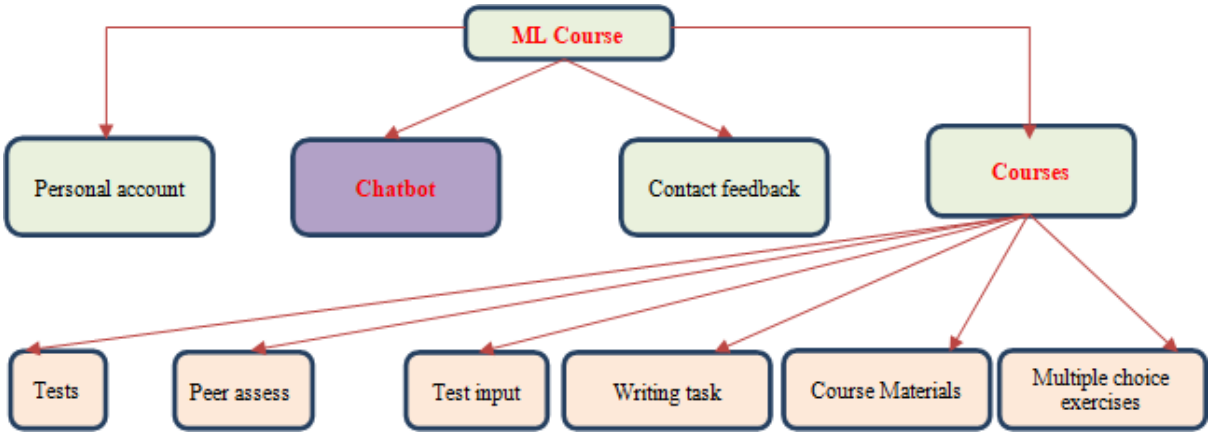

Figure 3: Structure diagram of the UML Course system

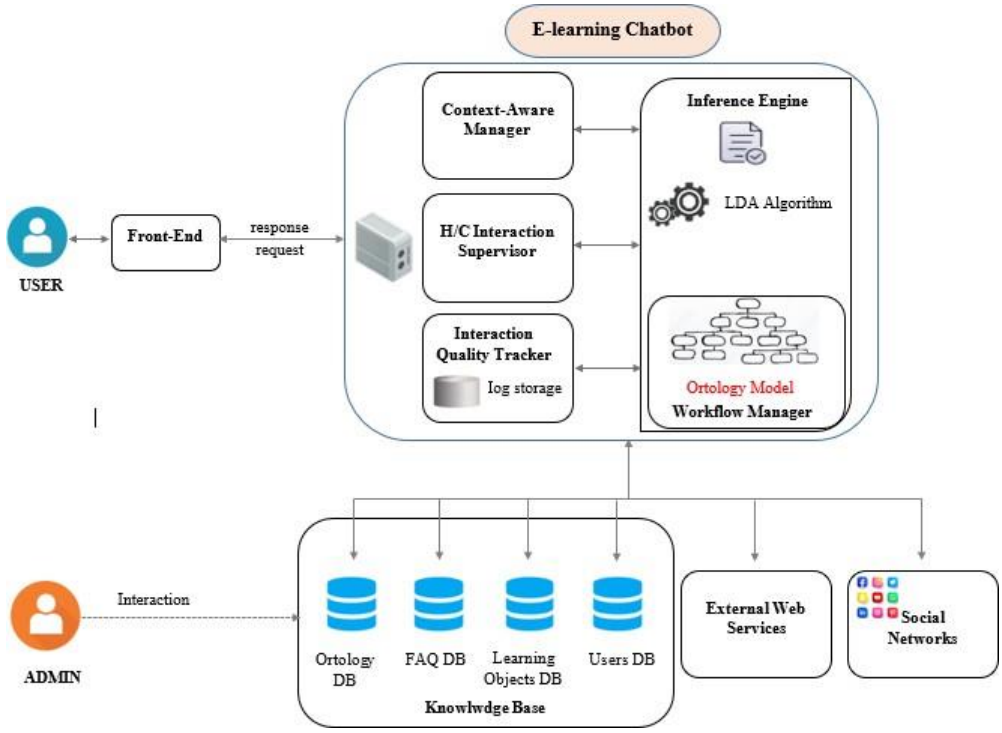

Figure 4: E - learning interactive system architecture (Colace, 2018)

2.2.3 CHATBOT FRAMEWORKS

There are many platforms that make it quick and easy to build chatbots, like Google's Dialogflow, Microsoft's Azure Bot Framework, Facebook's Bots for Messenger, and Amazon's Alexa. In addition, there are many other powerful Chatbot platforms that are widely used, such as ManyChat, Chatfuel, Converable, and GupShup. S. Raj (2019), outlining the following chatbot frameworks:

- **Language Studio is** a cloud-based framework provided by Microsoft that allows a simple Q&A chatbot to be developed based on FAQs, URLs, and structured
- **Dialogflow**, a popular cloud-based framework provided by Google, is very easy to use and allows integration with multiple platforms.
- **Rasa NLU and Core** are open-source frameworks provided for the Python development environment.

2.2.4 BENEFITS OF CHATBOTS APPLICATION IN EDUCATION

Winkler and Soellner (2018) propose that the incorporation of Chatbots within the realm of education has promise for augmenting students' academic performance and general contentment. A multitude of scholarly investigations have substantiated the effectiveness of Chatbots within the realm of education. The research, conducted by Duall and Kapros (2020), Hien et al., (2018), Mor et al., (2018), Ndukwe et al., (2019), Okonkwo and Ade-Ibijola (2020), Ranoliya et al., (2017), and Ureta and Rivera (2018), have together examined the effective implementation of Chatbots inside educational environments.

The use of chatbots has several advantages in educational environments, including cost reduction, faster response times, improved engagement, innovative learning, and higher efficiency (Llic & Markovic, 2016; Bii, 2013). The reason for this perception is because chatbots are often seen as a safe and user-friendly platform for engaging in online conversation (Cameron et al., 2017). Furthermore, chatbots have the capability to operate as a round-the-clock support service, effectively handling often asked issues, and giving users access to educational resources (Garcia-Brustenga et al., 2018; Winkler & Söllner, 2018). Consequently, this enhances overall productivity. Moreover, students are provided with the opportunity to use chatbots as a tool for enhancing their memory and facilitating the retrieval, review, and preservation of previously acquired information. Chatbots have the capacity to provide timely and efficient assistance or facilitate the acquisition of information, all the while fostering curiosity and engagement via their interactive, friendly, and interpersonal characteristics. Students regard chatbots as a novel and unique phenomena.

The integration of chatbot technology might be considered a noteworthy progression in the domain of digital education. In the domain of quality, they are generally recognised as the most innovative approach for bridging the gap between technology and education. Chatbots provide an engaging educational experience for students, similar to a personalised engagement with a teacher. Bots play a crucial role in augmenting the abilities of individual pupils via the monitoring of their development and analysis of their learning behaviours. Numerous scholarly publications have presented empirical evidence showcasing the diverse benefits that Chatbots may provide to the field of education. The aforementioned advantages encompass:

2.2.4.1 The process of combining and merging different pieces of content into a cohesive and unified whole is referred to as content integration.

The teacher has the capacity to upload relevant information, including specified subjects, assignment timelines, and other resources, into a digital platform that is easily available to authorised students. Chatbots has the capacity to assist in the distribution of relevant information to pupils. Educators could inform pupils about upcoming school events that may capture their attention, including sports tournaments, instructional seminars, and a range of extracurricular activities. According to the literature, several studies have examined the use of Chatbots in the realm of education as a means of facilitating the integration of academic content, thereby providing students with convenient access to it regardless of their location or time constraints (Akcora et al., 2018, pp. 14–19; Wu et al., 2020).

2.2.4.2 Rapid retrieval

Clarizia et al., (2018) assert that the integration of chatbots into educational settings has the potential to improve the effectiveness and outcomes of student learning. This assertion is further corroborated by the findings of Wu et al., (2020), who highlight the ability of chatbots to provide quick and convenient access to instructional material. On the other hand, the Chatbot has the capacity to function as a mechanism for social learning. According to Hussain et al., (2018), various student populations has the capacity to provide distinct perspectives and valuable insights on a particular subject matter. Additionally, chatbots may be tailored to cater to individualised issues.

2.2.4.3: The Role of Motivation and Interaction in Learning

In present-day culture, there is a growing trend among students to favour the use of smartphones for accessing and examining digital information, rather than relying on conventional textbooks or printed materials. Recent research done by Chen et al., (2020) and Pham et al., (2018) has shown that the implementation of interactive systems, such as Chatbots, has the potential to enhance student motivation and cultivate an environment that is favourable to learning and enjoyable. The use of a conversational agent as an instructional tool not only engenders irritation among students but also allows a more efficient learning of information. The dimensions of a class at a university may have influence on the pedagogical methodology used by an instructor, as well as the dynamics of student engagement within the classroom setting. Lee (2009) asserts that smaller class sizes provide more opportunities for interaction and cultivate favourable rapport between students and teachers. On the other hand, learners attach importance to their communication needs and see it as a vital component in improving their academic performance and satisfaction (Dennen et al., 2007). The efficacy of Chatbot technology in facilitating educational support has been shown by empirical investigations undertaken by Moln'ar and Szuts (2018), Adamopoulou and Moussiades (2020), and Albayrak et al., (2018), which have provided evidence of its positive impact on student engagement. Furthermore, it is plausible that they may play a substantial role in motivating students to actively participate in academic activities by consistently delivering alerts and cues.

2.2.4.4 Provision of Immediate Assistance

One of the key advantages of using Chatbots in the field of education is its notable benefit. Alias et al., (2019) assert that the incorporation of Chatbots in the realm of education enables expeditious settlement of queries presented by researchers and students. According to the study conducted by Okonkwo and Ade-Ibijola (2020), it was found that Chatbots possess the capability to provide prompt support to learners, facilitating the optimisation of various tasks such as homework submission, email communication (Molnar & Szuts, 2018; Murad et al., 2019), and timely resolution of inquiries (Sreelakshmi et al., 2019).

The functionality of enabling numerous users to use a system or platform is now accessible.

Another significant advantage of integrating Chatbot technology in the field of education is its ability to provide simultaneous access by several users to the system. This suggests that the Chatbot has the capability to support seamless conversation among several students from various geographical areas, allowing them to acquire the necessary knowledge. Rooein (2019) argues that Chatbots have the capacity to effectively handle several enquiries at once, resulting in time efficiency for users. Wu et al., (2020) argue that the use of Chatbot technology in the field of education offers a notable benefit in terms of enabling simultaneous access by numerous users.

2.2.4.5 The provision of personalized assistance

According to Cunningham-NNelson et al., (2019) and Su, M. H. et al., (2017), the incorporation of Chatbot technology is a prominent approach within the realm of education, serving to enhance and support a personalised learning experience. The implementation of the Chatbot system as a mobile application may function as a tool to enhance the learning process. Chatbots possess the capacity to expeditiously provide learners with consistent information, including details pertaining to syllabi, exercises for interactive question-and-answer sessions, and supplementary resources. Based on academic literature, the use of chatbot technology has promise in providing students with a personalised learning curriculum and fostering a more engaging educational environment (Benotti et al., 2017; Cunningham-NNelson et al., 2019). The deployment of such technologies has the capability to augment student involvement and assistance while concurrently mitigating the administrative load on instructional personnel. As a result, this facilitates educators to focus on the construction of curricula and engage in research pursuits.

2.2.5 IMPACT OF CHATBOTS ON EDUCATION

Based on current academic research, the integration of chatbots in the field of education has not been extensively implemented. The reason for this is that the technology of chatbots is still in its early phases of development in the field of education. As a result, users are required to conduct experiments to determine the benefits and limits of chatbots in this particular context (Beckingham, 2019). Nevertheless, previous scholarly works suggest that the use of chatbots in the field of education is expected to result in significant improvements in both academic achievements and the overall welfare of students (Winkler & Soellner, 2018). The efficacy of incorporating chatbots into educational settings has been demonstrated in a limited number of previously published research. The creation of 'Jill Watson', a chatbot

developed at the University of Georgia, exemplifies the use of the IBM Watson platform in the management of forum posts from students participating in a computer science course (McFarland, 2016). The major aim of the initiative was to augment student participation in the course, and the results suggest that this objective was successfully accomplished. The potential use of chatbots in large-scale educational environments, such as universities or massive open online courses (MOOCs), shows promise in overcoming the inadequacy of personalised support provided by academic institutions. The insufficiency mentioned is a significant determinant that contributes to the retention rates of fewer than 10% seen in Massive Open Online Courses (MOOCs). Sinha et al., (2019) argue that chatbots has the capacity to provide individualised learning assistance while requiring less financial and organisational resources from educators.

According to study data, there is a growing trend in the use of chatbots by users. According to the results of the research, a significant majority, over 80% of the participants, had previous familiarity with the use of a chatbot. According to the results of the poll, it was observed that almost 75% of those who had not before interacted with a chatbot belonged to the age group of 45 years or above. According to recent research, there is evidence to suggest that younger individuals are more likely to have a greater propensity for adopting new technological innovations, such as chatbots. These automated conversational agents have garnered considerable attention in current discussions (Almansor & Hussain, 2019).

In the study conducted by Silvervarg et al., (2014), it was shown that chatbots has the capacity to work as educational guides and assistants, providing a range of capabilities including information retrieval, knowledge distribution, and improved understanding. When appropriately engineered, chatbot technology has the potential to provide continuous access to instructional materials throughout the whole of the learning process. Educators may use student enquiries as a method for collecting data, expanding their knowledge base, and augmenting their expertise by using chatbot technology. The process entails the chatbot actively seeking out inquiries and augmenting its knowledge repository with supplementary responses. Based on the research conducted by Shawar and Atwell (2007) as well as Shawar (2005), a considerable fraction of students exhibit a preference for chatbot technology in comparison to search and sort-based tools. This preference stems from the chatbot's capacity to provide quick replies, as opposed to guiding users towards supplementary sources for further investigation.

Winkler and Söllner (2018) argue that chatbots have significant educational potential and may positively impact student learning and satisfaction via the provision of personalised learning support. Although there is a substantial amount of existing literature discussing the successful implementation of chatbots (Dutta, 2017; Huang, Lee, Kwon, & Kim, 2017; Kerly, Hall, & Bull, 2007), there is a scarcity of research investigating their potential in the field of education (Kowalski et al., 2011). The utilisation of chatbots in the realm of education is presently constrained as a result of insufficient comprehensive investigation on this matter (Baker, 2016; Goos et al., 1998; Bayan & Atwel, 2007; Gimeno, 2008; Wang, 2008; Torma, 2011; Govindasamy, 2014; Osodo, Indoshi, & Ongati, 2010). Numerous studies have been undertaken in the Thai context to examine the application of chatbots for diverse objectives, such as the provision of customer service (Santirattanaphakdi, 2018), system guidance (Bungodchai, 2017), performance agency (Lerdsahapan, 2015), and disease diagnosis (Mokarat, Unchai, & Marpae, 2016). Despite the considerable promise of chatbot technology as a digital learning tool for delivering tailored learning assistance, the subject of education still lacks a substantial body of study in this area. Therefore, further research is necessary to expand the understanding of chatbot technology.

2.2.6 CHATBOT INTERFACE AND EFFICIENT E-LEARNING PLATFORM

The combination of a chatbot interface with a skilled e-learning platform may effectively enhance the learning experience for students by promoting cohesion and efficacy. The following passage provides an overview of how these elements might function as interdependent constituents.

This research focuses on investigating the design and implementation of a chatbot interface specifically designed for course navigation purposes. The chatbot has the capacity to serve as an intermediate tool, aiding students in their utilisation of the e-learning platform. The chatbot has been specifically developed to provide students with relevant information on courses, modules, assignments, deadlines, and other queries linked to the platform. The chatbot's capacity to provide timely and relevant responses may lead to efficiency gains for students who would otherwise need to manually search for information.

The integration of data analytics and machine learning algorithms by the chatbot enables the delivery of tailored learning suggestions inside the electronic learning (e-learning) platform. The chatbot has the capability to provide recommendations for courses, modules, or resources that align with the educational goals, academic performance, and personal preferences of students. This characteristic enhances the effective exploration of relevant content by pupils, hence enhancing their educational experience.

Within the framework of an electronic learning environment, it is possible that students may find it necessary to seek immediate assistance and elucidation during the duration of their academic pursuits. The chatbot has the capacity to provide expeditious aid to users by promptly responding to their enquiries in real-time. The educational content has the capability to address often asked questions, provide clarifications, and aid learners in comprehending complex concepts. The availability of immediate help ensures that students may get support as needed, therefore enhancing the overall learning experience.

The use of chatbot technology into the analytics system of an e-learning platform helps students in acquiring significant information pertaining to their development and performance. The chatbot offers students the opportunity to access information pertaining to their completion status, assessment results, and general development. The availability of immediate feedback allows students to effectively track their academic progress and make educated choices about their study habits and areas in need of improvement.

The chatbot has the capacity to disseminate instructional material to students via the e-learning platform, thereby streamlining the process of delivering information and alerts. The system has the capacity to transmit relevant articles, videos, or instructional materials that correspond with the students' interests or academic prerequisites. In addition, the chatbot has the capacity to provide messages or reminders on upcoming deadlines, recent course offers, or important announcements, ensuring that students are adequately informed and engaged.

The incorporation of a chatbot facilitates the implementation of interactive learning experiences within the framework of an electronic learning environment. The chatbot interface has the capacity to provide users with quizzes, flashcards, or interactive simulations. The use of gamification strategies promotes an engaging and collaborative educational environment, improves information retention, and boosts student engagement in the digital learning context.

The integration of a chatbot into the e-learning platform might enhance the delivery of timely and advantageous feedback to students pertaining to their assignments or examinations. The system has the capacity to provide automated evaluation, identify areas in need of improvement, and suggest resources or strategies for enhancing performance. The quick feedback loop enables students to effectively assess their progress and adjust their learning tactics appropriately.

The incorporation of a chatbot interface into a capable e-learning platform has the potential to enhance accessibility, personalisation, and assistance within the domain of online education for educational institutions. The chatbot serves as a digital assistant, providing direction to students, making personalised ideas, delivering educational resources, and facilitating interactive pedagogical experiences. The incorporation of these components augments students' academic achievement and cultivates an engaging and effective digital learning environment.

2.2.7 CHATBOT PLATFORM AND EFFICIENT STUDENTS FEEDBACK

In the study conducted by Hwang et al., (2021), it was shown that virtual education offers many benefits, such as more flexibility and enhanced connection and interaction between instructors and students, regardless of their geographical location or time limitations. There are other modalities of online feedback strategies that may be provided to students, presenting similar benefits, and allowing them to engage with the material at their own speed. Various types of feedback are used in academic settings to give students with guidance on their

written projects. These forms include electronic feedback methods such as monitor changes in Microsoft Word, concise remarks sent by email, spoken feedback delivered during online meetings, screen-captured video feedback, and computer-generated automated feedback. According to Cheng and Li (2020), Liu et al., (2021), and Ware and Warschauer (2006), According to recent research conducted by Alharbi and Al-Hoorie (2020) as well as Liu et al., (2021), in virtual learning environments where students maintain anonymity and abstain from revealing their facial characteristics, there is a tendency for them to freely express their opinions to their peers and receive constructive and advantageous feedback.

Butler and Winne (1995) assert that feedback is a vital component of the educational process as it allows students to identify areas in need of development and assess their academic progress. According to Sadler (1989), it is said that feedback that is useful should provide accurate information on a learning activity or process. This feedback should address the gap between the intended and actual understanding of the subject matter or the development of abilities. By engaging in the feedback process, students strive to enhance their weak or insufficient knowledge and abilities that might hinder their academic progress. Numerous academic investigations have shown that the receipt of constructive criticism may yield beneficial outcomes in the realm of learning (Hattie & Timperley, 2007; Nicol & Macfarlane-Dick, 2006; Parikh et al., 2001). According to the research conducted by Black and Wiliam (1998), which included more than 250 studies on feedback, it was shown that feedback had a significant impact on enhancing student learning outcomes as well as their overall happiness. In their research, Henderson et al., (2019) undertook an examination of seven case studies using a range of methodologies including theme analysis, case comparison, and reliability verification. The objective of the research was to ascertain the key factors that enable the delivery of constructive criticism. The current situation highlights the need of carefully designing feedback systems, which may be categorised into three specific groups: capacity, projects, and culture. The significance of feedback in online learning settings is heightened due to the lack of face-to-face interaction among participants, as emphasised by Ypsilandis (2002). According to Nicol and Macfarlane-Dick (2006), in online environments when instructors and students are physically distant or have different schedules, it is crucial for instructors to provide high-quality feedback to support students' learning and motivation. Tseng and Tsai (2007) conducted a research which found that the provision of reinforcing feedback may have a substantial positive impact on the quality of students' projects, especially when considering online peer evaluation. The considerable size of the student body

in online learning environments might be a challenge for educators in providing meaningful and sufficient feedback to students. The improvement of feedback practises has been the subject of discussion by Belcadhi (2016), Gulwani et al., (2014), and Marin et al., (2017), who have offered several automated solutions for this purpose. The act of delivering feedback via online platforms has inherent obstacles. In a study conducted by Alharbi and Al-Hoorie (2020), it was shown that technological issues, such as the abrupt cessation of digital platforms, might provide challenges for second language learners in engaging with feedback. Ware and Warschauer (2006) argue that people may have difficulties in effectively organising and handling lengthy online discussion threads and responses, posing a challenging undertaking. According to Cheng and Li (2020), there may be instances when individuals exhibit a lack of familiarity with some forms of online feedback, such as video feedback. Furthermore, there is a prevalent expectation among students to get timely and frequent digital assessments pertaining to their academic advancement or tasks (Mory, 2004). Nevertheless, the availability of such evaluations may not be regularly guaranteed.

2.2.8 CHATBOT PLATFORM AND STUDENTS INTERACTIONS

The use of chatbots, which are conversational educational agents, has been seen in the area of education since the early 1970s (Laurillard, 2013). Pedagogical agents, sometimes known as intelligent tutoring systems, are digital entities that provide instructional support to persons in educational environments (Seel, 2011). Conversational Pedagogical Agents (CPAs) may be identified as a specific subgroup within the category of pedagogical agents. Gulz et al., (2011) assert that these entities possess the capacity to engage students in discourse-driven exchanges by using artificial intelligence. The consideration of several components, such as social, emotional, cognitive, and pedagogical characteristics, is crucial in the creation of computer-based learning environments, as emphasised by Gulz et al., (2011) and King (2002).

Conversational agents can use many forms of communication to interact with pupils, such as spoken communication (Wik & Hjalmarsson, 2009), textual communication (Chaudhuri et al., 2009), and nonverbal communication (Wik & Hjalmarsson, 2009; Ruttkay & Pelachaud, 2006). According to Dehn and Van Mulken (2000), there exists variation in the visual depiction of agents, which may be characterised by criteria such as their likeness to people or cartoons, the degree of animation, and the amount of dimensionality. In recent years, there has been a development of conversational agents that serve several educational purposes, such as acting as tutors, coaches, and learning companions (Haake & Gulz, 2009).

Furthermore, conversational agents have been utilised to meet various educational needs, such as answering inquiries (Feng et al., 2006), offering guidance (Heffernan & Croteau, 2004; VanLehn et al., 2007), and facilitating the acquisition of language skills (Heffernan & Croteau, 2004; VanLehn et al., 2007).

Within the domain of student engagement, chatbots have taken on several functions, such as teaching agents, peer agents, teachable agents, and motivating agents, as shown by the research conducted by Chhibber and Law (2019) and Baylor (2011). Based on the findings of Wambsganss et al., (2020) and Kulik & Fletcher (2016), it has been observed that teaching agents have the capability to do several duties that are conventionally fulfilled by human instructors. These jobs include the delivery of instructions, provision of examples, formulation of questions, and provision of fast feedback. In contrast, peer agents serve as educational companions for students, facilitating peer-to-peer interactions. The agent tasked with executing this strategy demonstrates a comparatively lesser degree of proficiency in comparison to the instructional agent. Nevertheless, peer agents possess the capacity to guide pupils along a trajectory of knowledge acquisition. It is a prevalent practise among students to engage in discussions with their peers in order to get definitions or seek more understanding on a certain subject matter. Peer agents have the ability to provide scaffolding for instructional dialogue among their peers.

Students have the ability to provide instructions to teachable agents, which in turn aids in facilitating a progressive learning experience. The approach used in this study entails the agent assuming the role of a beginner and actively seeking help from students in order to navigate through a learning trajectory. Baylor (2011) asserts that motivational agents play a role as companions to students, offering encouragement for good behaviour and learning, rather than directly contributing to the learning process.

According to Følstad et al., (2018), the interaction between chatbots and users may be categorised as either chatbot-driven or user-driven, based on the manner in which they engage with each other. Budiu (2018) asserts that chatbot interactions often adhere to premeditated and organised structures, following a linear format that encompasses a limited range of possible trajectories, which are dependent on the user's inputs. Chatbots of this kind are often created using if-else statements. The perception of a seamless communication experience occurs when the respondent's replies align with the conversational environment. However, complications develop when users deviate from the prescribed sequence of tasks.

User-initiated dialogues powered by artificial intelligence provide flexible chats, giving users the autonomy to pose diverse inquiries and diverge from the predefined script of the chatbot. Chatbots may be categorised into two distinct groups according on their user interaction patterns: one-way chatbots and two-way user-driven chatbots. Dutta (2017) asserts that chatbots that are user-driven use machine learning methodologies to interpret the user's input and then generate a response from a pre-existing repository of responses. On the other hand, chatbots that are led by the user and function in a bidirectional manner provide accurate replies by assembling individual words to cater to the user's needs (Winkler & Söllner, 2018).

Chatbots may be categorised into three distinct groups according on the kind of interaction they employ: text-based, voice-based, and embodied. Text-based agents allow users to participate in conversations by typing on a keyboard, while voice-based agents promote communication via the use of a microphone. Brewer et al., (2018) found that voice-based chatbots provide enhanced accessibility for older persons and those with particular requirements. In terms of their implementation, chatbots possess the capacity to be integrated across a range of messaging platforms, such as Telegram, Facebook Messenger, and Slack (Car et al., 2020). Furthermore, they may be used as independent web or mobile apps or incorporated into intelligent devices like as televisions.

2.2.9 EFFECTIVENESS OF THE CHATBOT IN IMPROVING STUDENTS E-LEARNING EXPERIENCE

Chatbots are digital agents that may act as virtual assistants by fielding questions and providing answers, as described by Clarizia et al., (2018). A text-based chatbot has been created by many authors (Salas-Pico & Yang, 2022; Topal et al., 2021). This chatbot runs in accordance with a pre-programmed set of rules, allowing it to respond to user enquiries. The term "artificial intelligence" (AI) is used to describe computer systems or computers that can learn and improve without human input (Angelov et al., 2021). In recent years, researchers have focused on chatbots (Salas-Pico & Yang, 2022; Topal et al., 2021). They have the ability to quickly analyse inquiries and provide answers (Angelov et al., 2021). Several examples of chatbots are presented in the literature, such as the Frequently Asked Questions chatbot (Han & Lee, 2022; Ranoliya et al., 2017), ELIZA, a pioneering Natural Language Processing software that emulated human-machine communication (Natale, 2019), and colMOOC, a conversational virtual agent designed to foster learners' engagement in massive open online courses (Tegos et al., 2019).

Okonkwo and Ade-Ibijola's (2020) research shows that most chatbots at universities are designed to aid educators. Mendoza et al., (2020) highlighted positive attitudes among students when they interacted with a chatbot. Several research (Hiremath et al., 2018; Mikic-Fonte et al., 2018; Pham et al., 2018; Sinha et al., 2020) have shown that students use chatbots to ask questions, get responses, and get individualised help.

Undergraduate students' learning results and motivation were examined in a research by Yin et al., (2021). Subjects were randomly allocated to either an experimental group that used a chatbot for assistance or a control group that did not. There was no discernible difference in performance levels between the two groups, according to the findings. A greater degree of motivation was indicated by students who used the chatbot compared to those who did not. In their research, Arruda et al., (2019) built a chatbot designed to help CS students model requirements with an end in mind. Students found the chatbot to be useful, and many showed interest in using it in the future, according to the study's findings. Students' mental health was improved by the use of chatbots and online courses in a research by Kamita et al., (2019). Chatbots were shown to have a higher chance of being effective in helping with self-learning, increasing motivation, and decreasing stress, as indicated by the research. The University of Georgia is responsible for the development and integration of the chatbot "Jill Watson" within a CS curriculum. Lipko (2016) found that the study's participants were more receptive than expected and wanted to use the chatbot in a variety of academic settings.

Harper et al., (2003), Sandu and Guide (2019), and Vlachopoulos and Makri (2021) all point out that asking questions in class is an important part of the learning process with the potential to raise students' grades. University students in Ghana seldom participate in class discussions with their professors. Essel et al., (2019) claim that as the number of pupils per teacher has increased, kids have received less individual attention from their teachers, contributing to the current problem. According to studies conducted by Oktaria (2021) and Soemantri (2021) and Verleger and Pembridge (2018), students are reluctant to ask questions because they are afraid of a negative response from their teachers. Some teachers respond to students' needs in this area by providing them with individualised help through instant messaging apps like WhatsApp and social media platforms like Facebook Messenger. However, a major challenge is that the teacher is not always available to respond to students' questions and provide timely, individualised grades. A lack of student-teacher engagement may have a negative impact on education. Students always demand accurate and quick feedback (Farhan et al., 2012), hence the problem of a delayed answer to their query is of

major relevance. When teachers are unable to provide enough feedback to students at all hours of the day or night, chatbots become more important (Yang & Evans, 2019). Research shows that using a chatbot may help students engage in conversational learning and review previously covered material (Göschlberger & Brandstetter, 2019; Jomah et al., 2016; Smith & Evans, 2018). As a result, this has been shown to improve adaptive learning (Fadhil & Villafiorita, 2017) and boost learning accomplishment and self-efficacy (Chang et al., 2021).

The use of chatbots may help overcome this obstacle by initiating conversations specific to each student's situation, leading to a more individualised learning experience (Hien et al., 2018; Howlett, 2017). According to Wang et al., (2021), a chatbot may act as an intermediary between a student and an instructor, allowing students to take charge of their own education and go through the material at their own speed. Verleger and Pembridge (2018) argue that chatbots may encourage students who are uncomfortable asking questions in a classroom to speak out. Students' overall learning experiences might be greatly improved with the use of chatbots in online classrooms. There is promise that a chatbot might improve the efficiency and effectiveness of online education for students.

Chatbots can provide students with tailored assistance and direction, paving the way for more personalised educational experiences. Based on each student's unique needs and learning style, teachers may tailor their recommendations, recommendations for educational resources, and assessments. Learners' engagement, motivation, and advancement towards their goals are all bolstered by individualised support.

Chatbots reduce students' dependency on human instructors and support staff by making information and assistance more quickly and easily accessible. The chatbot is prepared to respond promptly to queries, requests for clarification, and requests for help from students, allowing them to more easily interact with the system. By responding instantly to students' questions in real time, on-demand help improves the quality of the learning experience.

By providing a welcoming interface that accommodates various student preferences for learning, chatbots have the potential to improve access for students. The chatbot's ability to respond to both text and voice instructions makes it accessible to pupils with a wide range of skills. In addition, chatbots may give assistance in several languages, allowing pupils to use their native tongue while corresponding.

The use of chatbots may pave the way for the incorporation of gamification features into the e-learning experience. Teachers may make learning more engaging by including evaluations,

interesting assignments, and interactive activities. Adding gamification elements to chatbots might encourage student participation and improve their understanding of course material.

Analysing Student Performance and Adapting Instruction: Using chatbots, educators may keep tabs on their students' development and provide timely responses to their questions or concerns. They allow for the tracking of various educational KPIs including quizzes taken and courses finished. Students may use chatbots to evaluate their own performance and make adjustments to their approach to learning depending on the information they get about their strengths and weaknesses.

Chatbots may look at a student's preferences, interactions, and learning history to provide recommendations based on those factors. Articles, films, and courses that are relevant to the students' interests might be suggested by teachers as supplemental materials. This method may help students learn about previously unknown topics and broaden their horizons. The suggestions made here are meant to broaden and diversify the educational experience.

The use of chatbots in the classroom has the potential to increase student motivation and engagement by providing conversational engagements that mimic human-like interactions. By providing instantaneous and individualised feedback, chatbots have the ability to keep students engaged, answer their questions, and create a positive learning environment.

Chatbots provide for continuous assistance with schoolwork outside of regular classroom hours. The chatbot is available to students around the clock, not just during normal school hours. Learners may contact the chatbot whenever they need it, day or night, for help with everything from reviewing material to getting clarification to finding relevant resources.

By incorporating chatbots into the online classroom, schools may provide students with individualised help, instant support, engaging lessons, and consistent direction. The enhancements allow for a more interactive, inclusive, and effective electronic learning environment, which in turn leads to a better educational experience for students.

2.2.10 EFFECT OF THE CHATBOT ON STUDENTS' ACCESS TO INSTRUCTIONAL AND LEARNING RESOURCES

The use of a chatbot to broaden students' access to course materials might have far-reaching positive effects. Important ways in which chatbots are altering students' access to course materials include the following:

Better Availability and Convenience: Chatbots provide a simple and straightforward interface that helps students communicate with one another. Without having to wade through complicated systems or sift across several platforms, students may easily access learning materials and tools whenever and wherever they need them. Student involvement with required reading is facilitated by the increased convenience and heightened accessibility of resources.

By analysing students' interests, learning styles, and performance statistics, chatbots may provide highly customised suggestions for supplementary reading and viewing. The chatbot may tailor its suggestions to each individual learner, ensuring that they are relevant and useful to their individual needs and goals. Personalization has been shown to increase students' interest since it encourages them to explore a broader range of resources.

Chatbots can provide instant and relevant responses to student questions about course topics. The chatbot can quickly respond to students' inquiries and meet their requirements for clarification, additional resources, and suggestions. This method assures that students will get timely and relevant information while minimising the time and energy they spend completing individual resource searches.

Chatbots may be useful in the classroom since they might point students in the direction of relevant course resources that they would have missed otherwise. By recommending resources based on a student's interests and previous coursework, the chatbot increases their exposure to new ideas and concepts.

Chatbots may improve students' experience with learning management systems or digital libraries by providing better search and navigation tools. In response to questions on certain subjects or keywords, the chatbot may provide relevant materials or direct students to the appropriate parts. The optimised navigation mechanism makes it easier to find what you need in a large collection.

The conversational interface of chatbots might provide for engaging educational opportunities. For instance, schools may provide resources like quizzes, flashcards, or interactive simulations to help students learn and test their knowledge. By boosting user engagement and pleasure, the chatbot improves the quality of the learning experience.

Chatbots provide continuous guidance and support throughout the learning process. The chatbot is a reliable resource for students looking for information such as answers,

explanations, or suggested readings. Students benefit from a more streamlined and effective learning process when they are provided with constant advice since they know they have access to help whenever they need it. The chatbot's objective is to assist students fast and effectively while lessening the workload on the management system by responding to their questions. The presence of a chatbot will make student responses automatic and available around-the-clock. The NOUN chatbot will improve communication and raise student involvement. (Juliana et al, 2022)

Chatbots make educational and pedagogical resources more accessible to students by improving their ease of use, personalization, speed of feedback, and quality of direction. Institutions of higher learning may better support their students' learning goals and foster a more productive and engaging learning environment by taking advantage of these benefits.

2.3 REVIEW OF RELATED WORKS

Song et al., (2017) designed and built a chatbot platform to increase participation from graduate students in online courses. Based on the findings, graduate-level online courses are the optimal setting for real-time intellectual interactions between students and chatbot technology. Alkhoori et al., (2020) developed the UniBud chatbot to provide academic guidance to students using voice interaction platforms. Based on the results of the research, academic advisers are better suited to answer more difficult questions than UniBud, which has a limited ability to handle academic enquiries.

Troussas et al., (2017) developed the ALICE chatbot to aid in the acquisition of English by providing students with extensive learning and evaluation support. The study's results and the students' responses indicate that using a preexisting discourse to enhance mobile learning is a worthwhile strategy. The promise of this study, like that of other studies, is to provide students with ongoing learning support and instructional resources in a variety of media. The current inquiry is unique in that it incorporates both immediate and delayed types of support and assessment.

Lin and Chang's (2020) research project includes the development of a chatbot to help post-secondary students improve their writing. The study's participants benefited from the chatbot, the researchers discovered. The results show that having students converse with chatbots during class time boosts their drive to learn and makes the learning process easier to handle and more enjoyable for everyone involved. All of the aforementioned research has created and deployed chatbot systems, then assessed how well they helped K-12 pupils improve their language skills. The current study has the advantage of evaluating chatbot

systems' performance in a non-traditional language learning setting, focusing on graduate students.

Using the Facebook platform, Troussas et al., (2020) developed an intelligent educational software application they called i-LearnC#. Using a virtual trainer to create a specialised learning environment was meant to help students learn more effectively. The programme used a cluster analysis method to determine the most productive ways for pupils to work together. According to the results, college students who used the app benefited from it in terms of their education. The software served as an intelligent and adaptable learning environment, helping users learn more efficiently. The current study is similar to our continuing work in that both make use of the WhatsApp platform and a virtual tutoring approach to education. While other studies have focused solely on the impact of cognitive and metacognitive learning strategies on enhancing learning and the subsequent level of acceptance, this study departs from that trend by applying the Bashayer system within the realm of postgraduate education.

Troussas et al., (2022) presented a mobile learning-based educational application designed to improve students' cognitive capacities in elementary school via engaging in constructive learning activities and receiving positive reinforcement for their efforts. According to the results, the developed app successfully raised students' levels of critical thinking and intrinsic motivation. Our continuing study and the present inquiry are both concerned with measuring cognitive learning and intrinsic motivation. However, the current investigation is limited to a subset of graduate students. The focus of the research is not just on the development of students' cognitive skills, but also on the role that chatbots play in improving their metacognitive abilities as they learn.

A suggestion system using a chatbot to help students better self-regulate their learning was developed by Calle et al., (2021). In order to improve academic results, the system recommends how time, study sessions, resources, and activities should be allocated within a digital environment. The four studies all looked at the usefulness of chatbots for assisting college students with their schoolwork and social relations. This research stands out from the others by highlighting the need for investigating how chatbots affect real-world education. This research uses empirical approaches to evaluate chatbots' potential for boosting motivation and easing the use of cognitive and metacognitive processes in the classroom.

To help students improve their research skills, Vanichvasin (2020) investigated the creation of a chatbot as a digital learning aid. Thirty-six Thai college students took part in the

research. Multiple research tools were used in this study, including a chatbot, an assessment form, an efficacy questionnaire, and research tests, to determine the best course of action. Mean, standard deviation, content analysis, and a t-test were among the statistical approaches used to examine the data. Experts judged the chatbot to be highly applicable (= 4.67, SD = 0.08), and it was recommended that it be improved by adding research material and interactive learning, as shown by the study's findings. Fourteen students who were not part of the intended sample participated in a pilot research. With an average score of 4.43 and a standard deviation of 0.35, the survey revealed that students had a favourable impression of the chatbot. In order to make the chatbot more appealing, students suggested adding additional examples and pictures. With an average score of 4.37 and a standard deviation of 0.48, the chatbot was well-liked by its target audience of 36 Thai college students. Users saw chatbots as innovative, approachable, and fun to employ for learning reasons. The capacity to quickly access information and conduct targeted searches for specifics are two possible advantages. It is preferable to provide further information, such as relevant links, in response to queries that do not match specified keywords. It's also worth noting that the chatbot only provided replies when the user typed correctly. For this reason, a secondary option where consumers may choose from a list of questions or keywords should be included. The statistical analysis also showed that there was a statistically significant improvement between the pre- and post-test scores at the 0.05 level of significance. Positive learning results, such as enhanced individualised learning possibilities, have resulted from the use of chatbot technology in educational settings to improve students' research skills.

The adoption of chatbot technology in education

Evidenced by a growing body of work evaluating their potential in teaching and learning modalities, chatbot integration into e-learning settings has attracted considerable interest in recent years (Troussas et al., 2019; Smutny and Schreiberova, 2020). Lin and Chang (2020) argue that chatbots might play a variety of roles in the classroom, including those of conversational agents, support systems, and recommendation engines. According to the research conducted by Pérez-Marn (2021), chatbots may play many different functions in the lives of their human users, including those of counsellors, tutors, classmates, and even game masters. Use of innovative resources has the potential to improve students' motivation, knowledge retention, and overall performance in the classroom. Recent research from Lin and Mubarok (2021), Okonkwo and Ade-Ibijola (2021), Pérez-Marn (2021), and Fidan and Gencel (2022) all back up this idea. Colace et al., (2018) claim that using chatbots to assess student behaviour and track improvement may help students develop their abilities. Based on their reliability, accessibility, and constant availability, chatbots may provide exciting experiences for students, as pointed out by Sriwisathiyakun and Dhamanitayakul (2022). These features allow for dynamic dialogue between chatbots and students. Self-directed learning, heightened engagement in learning, goal-directedness, learning techniques, and academic accomplishment are all bolstered by the use of chatbot technology, which enables smooth and flexible interactions. Multiple investigations (Winkler and Söllner, 2018; Durall and Kapros, 2020; Pérez et al., 2020; Smutny and Schreiberova, 2020; Du et al., 2021; Haristiani and Rifai, 2021) corroborate this claim. In addition, some researchers have proposed that chatbots may help students improve their problem-solving and critical-thinking skills (Goda et al., 2014; Pérez-Marn, 2021; Cabrera et al., 2022). In addition, research suggests that chatbots can help students learn to be more independent and self-directed, reduce stress, and improve self-regulation in the classroom (Park et al., 2019; Calle et al., 2021; Cabrera et al., 2022).

There are a lot of upsides to using chatbot technology in education, and it has a lot of potential uses in the classroom. The use of a chatbot-based platform greatly improves the presentation of instructional information and resources by dividing lessons into manageable chunks and classifying homework assignments. According to the research of Pérez et al., (2020) and Haristiani and Rifai (2020), when students are given the freedom to choose their own learning goals, they are more likely to be successful (Pérez et al., 2020; Haristiani and Rifai, 2021). This upholds the principles of mastery-based education (Troussas et al., 2019) by giving learners control over their own learning in terms of

content, approach, and scheduling. giving a range of activities, encouraging students to actively participate in their own education, and giving constant feedback and guidance are all effective ways to help kids learn. In the end, this method helps students become fully proficient in the material. Chatbots' learning settings are rich with high-quality, time-saving instructional options. Without regard to time or location, chatbots make it possible for people to study together and share resources. Furthermore, they provide timely support for academic assignments from students located in the same physical location. Okonkwo and Ade-Ibijola (2021) and Troussas et al., (2022) indicate that the availability of learning modules that correspond with students' cognitive styles has been proven to improve the idea of personalised learning. Furthermore, chatbots enable mobile learning, which benefits from the advantages of continuous availability. These are seen as real-world examples of the pervasive learning notion, as stated by Heryandi (2020) and Sjöström and Dahlin (2020). When compared to other types of software, chatbots stand out due to their user-friendly design and conversational tone. These apps are also built for student-friendly platforms like Android and iOS, which are widely utilised in the classroom. In order to be useful, chatbots must be able to teach their users something by breaking down and presenting information in a way that facilitates learning and retention. Chatbots use novel methods to provide assessments, appraisals, and reactions that are in keeping with the physical characteristics of mobile devices, as stated by Troussas et al., (2020) and Wollny et al., (2021).

2.4 Summary/meta-analysis of Reviewed of Related Works

This chapter presents the results of the researcher's efforts to systematically evaluate the literature on the topic of chatbot creation for the enhancement of the e-learning experience, using the word as a case study. In this chapter, we looked at two theoretical frameworks: the Cognitive Theory of learning behaviour was an instinctive response to an experience, and the Bandura Social Learning Theory, which emphasises the necessity of monitoring and modelling the behaviours, attitudes, and emotional responses of students.

Using word as a case study, we conducted a comprehensive analysis of the literature on both the conceptual and practical aspects of designing a chatbot to enhance the e-learning experience. The majority of the research cited in the study were from inside Nigeria. Second, the ones done in Nigeria were not part of this investigation. The literature analyses also showed that the study's subvariables were examined separately, rather than in tandem. Other

studies' review samples were either too small or larger than the one used in the current research. This is when the researcher has identified a need for more empirical study to fill in the gaps in the current body of knowledge.

The purpose of this literature review is to synthesise the current research on chatbot design for improving the e-learning experience, with a particular emphasis on the NOUN as a case study. There is great potential for increased student engagement, individualised assistance, and efficient information acquisition via the use of chatbot technology in online education. This research intends to provide insights into the design of chatbots for e-learning that are unique to the setting of NOUN by methodically researching and analysing a variety of relevant works to discover common themes, best practises, and emerging trends.

CHAPTER THREE
RESEARCH METHODOLOGY

3.1 PREAMBLE

This chapter presents the research methodology employed in the study on the design of a chatbot to enhance the e-learning experience of students at the National Open University of Nigeria (NOUN). It includes the problem formulation, proposed solution, techniques used, tools utilized in the implementation, research design, validation techniques, performance evaluation parameters, and system architecture.

3.2 PROBLEM FORMULATION

This research aims to investigate the issue of insufficient personalised and interactive assistance inside conventional e-learning systems, which therefore results in diminished student engagement and unsatisfactory learning achievements. The chatbot need to adjust its functionality to accommodate the unique requirements and rate of progress of each individual student. According to Betts et al., (2020), it is recommended to conduct an analysis of user interactions, monitor progress, and provide customised feedback and assistance in response. The use of customization strategies may effectively target and mitigate individual challenges or misunderstandings that learners may encounter in relation to the subject matter, NOUN.

The chatbot should possess an interface that is user-friendly, characterised by its intuitive nature and ease of navigation. The system should use natural language processing skills in order to properly comprehend user inputs and provide relevant responses. According to Desk (2023), Furthermore, it is essential that the interface has an aesthetically pleasing design and is easily available on a multitude of devices or platforms that are often used for e-learning purposes. Through the consideration and integration of these fundamental elements, the design of the chatbot has the potential to significantly augment the e-learning encounter for students enrolled in NOUN, affording them an interactive and tailored instrument.

3.3 PROPOSED SOLUTIONS

The suggested approach is the creation of a customised chatbot designed exclusively for the e-learning platform at the National Open University of Nigeria (NOUN). The major objective of this chatbot is to provide individualised assistance to students, facilitating their access to educational materials and resources, resolving their inquiries, and eventually improving their overall experience with online learning.

Developing a chatbot with the aim of enhancing the e-learning encounter, using NOUN as a case study, necessitates a deliberate and strategic methodology. The process involves the consideration of several criteria, such as the requirements of the users, the desired learning outcomes, and the technical aspects of implementation. In order to do this, a number of recommended goals have been developed for the purpose of creating the chatbot.

First and foremost, the implementation of comprehensive user research is of utmost importance in order to ascertain and pinpoint the precise pain points and issues encountered by learners at the National Open University of Nigeria (NOUN). The process of collecting insights from individuals' experiences will facilitate the customization of the chatbot to meet their specific needs. Furthermore, it is important to get input from both students and administrators in order to have a comprehensive understanding of their expectations and requirements pertaining to the chatbot in question. According to Bezverhny, Dadteev, Barykin, and Klimov (2020), drawing insights from the experiences of others might be a useful learning opportunity.

The establishment of precise learning goals for the chatbot is of utmost importance. The goals should involve the provision of vital course information, fast response to inquiries, provision of study tools, and assistance with assignments, all in accordance with the curriculum and learning outcomes of NOUN students. Establishing a coherent and user-friendly conversational structure inside the chatbot is crucial in facilitating smooth navigation across diverse encounters. The seamless user experience provided by this organic flow will facilitate the interaction between students and other users, enabling them to effortlessly connect with the chatbot and get the desired information. The integration of the chatbot with NOUN's pre-existing Learning Management System (LMS) is a crucial measure aimed at augmenting its overall capabilities. Through this approach, students are able to experience uninterrupted accessibility to educational resources, check their academic performance records, and get timely notifications, all within a cohesive and integrated framework.

The consideration of technical concerns should not be disregarded. The seamless user experience is contingent upon the criticality of guaranteeing interoperability and data synchronisation between the chatbot and the Learning Management System (LMS). In addition, the ongoing enhancement of the chatbot is vital for optimising its efficacy. Consistently gathering input from users facilitates the identification of areas that may be improved and refined. The optimisation of the chatbot's performance and accuracy may be

enhanced by the analysis of user interactions and use patterns, as supported by the research conducted by Dersch, Renkl, and Eitel (2022). Through careful consideration of these goals, the implementation of the chatbot may be implemented in a deliberate manner, tailored to meet the unique requirements of NOUN's e-learning environment. This will result in the provision of important assistance to both students and administrators.

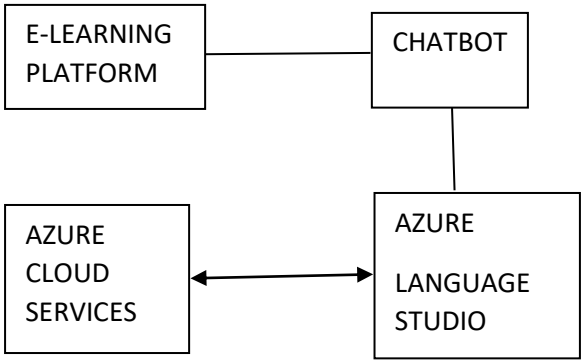

Figure 5: E-learning chatbot architecture

3.4 RESEARCH DESIGN

The research used a survey design methodology. The chosen technique was deemed suitable as it facilitated the researcher in effectively describing, examining, documenting, analysing, and interpreting the variables identified in the study. Moreover, the utility of this data stems from its collection from a quite extensive population. According to Ezejulue and Ogwo (1990), the primary objective of survey research is not only to gather data, but rather to uncover significance within the data gathering process. This approach aims to enhance comprehension, interpretation, and explanation of facts and occurrences. It was emphasised that the phrases "descriptive" and "survey" are used interchangeably to refer to the aforementioned style of study.

3.5 CONSIDERATION FOR MIXED METHODS

The use of a mixed methods approach may considerably increase the e-Learning experience of students at the National Open University of Nigeria (NOUN) while designing a chatbot. Mixed methods research integrates qualitative and quantitative data gathering and analysis methodologies, so facilitating a more full comprehension of the issue at hand and its possible remedies. This research incorporates consideration for mixed techniques in the following manner.

Usage Patterns (Quantitative): Utilize quantitative data analysis to track usage patterns of existing e-Learning resources to identify areas where a chatbot can effectively assist students and enhance engagement.

Chatbot Interface Design (Qualitative): During the design phase, involve students in focus groups or usability testing sessions to get feedback on the chatbot's interface design. Understanding how students interact with the chatbot and what improvements can be made will be valuable in refining the user experience.

Feedback and Iteration (Mixed): Continuously collect both quantitative and qualitative feedback from students while the chatbot is in use. This iterative process allows for continuous improvement and ensures that the chatbot meets the evolving needs of students.

Impact Assessment (Mixed): After the chatbot has been implemented, use mixed methods to assess its impact on the e-Learning experience. Quantitative data can be collected on metrics such as student engagement, course completion rates, and grades, while qualitative data can provide insights into the students' perceptions and experiences with the chatbot.

Contextual Understanding (Qualitative): Employ qualitative methods to understand the specific context of NOUN's e-Learning environment. This can include factors such as internet connectivity, device availability, and unique challenges faced by distance learners.

By incorporating mixed methods research, the design and implementation of the chatbot for NOUN's e-Learning can be more informed and well-rounded, resulting in a more effective and student-centered solution. It allows for a deeper understanding of the students' needs, preferences, and experiences, leading to a more meaningful and impactful chatbot that enhances their learning journey.

3.6 RESEARCH POPULATION AND SAMPLING PROCEDURE

The study population comprises 565,385 students for the school year 2022/2023. According to Unyimadu (2005:36), the term "population" refers to a group of things, persons, or events that possess a shared trait of interest to the researcher. The many terms used to describe this concept include target population, accessible population, limited population, and limitless population.

A total of 379 students, who were identified as NOUN students, were selected for the study using the method proposed by Kercie and Morgan (1970). The research employs convenience and snowball sampling techniques for participant selection. According to Nikolopoulou

(2023), convenience sampling is a non-probability sampling technique that involves selecting units for inclusion in the sample based on their accessibility to the researcher. On the other hand, snowball sampling is a non-probability sampling method in which new units are recruited by existing units to be part of the sample. Snowball sampling is a valuable method for doing research on individuals with special characteristics that may provide challenges in identification, such as those afflicted with a rare illness.

3.7 MEASUREMENT FOR STUDY

The research used a questionnaire as a means of assessing the design of the chatbot. The tools were used to gather data pertaining to the dependent and independent variables included in the investigation. The research used Likert's (1932) modified scale of measuring.

The study instrument had three distinct portions, denoted as A, B, and C. Section A of the study is dedicated to examining the personal data of the participants. In Section B, the constructions of dependent and independent variables were assessed via the use of five questions for each construct, resulting in a total of 20 items. Each variable was assessed using a 4-point internal scale of measurement, consisting of the following categories: Strongly Agreed (SA) with a value of 4 points, Agreed (A) with a value of 3 points, Disagree (D) with a value of 2 points, and Strongly Disagreed (SD) with a value of 1 point for favourably written items. The use of reversed scoring was employed for items that were phrased in a negative manner.

3.8 MEASURES OF DEPENDENT, MEDIATING, AND INDEPENDENT VARIABLE

This section presents a brief explanation of the dependent and independent variables that were used in this study, and the statistical tools that were adopted in the data analyses.

Variables	**Brief Explanation**
Existing e-learning environment at NOUN	This measures online platform designed to facilitate distance learning and provide flexible access to educational resources and course materials for NOUN students across the country and beyond. Simple percentage analysis was used to analyse the data.
Design and develop a chatbot system	This evaluates measure platform for building the chatbot. Options include using a chatbot development framework, a natural language processing (NLP) library, or utilizing a chatbot development platform with pre-built tools and

	integrations. Simple percentage analysis was used to analyse the data.
effectiveness of the chatbot	Measure the frequency and duration of user interactions with the chatbot, assess how well the chatbot handles user queries and successfully provides relevant and accurate answers, Analyse the average response time of the chatbot. Simple percentage analysis was used to analyse the data.
potential benefits and applications of chatbot technology	This measures and evaluates instant and round-the-clock customer support, helping students and facilitator respond to inquiries and resolve issues at any time. Simple percentage analysis was used to analyse the data.

3.9 PRE-TESTING THE INSTRUMENT AND CONTENT VALIDITY

The researcher used the Pearson Product Moment Correlation (PPMC) analysis in order to assess the reliability of the instruments. During the trial testing phase, a sample of 50 students who were not originally included in the main study were randomly chosen from the study region. The selected students were then subjected to the administration of the instruments.

The two study tools were administered for validation purposes inside the Department of Management Information System at Lagos State University. The goal of this study was to ensure that the questions included in the questionnaire were appropriately phrased to align with the respondents' level of comprehension and effectively address the research objectives in a comprehensive manner. The primary objective of instrument validation was to ascertain the face and content validity. Ultimately, the instruments were deemed to be valid for use.

3.10 PILOT STUDY

In the preliminary investigation, a sample size of 50 participants who were not included in the primary study were chosen at random from the designated research region. The acquired data underwent analysis, and the findings of the research were found to be statistically significant.

3.11 DATA COLLECTION STRATEGY

The questionnaires were disseminated via the use of Google Forms and thereafter administered to a selected set of respondents through WhatsApp group and email. The replies obtained from these individuals were then included into the research. The use of the snowball sampling approach precluded researchers from conducting in-person visits to obtain

information from respondents. Due of the pre-existing connections among participants, the snowball approach proved to be efficacious in identifying and finding them.

3.12 DATA ANALYSIS STRATEGY

The rationale for using the Pearson correlation model is grounded in its ability to quantify the presence of a link. In essence, the Pearson product moment correlation analysis quantifies the association between two variables by use of an equation whereby one variable has the potential to exert impact on the other.

The selection of statistical techniques was deemed suitable due to the use of an interval measurement scale and the presence of independent observations.

3.13 SUMMARY

In brief, this chapter provided an overview of the research approach used in the investigation concerning the development of a chatbot aimed at augmenting the e-learning encounter at NOUN. The chapter provides an overview of many aspects related to the issue formulation, suggested solution, tools used, study design, validation procedures, performance assessment parameters, and system architecture. The subsequent chapter will provide an exposition of the findings and analyses derived from the research, which were obtained via the use of a questionnaire. Furthermore, this chapter will delve into the implications that may be drawn from the obtained data.

CHAPTER FOUR
DATA PRESENTATION, ANALYSIS AND FINDINGS

This chapter involves the presentation, analysis, and interpretation of result of the data collected. The data are arranged and analysed in tables following the research questions

ANSWERING OF RESEARCH QUESTIONS

4.1.1 Research Question One:

What are the current challenges faced by students in the e-learning environment at NOUN?

Table 1: analysis of respondent's responses on current challenges faced by students in the e-learning environment at NOUN

S/N	INNOVATIVENESS	SA(%)	A(%)	U(%)	D(%)	SD(%)	Total
1	The e-learning platform provides clear instructions on how to participate in online activities and submit assignments.	105 (27.70)	88 (23.2)	67 (17.6)	60 (15.8)	59 (15.56)	379 (100)
2	The e-learning platform offers interactive features (e.g., discussion forums, live chat) for student collaboration and engagement.	103 (27.17)	88 (23.2)	72 (18.9)	61 (16.0)	55 (14.51)	379 (100)
3	The communication channels (e.g., emails, messaging systems) between students and instructors are effective and responsive.	102 (26.91)	83 (21.8)	70 (18.4)	68 (17.9)	56 (14.77)	379 (100)
4	The e-learning platform	104	83	73	67	52	379

	provides timely and constructive feedback on assignments and assessments.	(27.44)	(21.8)	(19.2)	(17.6)	(13.72)	(100)
5	The availability of support services (e.g., technical support, academic advising) for e-learning students is satisfactory.	103 (27.17)	80 (21.1)	77 (20.3)	62 (16.3)	57 (15.03)	379 (100)
	Aggregate	517 (27.28)	422 (22.2)	359 (18.9)	318 16.78)	279 (14.73)	1895 (100)
	Proportional Ratio	103.4	84.44	71.8	63.6	55.8	**379**

Source: Researcher's Computation (2023).

Analysis of responses of respondents on current challenges faced by students in the e-learning environment at NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 517 representing 27.28% and a proportional ratio of 103.4. This was followed by aggregate of 422 representing 22.27 and a proportional ration of 84.44 who opted for agreed option, Undecided had an aggregate of 359 representing 18.94 and a proportional ratio of 71.8, Disagree option had an aggregate of 318 representing 16.78 and a proportional ratio of 63.6, Strongly Disagree option had an aggregate of 279 representing 14.73 and a proportional ratio of 55.8.

Therefore, based on the above analysis, current challenges faced by students in the e-learning environment at NOUN is statistically significant.

4.1.2 Research Question Two:

How can chatbot technology be applied to improve the e-learning experience at NOUN?

Table 2: analysis of respondent's responses on chatbot technology application and improving the e-learning experience at NOUN

SN	Competitive aggressiveness	SA (%)	A (%)	U (%)	D (%)	SD (%)	Total
1	Chatbots can provide immediate responses to	106 (27.96)	96 (25.32)	78 (20.58)	55 (14.51)	44 (11.60)	379

	students' queries and enhance the accessibility of educational resources.						
2	Chatbots can personalize the learning experience by offering tailored recommendations and content based on individual students' needs and preferences.	103 (27.17)	97 (25.59)	73 (19.26)	0 (16.09)	46 (12.13)	379
3	Chatbots can enhance student engagement and motivation by providing interactive and conversational learning experiences.	109 (28.75)	95 (25.06)	80 (21.10)	50 (13.19)	45 (11.87)	379
4	Chatbots can assist students in tracking their progress and provide feedback on their performance, thereby facilitating self-assessment and self-improvement.	105 (27,70)	90 (23.74)	72 (18.99)	60 (15.83)	52 (13.72)	379
5	Chatbots can support collaborative learning by facilitating group discussions, peer-to-peer interactions, and knowledge sharing among students.	108 (28.49)	96 (25.32)	80 (21.10)	50 (13.19)	45 (11.87)	379
	Aggregate	**531 (27.72)**	**474 (25.39)**	**383 (20.29)**	**276 (14.36)**	**231 (12.24)**	**1895 (100)**
	Proportional Ratio	**105.1**	**94.9**	**76.9**	**55.8**	**46.3**	**379**

Source: Researcher's Computation (2023).

Analysis of response of respondents on chatbot technology application and improving the e-learning experience at NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 531 representing 27.72% and a proportional ratio of 105.1. This was followed by aggregate of 474 representing 25.39 and a proportional ration of 94.9 who opted for agreed option, Undecided had an aggregate of 383 representing 20.29 and a proportional ratio of 76.9, Disagree option had an aggregate of 276 representing 14.36 and a proportional ratio of 55.8, Strongly Disagree option had an aggregate of 231 representing 12.24 and a proportional ratio of 46.3.

Therefore, based on the above data analysis, there is chatbot technology application and improving the e-learning experience at NOUN.

4.2.3 Research Question Three:

What are the design considerations and requirements for developing an effective chatbot for NOUN?

Table 3: analysis of respondent's responses on design considerations and requirements for developing an effective chatbot for NOUN

S/N	DESIGN CONSIDERATIONS AND REQUIREMENTS	SA (%)	A (%)	U (%)	D(%)	SD (%)	Total
1	The chatbot system is user-friendly and easy to navigate.	104 (27.44)	90 (23.74)	81 (21.37)	71 (18.7)	33 (8.70)	379
2	The chatbot provides accurate and relevant information related to my courses and studies.	108 (28.49)	88 (23.21)	74 (19.52)	51 (13.45)	58 (15.30)	379
3	The chatbot understands my queries and responds effectively.	102 (26.91)	93 (24.53)	86 (22.69)	50 (13.19)	48 (12.66)	379
4	The chatbot system has improved my overall e-						

	learning experience at NOUN.	102 (26.91)	91 (24.01)	82 (21.63)	59 (15.56)	45 (11.87)	379
5	The chatbot system has helped me in accessing and locating learning resources more efficiently.	109 (28.75)	90 (23.74)	83 (21.89)	50 (13.19)	47 (12.40)	379
	Aggregate	**525 (27.90)**	**452 (23.85)**	**406 (21.42)**	**281 (14.43)**	**231 (12.40)**	**1895 (100)**
	Proportional Ratio	**105**	**90.4**	**81.20**	**56.2**	**46.3**	**379**

Source: Researcher's Computation (2023).

Analysis of responses respondents on design considerations and requirements for developing an effective chatbot for NOUN reveals that the respondents Strongly Agreed (SA) responses had an aggregate of 525 representing 27.90% and a proportional ratio of 105 This was followed by aggregate of 452 representing 23.85 and a proportional ration of 90.4 who opted for agreed option, Undecided had an aggregate of 406 representing 21.42 and a proportional ratio of 81.20, Disagree option had an aggregate of 281 representing 14.43 and a proportional ratio of 52.6, Strongly Disagree option had an aggregate of 231 representing 12.40 and a proportional ratio of 46.2. Therefore, based on the analysis of study, the design considerations and requirements for developing an effective chatbot for NOUN is effectively tailored to suit leaner's needs.

4.2.4 Research Question Four:

To what extent does the implemented chatbot enhance student engagement and satisfaction?

Table 4: analysis of respondent's responses on implementation of chatbot enhance student engagement and satisfaction.

S/N	implementation of chatbot	SA(%)	A(%)	U(%)	D (%)	SD (%)	Total
1	The chatbot provided helpful and relevant information.	102 (26.91)	94 (24.80)	89 (23.48)	70 (18.46)	24 (6.33)	379
2	The chatbot responded promptly to my queries.	109 (28.75)	89 (23.48)	73 (19.26)	56 14.77)	52 (13.72)	379
3	The chatbot understood my questions accurately.	200 (52.77)	91 (24.01)	23 (6.06)	43 (11.34)	22 (5.80)	379
4	The chatbot enhanced my engagement with the e-learning platform.	102 (26.91)	96 (25.32)	86 (22.69)	73 (19.26)	22 (5.80)	379
5	The chatbot effectively addressed my concerns and provided solutions.	106 (27.96)	93 (24.53)	84 (22.16)	50 (13.19)	46 (12.13)	379
	Aggregate	619 (32.50)	463 (24.43)	355 (18.76)	292 (58.4)	166 (8.80)	1895
	Proportional Ratio	**123.8**	**92.6**	**71.0**	**58.4**	**33.2**	**379**

Source: Researcher's Computation (2023).

Analysis of respondents on implemented chatbot enhance student engagement and satisfaction reveals that the respondents Strongly Agreed (SA) responses had an aggregate of

619 representing 32.50% and a proportional ratio of 123.8 This was followed by aggregate of 463 representing 24.43 and a proportional ration of 92.6 who opted for agreed option, Undecided had an aggregate of 355 representing 18.76 and a proportional ratio of 71.0, Disagree option had an aggregate of 292 representing 58.4 and a proportional ratio of 58.4, Strongly Disagree option had an aggregate of 166 representing 8.80 and a proportional ratio of 33.2. Therefore, implementation of chatbot enhance student engagement and satisfaction.

RESEARCH TESTING

4.2.5 Research question One

Current challenges faced by students in the e-learning environment do not significantly affects learning outcomes at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables

TABLE 4.5

Pearson Product Moment Correlation Analysis of Current challenges faced by students in the e-learning environment and their learning outcomes at NOUN

Variable	$\sum x$	$\sum x^2$	$\sum xy$	r
	$\sum y$	$\sum y^2$		
Learning outcomes at NOUN (x)	9011	270655		
			134663	0.94*
Current challenges faced by students (y)	9113	58989		

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.5 presents the obtained r-value as (0.94). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.94) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between **current** challenges faced by students in the e-learning environment significantly affects learning outcomes at NOUN.

4.2.6 Research Question Two

Chatbot technology application does not significantly improve the e-learning experience at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyze the data in order to determine the relationship between the two variables

TABLE 4.6

Pearson Product Moment Correlation Analysis of chatbot technology application does not significantly improve the e-learning experience at NOUN

Variable	∑x	∑x²	∑y	∑y²	∑xy	r
improve the e-learning experience (x)	9011	270655			140162	0.83*
chatbot technology application (y)		9113	58989			

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.6 presents the obtained r-value as (0.83). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.82) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between chatbot technology application does significantly improve the e-learning experience at NOUN

4.2.7 Research Question Three

The design considerations and requirements for developing an effective chatbot does not improve e-learning at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables.

TABLE 4.7

Pearson Product Moment Correlation Analysis of the design considerations and requirements for developing an effective chatbot for improve e-learning at NOUN

	∑x	∑x²

Variable		$\sum x$	$\sum x^2$	$\sum y$	$\sum y^2$	$\sum xy$	r
Improve e-learning at NOUN (x)		9011	270655				
						141752	0.91*
Design considerations and requirements (y)		9113	58989				

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 12 presents the obtained r-value as (0.91). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.82) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between design considerations and requirements for developing an effective chatbot does improve e-learning at NOUN

4.2.8 Research Question Four

Implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN. In order to test the hypothesis, Pearson Product Moment Correlation analysis was then used to analyse the data in order to determine the relationship between the two variables

TABLE 4.8

Pearson Product Moment Correlation Analysis of Implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN

Variable		$\sum x$	$\sum x^2$	$\sum y$	$\sum y^2$	$\sum xy$	r
student engagement and satisfaction at NOUN (x)		9011	270655				

		134563	0.96*
Implementation of Chabot (y)	9153	58062	

***Significant at 0.025 level; df =375; N =379; critical r–value = 0.086**

Table 4.7 presents the obtained r-value as (0.96). This value was tested for significance by comparing it with the critical r-value (0.086) at 0.025 levels with 375 degree of freedom. The obtained r-value (0.96) was greater than the critical r-value (0.086). Hence, the result was significant. The result therefore means that there is significant relationship between implementation of Chabot does not significantly enhance student engagement and satisfaction at NOUN.

4.3 Discussion of Findings

The significance of the data analysis in table 5 may be attributed to the observation that the calculated r-value (0.94) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311 degrees of freedom. This suggests that there exists a substantial correlation between the prevailing difficulties encountered by students in the e-learning setting and their resultant impact on learning results at NOUN. The observed outcome aligns with the findings of Zulaikha, Mansor, Khairul, and Alias (2021), indicating its relevance. E-learning often necessitates the use of diverse technology, including learning management systems, video conferencing tools, and online collaboration platforms, by students. Various technical challenges, such as those related to software compatibility, hardware constraints, or insufficient technical expertise, might hinder the development of students and give rise to feelings of dissatisfaction. The presence of these problems has the potential to divert students' attention away from their academic pursuits, so exerting an influence on their educational achievements. Therefore, it is possible that e-learning platforms may not provide enough array of materials or full assistance for learning. Challenges in obtaining textbooks, research resources, and academic support services may impede students' educational advancement. The restricted availability of resources and inadequate learning assistance may have a detrimental effect on students' capacity to comprehend intricate topics and ultimately lead to diminished learning achievements. The outcome's importance led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

The significance of the data analysis in table 6 may be attributed to the observation that the calculated r-value (0.83) exceeded the critical r-value (0.086) at a significance level of 0.025,

with 311 degrees of freedom. This suggests that there exists a substantial correlation between the use of chatbot technology and the enhancement of the e-learning experience at NOUN. The relevance of the findings aligns with the research conducted by Frąckiewicz, M. (2023), which posited that chatbots have the capacity to provide customised learning experiences via the provision of personalised information, resources, and advice that cater to the unique requirements of individual students. Through the examination of user data and the use of natural language processing techniques, chatbots have the capability to supply personalised information, address precise inquiries, and offer focused response. Therefore, chatbots has the capability to be developed in a manner that facilitates interactive chats, quizzes, and simulations with students, therefore enhancing the learning experience by increasing engagement and immersion. The use of multimedia features enables chatbots to provide educational information in several forms, including movies, photos, and interactive modules, therefore augmenting students' understanding and retention capabilities. The observed outcome of the study led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis, indicating its substantial importance.

The significance of the data analysis in table 7 may be attributed to the observation that the calculated r-value (0.91) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311 degrees of freedom. This suggests that there exists a substantial correlation between design considerations and needs in the development of a proficient chatbot, as well as the enhancement of e-learning at NOUN. The relevance of the findings aligns with the research conducted by Babington-Ashaye, De Moerloose, Diop, & Geissbuhler (2023b), since the integration of NLP technology facilitates the chatbot's ability to comprehend and address user inquiries in a way that closely resembles human interaction. Natural Language Processing (NLP) facilitates enhanced understanding of diverse phrase forms, user intentions, and contextual information. This facilitates the development of a more captivating and participatory user experience. Therefore, this guarantees the smooth integration of the chatbot and e-learning platform inside the pre-existing systems and infrastructure of NOUN. This integration enables a cohesive user experience and streamlines the retrieval of pertinent student data, educational materials, and scholarly resources. The observed outcome had sufficient importance to warrant the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

The significance of the data analysis in table 7 arises from the observation that the calculated r-value (0.96) exceeded the crucial r-value (0.086) at a significance level of 0.025, with 311

degrees of freedom. This suggests that there exists a substantial correlation between the use of a chatbot at NOUN has been shown to have a considerable positive impact on student engagement and satisfaction. The observed outcome aligns with the findings of Jenneboer, Herrando, and Constantinides (2022). The inclusion of a chatbot has enhanced accessibility for students by offering continuous support. Students have the opportunity to conveniently access information and get help, therefore diminishing their need on in-person assistance during designated office hours. The chatbot system effectively delivered tailored and pertinent information to pupils, effectively answering their individual inquiries. The heightened amount of assistance resulted in a notable rise in student contentment, as they perceived their requirements to be well addressed. The outcome's importance led to the rejection of the null hypothesis and the acceptance of the alternative hypothesis.

CHAPTER FIVE

SUMMARY, CONCLUSION AND RECOMMENDATION

Introduction

This chapter presents a summary of the major findings, conclusion, and recommendations of this study.

5.1 SUMMARY

The purpose of this study was to investigate the construction of a chatbot as a means of enhancing the e-learning experience, with a specific focus on the use of a word as a case study. The architecture of the e-learning environment is tailored to address the unique needs and problems of NOUN. It places emphasis on enhancing student involvement, satisfaction, and support. Chapter three provides an overview of the methods used in the building of the chatbot, along with a comprehensive examination of its architecture, functionality, and integration inside the established e-learning platform at NOUN.

In order to conduct this study, four specific research goals were identified, from which null hypotheses were constructed and then used in the investigation. The literature review was conducted by considering the factors relevant to the study goals. The achievement of this task was facilitated via the utilisation of previous scholarly studies, academic literature, and educational resources. The architecture of the e-learning environment has been carefully tailored to address the unique objectives and problems of NOUN. The primary objective is to enhance student involvement, satisfaction, and support. This chapter provides an overview of the approach used in the construction of the chatbot, as well as a comprehensive examination of its architecture, functionality, and integration inside the established e-learning platform of the National Open University of Nigeria (NOUN). The present document provides a description of the technique used in the creation of the chatbot. This paper examines the iterative design process, including key stages such as requirements collecting, analysis, and user input. The use of user-centric design concepts and the active engagement of stakeholders, including students and teachers, are emphasised in the design process.

This paper examines the incorporation of a chatbot into the preexisting e-learning infrastructure of the National Open University of Nigeria (NOUN). This section elucidates the technological components involved in the integration of the chatbot with the platform's user authentication system, database, and messaging infrastructure. This response focuses on

discussing the design decisions that have been used to create a smooth user experience and promote interoperability.

This section outlines the evaluation and testing strategy for the chatbot system that has been built. It provides an overview of the techniques that will be used to analyse the system's usability, accuracy, and user satisfaction. The discourse is on the engagement of students and teachers in the assessment process and the gathering of feedback to provide iterative improvements. The study had a total of 383 participants. The data obtained from the participants underwent rigorous statistical analysis, and the outcomes of this study were shown to be statistically significant at a significance level of 0.025. The results were thoroughly examined in order to ascertain their alignment or divergence with the conclusions reached by previous studies.

5.2 CONCLUSIONS:

The objective of this study was to introduce a chatbot to enhance students' online learning options at the National Open University of Nigeria (NOUN). The research covered the following crucial issues:

- Current Challenges: Clear instructions, interactive features, communication channels, prompt feedback, and support services are among the difficulties students currently experience in NOUN's e-learning environment. These challenges were statistically significant.

- Chatbot Technology: Most respondents believed that chatbot technology may improve NOUN's e-learning program. They were aware of the quick responses, personalized education, engagement-boosting, progress-tracking, and group learning benefits that chatbots may offer.

- Design Considerations: According to the study, NOUN students were in favor of the requirements and design elements required to build a successful chatbot. They emphasized the value of user-friendly interfaces, accurate information delivery, understanding of user enquiries, enhancing the overall e-learning experience, and efficiently locating learning resources.

- Enhanced Engagement and Satisfaction: It was noticed that the introduction of the chatbot had a considerable beneficial effect on students' engagement. Respondents agreed that the chatbot increased their interaction with the e-learning platform, promptly responded to their questions, correctly understood them, and successfully resolved their issues.

Based on the findings, it is apparent that the integration of a chatbot into the e-learning platform at NOUN may greatly enhance the overall educational experience. The results indicate that the incorporation of a chatbot system has the potential to enhance student

engagement, contentment, and accessibility to support services, while concurrently yielding cost and time efficiencies for the educational institution.

5.3 RECOMMENDATIONS:

The suggestions for the creation of a chatbot to enhance the e-learning experience, as derived from the results of a research conducted at the National Open University of Nigeria (NOUN), are as follows:

There is a need for the administration of NOUN to do a comprehensive examination of the distinct requirements and obstacles encountered by NOUN students throughout their e-learning endeavour. When examining the characteristics of the target audience, it is important to consider their demographic profile, level of technical expertise, and prevalent challenges or difficulties they may encounter. The comprehension of this concept will serve as a framework for the strategic planning, creation, and incorporation of the chatbot.

The design of the chatbot by the management of the NOUN should prioritise a user interface that is both clear and straightforward, effectively emulating natural language exchanges. The primary objective is to ensure that the chatbot comprehends a diverse array of inquiries from students and delivers pertinent information in a conversational style.

The administration of NOUN should maintain the continuous availability of the chatbot to accommodate the varied study schedules of NOUN students. The provision of this availability would facilitate rapid help, timely resolution of inquiries, and enhance overall student satisfaction.

The seamless integration of the chatbot with the NOUN e-learning platform aims to provide a cohesive user experience. The connection facilitates the chatbot's ability to get course materials, participate in discussion forums, submit assignments, and access other pertinent resources, therefore providing extensive assistance inside the platform.

Develop and deploy systems to systematically collect feedback from students on their interactions and overall experience with the chatbot. It is essential to conduct regular analysis of this input in order to discover potential areas for development, enhance the performance of the chatbot, and tweak its replies to effectively cater to the shifting demands of students.

Implement thorough onboarding and training sessions to acquaint pupils with the chatbot's capabilities and operations. This document aims to provide comprehensive guidance and

tools to assist students in maximising their engagement with the chatbot and effectively use its whole range of capabilities.

It is important to consistently assess the performance, use trends, and user feedback of the chatbot in order to evaluate its influence on the e-learning experience. To assess the efficacy of the chatbot and provide evidence-based enhancements, it is essential to monitor many indicators, including student engagement, satisfaction, retention rates, and academic success.

5.4 SUGGESTIONS FOR FURTHER STUDY

The exploration of developing a chatbot with the aim of enhancing the e-learning encounter at the National Open University of Nigeria (NOUN) presents a promising avenue for scholarly investigation. The following recommendations propose potential research investigations that might be undertaken to enhance the design and development of a proficient chatbot system:

Undertake an extensive investigation to ascertain the distinct requirements, obstacles, and inclinations of NOUN pupils in their online learning encounter. Insights into the areas where a chatbot may provide the most value can be obtained by using methods like as surveys, interviews, or focus groups.

Examine the distinct features and capacities that would provide the most advantages for students enrolled at NOUN. This inquiry delves into the many categories of questions or activities that students often request help with, including but not limited to course selection, assignment submissions, accessing resources, and administrative processes. This research has the potential to ascertain the extent and characteristics of the chatbot system.

Examine the design components that lead to a favourable user experience with the chatbot. This encompasses the examination of the chatbot interface's usability, simplicity, and intuitiveness, with the assessment of its visual design and conversation flow. Gather input from students through user testing sessions or surveys in order to progressively enhance the design of the user interface.

This study aims to investigate the possible benefits and implications of integrating personalised suggestions and adaptive learning elements into the chatbot system. This study aims to examine the extent to which the chatbot may modify its replies and recommendations in accordance with the unique preferences, learning styles, and progress of individual

students. This has the potential to augment student engagement and provide a customised learning experience.

This research aims to conduct a comparative analysis to evaluate the efficacy of the chatbot system in enhancing the e-learning encounter at the National Open University of Nigeria (NOUN). This study aims to examine and contrast the levels of engagement, rates of satisfaction, and academic success between students who have access to a chatbot and those who do not. This has the potential to provide empirical data on the influence of the chatbot on student outcomes.

CHAPTER ONE
INTRODUCTION

1.1 Background to the study

The critical flood of Web of Things (IoT) gadgets has altered different areas, including medical services, transportation, savvy urban communities, and modern mechanization. IoT-based frameworks empower consistent availability, information sharing, and mechanization, prompting further developed productivity and upgraded client encounters (Fatima et al., 2022). Notwithstanding, the far and wide reception of IoT additionally delivers critical difficulties, especially relating to security concerns. As IoT gadgets gather and communicate tremendous measures of delicate information, guaranteeing security turns into a basic thought to safeguard people's very own data and keep up with trust in these frameworks.

The Web of Things (IoT) alludes to the organization of actual gadgets implanted with sensors, programming, and network abilities that empower them to gather and trade information over the web. These gadgets can go from ordinary items, for example, brilliant indoor regulators and wearable gadgets to complex frameworks like independent vehicles and modern control frameworks. The IoT biological system empowers consistent correspondence between gadgets, permitting them to assemble data, settle on independent choices, and interface with clients and different gadgets. As of late the quantity of Web of Things (IoT) gadgets has expanded, both in the business and shopper areas. Starting around 2022 an expected 12 billion IoT associated gadgets exist and that number is supposed to increment to 30 billion by 2030, with a third being buyer web and media gadgets (Fatima et al., 2022). With this expansion in gadgets and the utilization of IoT in basic framework applications (for example power plants, independent vehicles, military) secure, protection safeguarding and proficient information the board are vital. The assault surface of IoT gadgets is expanded in contrast with broad IT, because of its more heterogeneous information, correspondence conventions and information the board (Vikas et al., 2022). There is a popularity for secure

IoT applications and sped up development in the IoT business.

Because of the consistent headway and enhancements in AI and IoT, the relevance in their union is promising, yet the difficulties of current AI strategies for IoT information security and productivity are apparent (Lionel., 2022). With the computational impediment of the IoT gadgets, security strategies must be painstakingly chosen, and conventional web security instruments are not dependably

material. AI's promising job in working on the security of IoT frameworks recommends that further examination into this field is proposed.

With the notoriety of IoT gadgets, how much circulated information has expanded radically, advancing the enthusiastic improvement of AI in numerous areas, including, for example, savvy medical care, shrewd home, or programmed recognition of car crashes progressively (Vikas et al., 2022). While the advantage of AI is unquestionable, it requires a lot of information to be gathered and dissected at focal servers, which might be delicate to imparting to different gatherings due to key (business) or protection reasons. Web of things (IoT) applications are engaged with information assortment and examination from society to upgrade our everyday existence (Liehuang et al., 2021). Tremendous measures of information are delivered from the IoT applications, as the majority of these are information driven arrangements. A portion of the inescapable use instances of IoT are savvy home, brilliant city, shrewd matrix, shrewd medical services, modern web of things, and so on. (Vikas et al., 2022). This multitude of utilizations are engaged with taking care of client's confidential information. The cycle incorporates information assortment from the end gadgets, information transmission over the web, information handling at cloud climate, and portrayal of results in the connected UI or as contribution to one more IoT framework for additional outcomes or for change of the conditions where the information are delivered.

IoT information security can be classified as setting focused information protection and content-situated

information security (Liehuang et al., 2021). The client/gadget area and personality are the two primary parts of setting focused information protection. The substance arranged information protection is centered around the real information (Liehuang et al., 2021). Both setting and content-arranged information protection are fundamental. However, in light of the flow use cases, content-arranged information can be gotten to by outsider applications for innovative work. A model use case can be admittance to the patient's delicate information by an outsider examination organization without legitimate assent from the patient. Prior to information (content or setting) is imparted to an outsider, the information proprietor should be appropriately educated and thusly, give assent. There is a disarray about the proprietor of the information. If the individual/association delivering the information is the proprietor or the association taking care of the data is the information proprietor? The association putting away the information possesses the option to store or share the information solely after getting assent from the individual or association delivering it. In some cases information are put away at the gadget (sensors, actuators, client's cell phones), some of the time put away at IoT doors, and at the last stage at distributed storage.

Security is a basic worry in IoT-based frameworks because of the broad information assortment and transmission capacities of associated gadgets. IoT gadgets persistently gather immense measures of individual

information, including area data, biometrics, and personal conduct standards (Emily et al., 2022). Guaranteeing legitimate assent components for information assortment, stockpiling, and use becomes essential to regard people's security freedoms and conform to information insurance guidelines. Safeguarding delicate information from unapproved access, capture, or abuse is an essential security concern. Encryption, secure information transmission, and powerful access controls are basic to keep up with information security and classification in IoT frameworks. IoT gadgets create an abundance of

information that can be utilized for profiling and information examination purposes. While information examination can give bits of knowledge to further developing administrations and encounters, it likewise raises worries about people's protection and the possible abuse of delicate data. A shrewd equilibrium should be kept up with between information use and security assurance. As the IoT information is moved over the web through various organization gadgets and put away at various areas inside the organization, the conventional information security and security rules are insufficient for the insurance of IoT information. Propelled by the abovementioned, different examination have been performed on IoT information security dangers and potential estimations that should be taken for any association to safeguard delicate client information at various layers of the IoT worldview. Our exploration questions and commitments are portrayed beneath. Shrewd gadgets have multiplied throughout the last ten years, and the web of things (IoT) has filled in ubiquity. This is on the grounds that the IoT assumes a significant part in a huge extent of the vast majority's day to day schedules and life (Fatima et al., 2022). A help empowers transmissions among individuals and items.

AI (ML) innovations have been driving the improvement of savvy urban areas and upgrading our regular routines overwhelmingly of information produced from IoT gadgets. (Emily et al., 2022). Transportation, medical services frameworks, home computerization and ecological control are only a couple of the various spaces in which IoT applications can be important. In addition, the Global Information Organization (IDC) conjectures that the quantity of associated gadgets will reach 41.6 billion out of 2025 (Fatima et al., 2022). IoT will contribute due to critical expansion in the volume of information created because of the quick advancement in the quantity of IoT gadgets; it is guessed that how much information produced worldwide will arrive at 180 zettabytes by 2025 (Olumide and Ali., 2020). Regardless of such a promising vision, shopper protection on IoT gadgets is a gigantic concern. Albeit these information show that IoT has colossal future possibilities, a few issues should be settled for this innovation to be more dependable and

usable. These troubles incorporate personality the board, interoperability, normalization, and IoT greening (Fatima et al., 2022). Other significant issues for IoT incorporate protection and security (Liehuang et al., 2021). These gadgets comprise of sensors that can gather information, process it utilizing worked in hardware, and send

them to a far off area. These information are sent to cloud space, where they are accordingly put away and investigated to give the people specific administrations. Conversely, most utilized plans don't give security and namelessness to authentic clients. Flowing disappointments likewise is one of the central points of contention influencing the dependability of edge-helped IoTs, and it falls under the class of safety issues in the IoTs and might possibly prompt security spills (Morshed et al., 2021). Because of their interconnections, these gadgets can trade data through the web as displayed in Figure1. It follows that singular clients' information are gathered. In certain situations, they might contain individual and confidential data about the client, for example, usernames and passwords for online records, email contacts and telephone numbers, contracts and other fundamental archives, installment card and other monetary data, touchy photographs, and different information.

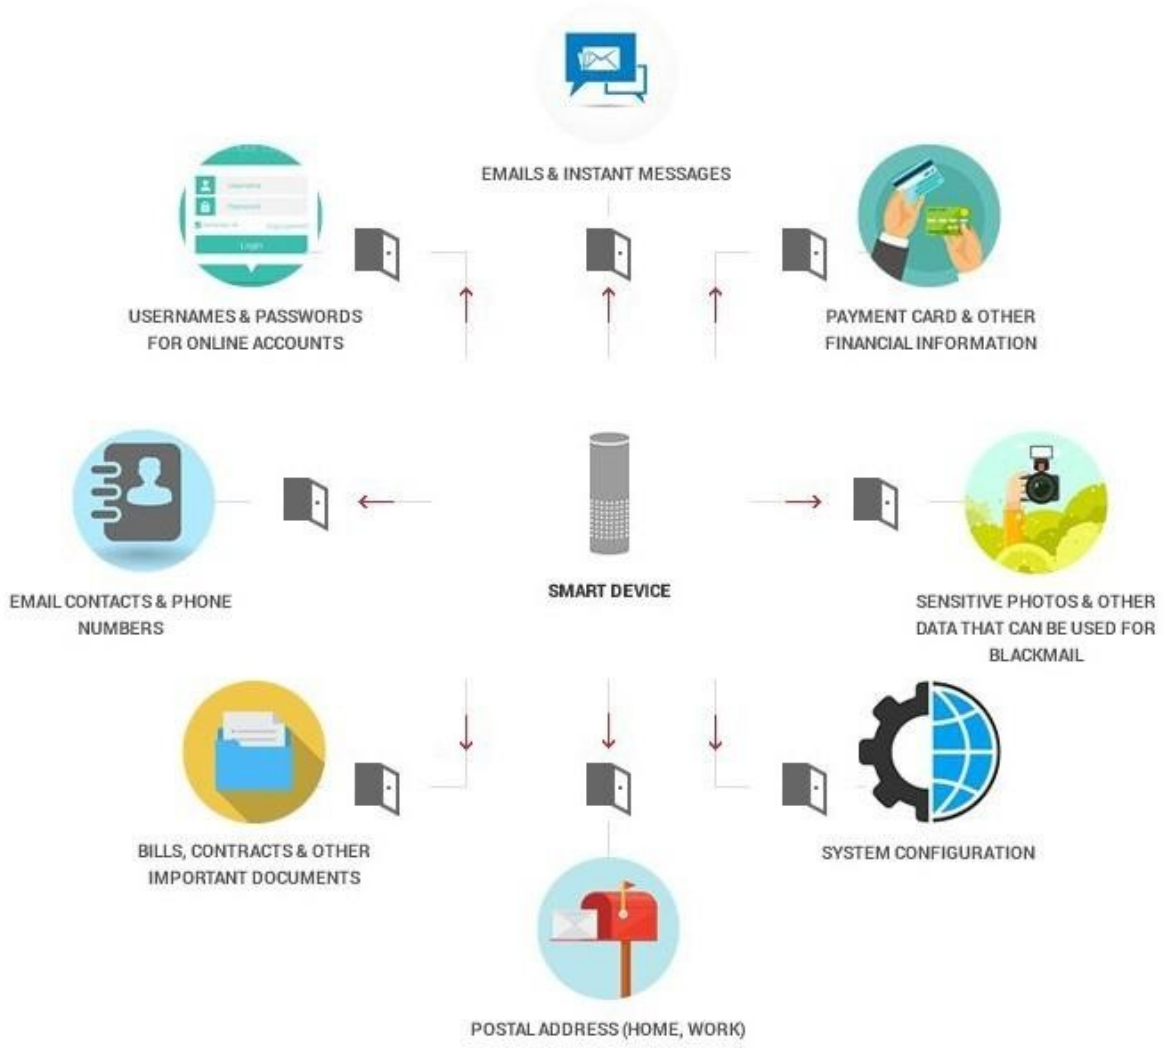

Figure 1.1. Types of information that cyber criminals can gain through different IoT privacy and security attacks.

1.2 Statement of the problem

A few AI models have been sent in past examinations to address security issues inside IoT structures, yet many have shown impressive limits. For example, the work by Ahmed et al. (2020) utilized a k-closest neighbor (KNN) calculation to order network interruptions, accomplishing an exactness of simply 85%, which raised worries about its viability continuously applications where higher precision is basic (Ahmed, A., Mahmood, A. N., and Hu, J. 2020).

Moreover, the review led by Khan et al. (2023) carried out Convolutional Brain Organizations (CNNs) for network security characterization undertakings, accomplishing a 70% exactness rate. Notwithstanding, this model showed an unevenness in review between classes, really intending that while it successfully recognized specific assault types, it neglected to catch a huge piece of the genuine assault occurrences, which could prompt serious security slips in functional conditions (Khan, M. A., and Shah, A. 2023). Similarly, Ghafoor et al. (2021) zeroed in on utilizing Backing Vector Machines (SVMs) for irregularity recognition in IoT conditions. In spite of the fact that their outcomes mirrored a moderate precision of 78%, the model battled with imbalanced datasets, bringing about countless bogus negatives and a failure to satisfactorily distinguish basic assault cases (Ghafoor, K., Chao, H. K., and Majeed, R. 2021).

In spite of these progressions, a typical hole across these examinations is the failure to keep up with high accuracy and review all the while, prompting an unacceptable equilibrium as shown by conflicting execution measurements. Moreover, many existing models experience the ill effects of overfitting because of restricted preparing information, which further effects their generalizability in different genuine situations.

Conversely, this exploration embraces a half breed model using the Irregular Woods (RF) classifier coordinated with Convolutional Brain Organizations (CNNs), pointed expressly at tending to the recognized holes. The crossover RF-CNN model use the qualities of the two calculations — RF's ability for dealing

with organized information and performing highlight determination, close by CNN's power for handling unstructured information and perceiving complex examples. The hybridization of these models can upgrade protection in the accompanying ways: RF is a group learning technique that lessens the gamble of overfitting, accordingly keeping up with precision in any event, when commotion is available in the information (Breiman, 2021). This can assist with relieving the utility misfortune related with differential protection. RF can give bits of knowledge into highlight significance, considering better information the executives and protection saving element determination (Liaw and Wiener, 2022). Convolutional Brain Organizations: CNNs are especially successful for handling and breaking down complex information designs, like those found in IoT conditions. Their ability for include extraction can altogether get to the next level model execution, particularly in situations with huge volumes of information (LeCun et al., 2015). Support Vector Machines: SVMs are especially successful in high-layered spaces, making them reasonable for complex IoT datasets (Cortes and Vapnik, 2020). This capacity can upgrade the model's presentation even with less information because of security imperatives. SVMs can keep up with execution with loud information, which is valuable in conditions where information respectability can't be ensured (Schölkopf et al., 2021).

This incorporation permits the model to accomplish an ideal exactness of 100 percent, with adjusted accuracy and review across classes, consequently guaranteeing dependable distinguishing proof of assaults while limiting misleading up-sides. Thusly, the proposed model upgrades generally speaking grouping execution as well as gives a vigorous structure to adjusting to the developing idea of safety dangers in IoT conditions and means to work out some kind of harmony between protection conservation and information utility, tending to the holes recognized by the recently referenced existing security improving innovations in IoT frameworks.

1.2.1 Research Questions

The examination inquiries for this study are given beneath:

i. What are issues influencing existing related works?

ii. How can an AI demonstrate be created utilizing Irregular Backwoods and Convolutional Brain Organizations (RF and CNN) AI calculations with Help Vector Model (SVM) as classifier?

iii. How could the created framework at any point be executed?

iv. How can the exhibition of the created AI demonstrate against the differential protection, combined learning and Secure conglomeration model, utilizing Exactness, Accuracy and Review as assessment measurements be assessed?

1.3 Aim of the Review

The point of this study is to foster RF-CNN model for upgrading security in IoT-based frameworks. The particular goals are recorded underneath:

1.4 Specific Goals

The particular goals are to:

i. Review existing related attempts to distinguish the holes.

ii. Develop a model utilizing Irregular Backwoods and Convolutional Brain Organizations (RF and CNN).

iii. Implement the created model.

iv. Evaluate the exhibition of the RF-CNN model against the K-closest neighbor and Strategic relapse

model, utilizing Exactness, Accuracy and Review as assessment measurements.

1.5 Scope of the Review

The review will include the accompanying degree:

i. Literature Survey: A careful assessment of existing writing connected with security protecting innovations and techniques in IoT frameworks, including yet not restricted to AI applications, security improving advancements (PETs), and significant systems tending to protection worries in IoT conditions.

ii. Privacy Protection Methods: A top to bottom investigation of cutting edge security safeguarding strategies, for example, Arbitrary Woods and Convolutional Brain Organizations, zeroing in on their parts in improving information protection and honesty inside IoT-based frameworks.

iii. Identification of Security Dangers: A definite order of potential protection dangers, dangers, and weaknesses related with different IoT use cases, giving a primary comprehension of the difficulties that need relief through keen models.

iv. Model Advancement: Plan and execution of a clever model using Irregular Woods and Convolutional Brain Organizations explicitly focused on continuous protection upgrade in IoT conditions. The model will consolidate versatile and setting mindful capacities to suit different IoT applications.

v. Experimental Arrangement: Planning and directing thorough examinations to assess the adequacy of the created model utilizing IoT-produced datasets. This will incorporate situations that reenact genuine circumstances, investigating the associations between protection instruments, model execution, and framework utility.

vi. Privacy Measurements Assessment: Evaluation of the model's presentation as far as security protection utilizing significant measurements, including however not restricted to Genuine Positive Rate

(TPR), Bogus Positive Rate (FPR), accuracy, precision, review, and the Region Under the ROC Bend (AUC).

vii. Performance Examination: A quantitative investigation of the model's viability in protecting security while keeping up with satisfactory degrees of exactness and correspondence proficiency in IoT applications, with correlations with existing models where pertinent.

viii. Discussion and Understanding: An extensive conversation of the discoveries, featuring the ramifications of involving AI procedures for security upgrade in IoT frameworks. This will remember experiences for the compromises among protection and utility, expected applications, and proposals for experts and policymakers in the field.

1.6 Significance of the review

The meaning of this study lies in its capability to address basic security challenges related with the fast extension of Web of Things (IoT) frameworks. The vital commitments of this examination are as per the following:

i. Enhancing Security in IoT Conditions: This study expects to give a hearty answer for upgrading protection in IoT frameworks through the improvement of a shrewd model that successfully mitigates security chances. By using progressed AI procedures, the model tries to safeguard delicate client information while keeping up with usefulness across assorted IoT applications.

ii. Contribution to the Field of IoT Security: As IoT gadgets multiply, the comparing expansion in information age raises critical protection and security challenges. This examination adds to the scholarly talk on IoT security by investigating creative ways to deal with protection safeguarding, filling holes in existing writing encompassing AI applications in this space.

iii. Practical Suggestions for Industry Partners: The discoveries of this study will give important bits of knowledge to industry experts, engineers, and policymakers associated with the plan and arrangement of IoT frameworks. By featuring powerful protection safeguarding techniques, this examination expects to illuminate best practices and guide the improvement of safer IoT conditions.

iv. Framework for Future Exploration: By classifying potential protection gambles and evaluating the viability of various AI procedures, this review lays out a system for future examination in the field of IoT security. It lays the foundation for additional investigation of astute protection models, empowering resulting examinations concerning versatile arrangements customized to arising IoT challenges.

v. Balancing Security and Utility: This study tends to the basic compromises between protection conservation and the utility of IoT frameworks. By exhibiting how exceptional calculations, such as Irregular Timberland and Convolutional Brain Organizations, can upgrade security without considerably compromising model precision or productivity, the examination plans to encourage a stronger and client focused IoT biological system.

vi. Policy Suggestions: The results of this examination can act as an establishment for creating administrative structures and rules pointed toward upgrading security in IoT frameworks. Policymakers will profit from the proposals got from this review, possibly prompting more secure and more capable IoT rehearses around the world.

In synopsis, this study's importance reaches out past scholarly commitments; it looks to propel the comprehension of protection in IoT frameworks and give significant bits of knowledge that can prompt more secure, more reliable, and protection mindful IoT arrangements.

1.3 Definition of terms

i. Internet of Things (IoT) - An organization of interconnected gadgets outfitted with sensors, programming,

and different innovations that empower them to gather, trade, and dissect information over the Web.

ii. Privacy-Upgrading Advances (PETs) - Devices and techniques intended to safeguard people's protection and information classification while empowering the usefulness of frameworks and applications, especially in information sharing settings.

iii. Machine Learning (ML) - A subset of man-made consciousness including calculations and factual models that empower PCs to perform errands without unequivocal programming, principally through gaining from information designs.

iv. Data Investigation - The method involved with inspecting and deciphering informational indexes to separate significant bits of knowledge, examples, and patterns that can illuminate direction and upgrade framework execution.

v. Real-Time Checking - Constant perception of frameworks and information streams, taking into consideration prompt location of inconsistencies and convenient mediations to moderate dangers, including protection breaks.

vi. Random Woods (RF) - An outfit learning technique for order and relapse that develops various choice trees during preparing and yields the method of their expectations, upgrading exactness and heartiness.

vii. Convolutional Brain Organizations (CNNs) - A class of profound learning calculations especially powerful for handling information with network like geography, like pictures or time-series information, using convolutional layers to remove various leveled highlights.

viii. True Positive Rate (TPR) - Otherwise called responsiveness or review, TPR estimates the extent of genuine positive cases accurately distinguished by the model, showing its capacity to identify applicable examples.

ix. False Positive Rate (FPR) - The extent of negative cases erroneously delegated positive by the model, mirroring the pace of deceptions created during protection break identification.

x. Precision - The proportion of genuine positive outcomes to the complete anticipated positive outcomes, demonstrating the precision of the model in recognizing pertinent data of interest.

xi. Receiver Working Trademark (ROC) Bend - A graphical portrayal of a model's symptomatic capacity, delineating the compromise among TPR and FPR at different limit settings; the region under this bend (AUC) is utilized as an outline proportion of a model's presentation.

xii. Privacy-by-Plan - A way to deal with framework plan that coordinates security contemplations into the improvement cycle, guaranteeing that protection insurance is a basic part of innovations and foundations all along.

xiii. Privacy-saving AI: It alludes to a bunch of methods and approaches that mean to safeguard the protection of people's information during the most common way of preparing and surmising of AI models.

xiv. IoT-based action acknowledgment: It includes the utilization of Web of Things (IoT) gadgets to gather

information from sensors and induce human exercises. These exercises can incorporate activities, motions, or ways of behaving performed by people.

xv. Differential protection: a numerical system guarantees the security of people's information by presenting controlled commotion or bother during information examination. It ensures that the presence or nonappearance of any singular's information doesn't fundamentally affect the general outcomes, hence safeguarding protection.

xvi. Federated learning: It is a decentralized AI approach where preparing of models happens on individual gadgets (e.g., IoT gadgets) locally, and model updates are totaled without sharing crude information. It empowers cooperative learning while at the same time protecting information security.

xvii. Secure collection: It alludes to strategies that safely total nearby model updates from various gadgets without uncovering delicate data. It guarantees security during the conglomeration cycle in united learning settings.

xviii. Accuracy: It estimates the accuracy or accuracy of the action acknowledgment models. It demonstrates how well the models can accurately recognize and order different human exercises in view of the info information.

xix. Computational proficiency: It alludes to the capacity of the protection safeguarding AI strategies to play out the expected calculations inside sensible time periods and asset limitations. It incorporates contemplations of handling power, memory utilization, and algorithmic intricacy.

xx. Communication above: It measures the extra correspondence prerequisites presented by protection safeguarding methods. It estimates how much information traded between gadgets or servers during the preparation or collection process, affecting the general productivity and asset utilization.

xxi. Resource necessities: It alludes to the computational assets, like handling power, memory, and capacity, required for carrying out security saving AI procedures in IoT-based action acknowledgment frameworks. It incorporates contemplations for the abilities and restrictions of the gadgets associated with the cycle.

1.4 Organization of the proposal

The examination work is organized into five sections. Part one involves foundation of the review, meaning of the review, articulation of the issue, targets, research questions, extent of the review, limit and association. Part two involves writing survey, section three involves research philosophy, section four arrangements with information investigation and show and section five involves synopsis, end and proposal.

CHAPTER TWO
LITERATURE REVIEW

2.1 Preamble

This writing survey gives a thorough examination and combination of existing exploration zeroed in on improving protection in Web of Things (IoT)- based frameworks through the use of AI strategies, especially the joining of Irregular Woods and Convolutional Brain Organizations. The survey plans to lay out a careful comprehension of the ongoing scene of protection saving innovations (PETs) inside IoT settings, evaluate the viability of different techniques, and distinguish basic holes and impediments in the current collection of information. The quick expansion of IoT gadgets has altogether changed information assortment and investigation across various applications, from shrewd home frameworks to independent vehicles (Kingma and Adams, 2020). These gadgets, furnished with sensors, ceaselessly produce tremendous volumes of individual information, which presents impressive protection challenges. Guaranteeing secure and protection safeguarding information the executives has become fundamental, particularly inside basic foundation applications. This need highlights the investigation of cutting edge AI models, which can give improved arrangement capacities while tending to protection concerns. Existing examination connected with the improvement of protection saving AI for IoT-based action acknowledgment was accomplished through differential protection, with a similar spotlight on united learning and secure collection methods.

Differential protection has arisen as a promising way to deal with address the security challenges in IoT-based movement acknowledgment. By presenting painstakingly aligned commotion or bother during the information examination process, differential security guarantees that the security of people's information is safeguarded, even within the sight of outside assaults or unapproved access (Zhao et. al, 2018). It gives areas of strength for a system to security conservation while keeping up with the utility of the action acknowledgment models. Combined learning and secure accumulation procedures are two unmistakable strategies for protection saving AI with regards to IoT-based action acknowledgment. United learning permits preparing of models on appropriated gadgets while keeping the crude information locally, consequently tending to protection concerns related with concentrated information capacity. Secure conglomeration strategies center around safely accumulating neighborhood model updates without uncovering touchy data, safeguarding protection during the coordinated effort process (Kingma and

Adams, 2020).

Late investigations have featured the capability of wise models that influence Arbitrary Woods for further developed exactness and component choice, close by Convolutional Brain Organizations for compelling protection break identification measurements. Through a definite assessment of these techniques, this survey will feature key discoveries and arising patterns in the exchange between protection upgrade and AI in IoT frameworks, making way for future examination and viable applications that endeavor to cultivate a safe and dependable IoT biological system.

The writing survey envelops a large number of sources, including research articles, gathering papers, specialized reports, and significant books, to guarantee an exhaustive inclusion of the subject. The survey starts with an outline of security challenges in IoT-based movement acknowledgment and the standards of differential protection. It then, at that point, investigates the advancement and utilization of unified learning and secure collection procedures in protection saving AI for IoT-based movement acknowledgment. The audit fundamentally breaks down the qualities and restrictions of differential protection, united learning, and secure collection methods, taking into account their effect on protection safeguarding, precision, computational proficiency, and correspondence above. It additionally looks at the asset necessities and versatility contemplations related with these procedures in IoT conditions. Also, it recognizes possible difficulties and open examination inquiries in the field, preparing for future examinations.

The discoveries and bits of knowledge from this writing audit will advise the ensuing stages regarding the review, including the advancement of examination approaches, information assortment and investigation, and the detailing of proposals and suggestions for upgrading protection saving AI in IoT-based movement acknowledgment. By expanding upon the current information and distinguishing research holes, the review expects to add to the progression of protection safeguarding procedures with regards to IoT-based action acknowledgment and cultivate the improvement of successful and secure frameworks.

2.2 Theoretical Structure

2.2.1 Differential Protection Hypothesis

The review draws upon the standards and ideas of differential protection, a deeply grounded numerical structure. Differential security gives a thorough meaning of protection conservation by evaluating the protection misfortune coming about because of the consideration or rejection of a singular's information in the examination. The hypothesis directs the execution of security saving components, for example,

adding commotion or bother, to guarantee individual protection while keeping up with measurable utility.

Differential protection hypothesis assumes a critical part in improving security safeguarding AI for IoT-based action acknowledgment. It gives a thorough numerical system to guarantee the security of people's information during the investigation and derivation process. By evaluating the security misfortune coming about because of the consideration or avoidance of a singular's information, differential protection empowers the improvement of protection safeguarding instruments that safeguard touchy data while keeping up with measurable utility (Blanchard et al., 2017).

Differential protection can be characterized as a numerical assurance that the presence or nonattendance of a singular's information doesn't fundamentally influence the outcomes or decisions made from a factual examination. At the end of the day, it gives a thorough protection ensure by restricting the impact of any single person's information on the general examination.

One of the fundamental papers presenting differential security is "Differential Protection: A Study of Results" by Cynthia Dwork (2008). The paper gives an extensive outline of the idea, definitions, and key properties of differential security. It lays the basis for understanding the numerical establishments and security ensures presented by differential protection.

Differential protection measures the security misfortune coming about because of the consideration or prohibition of a singular's information in the examination. The idea of responsiveness assumes a significant part in this measurement. Responsiveness estimates how much the result of a capability can change when a solitary information point is added or taken out. Differential security guarantees that the effect of any singular's information on the investigation stays limited to safeguard protection.

An original paper on differential protection responsiveness by Cynthia Dwork et al. (2019) presents the conventional meaning of responsiveness and investigates its relationship with differential security. It gives bits of knowledge into the numerical properties and strategies for estimating responsiveness in various situations.

Differential protection can be accomplished through the execution of security safeguarding instruments that acquaint controlled commotion or annoyance with the information investigation process. These components guarantee that the factual properties and aftereffects of the investigation are saved while safeguarding individual security.

Adam Smith et al. (2011) presents the SuLQ structure, which gives a functional and versatile way to deal with accomplishing differential protection in different information examination undertakings. It presents methods for adding clamor and annoyance to questions while protecting security and keeping up with utility.

Differential security is especially significant with regards to protection saving AI, remembering action acknowledgment for IoT conditions. It takes into account the improvement of AI models that keep up with security ensures while giving precise and helpful expectations.

Abadi et al. (2020) presents a methodology that consolidates profound learning strategies with differential protection to guarantee security in AI models. It investigates strategies for preparing profound brain networks with differential security ensures and gives experiences into the compromises among protection and utility in the educational experience.

2.2 Review of pertinent writing

2.2.1 Machine Learning

ML is a problematic innovation for planning and building smart frameworks that can naturally gain and improve for a fact to achieve an errand without being unequivocally customized (Dwork, 2018). For this reason, a ML-based framework develops a numerical model (i.e., model preparation process) in light of an example set (i.e., preparing information) whose boundaries are to be upgraded during this preparing system. Thus, the framework can perform better expectations or choices on a new, concealed task. Normally, a ML errand can be figured out as a numerical streamlining issue whose objective is to track down the extremum of a goal capability. Hence, an improvement strategy is of foremost significance in any ML-based frameworks.

i. Gradient Plunge Calculation: One of the most generally involved enhancement strategies for ML, which is likewise the center of FL, is angle plummet. It is a first-request iterative improvement calculation for tracking down a neighborhood least of a goal capability, f(θ), defined by a bunch of boundaries. The boundaries update process is iteratively completed until either an adequate nearby least is found or the distinction of the misfortune between two back to back advances is irrelevant (Dwork, 2018).

ii. Gradient Drop Variations: For the most part, there are three angle plummet strategies that are sorted in view of how much preparation information utilized in the slope estimation of the goal capability, f(θ) (Smith et al., 2021). The main classification is clump angle plummet, in which the slopes are figured over the whole preparation dataset, D, for one update. The subsequent classification is stochastic slope plunge (SGD) that, as opposed to cluster inclination plummet, haphazardly chooses an example (or a subset) from D and plays out the boundaries update in view of the slope of this example only (one example for every step, the entire cycle moves throughout the whole dataset). The third one is minibatch angle plunge in which the dataset is partitioned into scaled down groups of n preparing tests (n is the cluster size); the boundaries update is then performed on each less group (single smaller than

expected clump per step).

There is a compromise between the precision of boundaries update and the effectiveness of the calculation in each step of slope drop. By and large, small scale bunch angle drop mitigates the issue of failure in cluster slope plunge and slope swaying in SGD. In any case, it presents the extra hyper-boundary cluster size n, which requires ability and broad experimentation and at times should be physically changed (Abadi et al., 2020). The angle drop typically shows up with enhancers, which are procedures for controlling the learning rate, η, strategically and precisely. Such enhancers integrate with the model boundaries, θ, and the misfortune capability, L, to change the learning rate, η, because of result of the misfortune capability. The most well-known angle based analyzers incorporate Force, Adam, RMSprop, and Adagrad (Bonawitz et al., 2019).

iii. Gradient Drop in Dispersed Learning: In spite of the fact that slope plummet based advancement techniques were effectively taken part in different ML calculations, they have as of late re-acquired a lot of consideration since the development of huge scope conveyed getting the hang of, including FL. In these situations, a mind boggling model, e.g., a profound brain organization (DNN) with a great many boundaries, is prepared on an exceptionally enormous dataset across various hubs. These hubs are called register hubs and assembled into bunches. For productivity, the estimations in the preparation cycle ought to be parallelized utilizing simultaneousness techniques like model parallelism and information parallelism (Bonawitz et al., 2019).

Model parallelism circulates a ML model into various registering blocks; accessible processing hubs are then be alloted to just figure a few explicit blocks. Model parallelism requires little clump information is imitated at registering hubs in a bunch, as well as ordinary correspondence and synchronization among such hubs (Bonawitz et al., 2019).

Information parallelism, all things being equal, keeps the fulfillment of the model on each figuring hub yet segments the preparation dataset into more modest equivalent size shards (otherwise called sharding), which are then dispersed to processing hubs in each bunch (Li et al., 2017). The processing hubs then train the model on their subset as a little cluster, which is particularly powerful for SGD variations in light of the fact that most tasks over minibatches are free in these calculations. Information parallelism can be found in various present day ML structures including TensorFlow3 and Pytorch4.

The two parallelism methods can likewise be joined (supposed Crossover parallelism) to increase the benefits while moderating the disadvantages of every one; thus, a half breed framework can accomplish improved effectiveness

and versatility (Froelicher et al., 2020).

The engineering of a disseminated learning-based framework can be concentrated (i.e., ace slave) or decentralized (i.e., ring). In a concentrated design, slave masters (i.e., laborers) just process slopes; an expert (i.e., a boundary server) gets the boundaries from all specialists and disperses the most recent worldwide boundaries back to the laborers to be refreshed in the following preparation round. This unified disseminated learning requires high-correspondence cost among laborers and a server (Froelicher et al., 2020). In a ring design, there is no concentrated server to facilitate the boundary update; all things considered, every hub both locally processes slopes and performs boundary collection by speaking with different hubs utilizing a Tattle calculation. The ring design requires a productive nonconcurrent refreshes procedure among register hubs; if not, model consistency can't be accomplished (Froelicher et al., 2020). By and by, both incorporated and decentralized structures are expected to gain model consistency, especially when information parallelism is utilized. There are various systems to refresh boundaries to keep up with the consistency of a worldwide model, regarded to a synchronization model among register hubs. In such manner, Nonconcurrent Equal (ASP) (Chen et al., 2019), Mass Simultaneous Equal (BSP), and Old Coordinated Equal (SSP) are the most well-known ways to deal with update boundaries in a circulated learning framework. The BSP and the ASP update boundaries once getting all slopes from a main part of register hubs (boundary synchronization) and from simply any hub (no synchronization), individually. By and large, the BSP is moderately delayed because of the slow down season of stalling though ASP is quicker as it plays out no synchronization; as a compromise, the combination in BSP is ensured yet questionable in the ASP (Goldwasser et al., 2019). The SSP is as a middle arrangement adjusting between the BSP and the ASP that performs loosened up synchronization. In the SSP, figure hubs proceed to the following preparation emphasis provided that it isn't quicker than the slowest hub by β steps, (i.e., the advancement hole between the quickest hub and the slowest hub isn't excessively enormous), which ensures the assembly albeit the quantity of emphasess may be huge. Notwithstanding, as a compromise, the SSP present the β hyper-boundary which is non-insignificant to be calibrated (Goldwasser et al., 2019).

2.1.1 Privacy Preserving Techniques in ML

By and large, security protection procedures for a disseminated learning framework target two principal goals:

i. Privacy of the preparation dataset and

ii. Privacy of the neighborhood model boundaries (from a streamlining calculation like

a slope plunge variation) which are traded with different hubs or potentially an incorporated server (Paillier, 2019).

In this regard, unmistakable protection saving strategies in ML incorporate information anonymization, differential security, secure multi-party calculation (SMC), and homomorphic encryption (Damgrd and Jurik, 2021).

1. Data Anonymization: Information anonymization or DE recognizable proof is a procedure to stow away (e.g., hashing) or eliminate delicate qualities, like by and by recognizable data (PII), so an information subject can't be distinguished inside the changed dataset (i.e., the unknown dataset). As a result, information anonymization needs to adjust well between protection assurance and utility since stowing away or eliminating data might lessen the utility of the dataset. Moreover, when joined with helper data from other unknown datasets, an information subject may be re-distinguished, exposed to a security assault called linkage assault (Kawachi et al., 2017).

To keep from linkage assault, various strategies have been proposed, for example, k-obscurity, l-variety, a k-secrecy based strategy, and t-closeness - a method based on both k-namelessness and l-variety that saves the circulation of delicate properties in a dataset so it decreases the gamble of re-distinguishing an information subject in an equivalent semi identifier bunch (Upper class, 2019).

Tragically, such protection safeguarding procedures can't shield against linkage goes after whose enemies have some information about the touchy traits. This lack in the k-obscurity based techniques calls for various methodologies that offer thorough protection assurance like differential security.

2. Differential Security: Proposed by Dwork et al. in 2006, differential security is a high level arrangement of the bother protection/saving procedure in which irregular commotion is added to genuine results utilizing thorough numerical measures (Nobility, 2019). Thus, it is genuinely unclear between a unique total dataset and a differentially added substance commotion one. In this manner, a solitary individual can't be recognized as any (measurable) question results to the first dataset is essentially the equivalent no matter what the presence of the individual (Upper class, 2019). In any case, there is a compromise between protection assurance and utility as adding an excess of clamor and ill-advised haphazardness will fundamentally devalue unwavering quality and ease of use of the dataset (Rothblum, 2021). Differential protection strategy has been generally utilized in different ML calculations, for example, straight

also, strategic relapse, Backing Vector Machine (SVM) and profound learning, as well as in ML-based applications, for example, information mining and sign handling with ceaseless information (Nobility, 2019).

3. Secure Multi-party Calculation: SMC, otherwise called multi-party calculation (MPC) or protection safeguarding calculation, was first and foremost presented by Yao in 1986 and further created by various analysts. Its impetus is that a capability can be by and large processed over a dataset claimed by various gatherings utilizing their own bits of feedbacks (i.e., a subset of the dataset) so that any party doesn't advance anything about others' information with the exception of the results (Lopez and Trumer, 2021). In particular, n parties P1, P2, ..., Pn own n bits of private information X1, X2, ..., Xn, separately to on the whole figure a public capability f(X1, X2, ..., Xn) = (Y1, Y2, ..., Yn). The main data each party can acquire from the calculation is the outcome (Y1, Y2, ..., Yn) and its own bits of feedbacks Xi. Traditional mystery sharing like Shamir's mystery sharing and obvious mystery sharing (VSS) plans are the basis for the vast majority of the SMC conventions.

SMC is helpful to information security protection in disseminated learning wherein figure hubs cooperatively perform model preparation on their neighborhood dataset without uncovering such dataset to other people. Without a doubt, SMC has been utilized in various ML calculations like secure two-party calculation (S2C) in direct relapse, Iterative Dichotomiser-3 (ID3) choice tree learning calculation, and k-implies grouping calculation for disseminated information mining (Kawachi et al., 2017). Be that as it may, a large portion of SMC conventions force non-unimportant overheads which require further effectiveness upgrades with down to earth sending.

4. Homomorphic Encryption: One more way to deal with protect information protection and security in ML is to use homomorphic encryption procedures, especially in concentrated frameworks, e.g., cloud servers, wherein information is gathered and prepared at a server without revealing the first data. Homomorphic encryption empowers the capacity to perform calculation on an encoded type of information without the requirement for the mystery key to decode the code text (Hostein et al., 2020). Aftereffects of the calculation are in scrambled structure and must be unscrambled by the requester of the calculation. Furthermore, homomorphic encryption guarantees that the decoded yield is equivalent to the one figured on the first decoded dataset.

Contingent upon encryption plans and classes of computational tasks that can be performed

on an encoded structure, homomorphic encryption methods are separated into various classifications like halfway, to some degree homomorphic encryption (SWHE), and completely homomorphic

encryption (FHE) (Doroz et al., 2020). Some exemplary encryption procedures, including Rivest-Shamir-Adleman (RSA), is SWHE wherein basic expansion and duplication tasks can be executed (Doroz et al., 2020). FHE, first and foremost proposed by Graig et al. in, empowers any erratic tasks (accordingly, empowers any positive usefulness) over figure text, yielding outcomes in encoded structures. In FHE, calculation on the first information or the code text can be numerically moved utilizing an unscrambling capability with no contentions.

Despite the fact that homomorphic encryption offers thorough security assurance to people as the first information in plaintext has never been revealed, there is a commonsense impediment in performing calculation over figure text because of the enormous computational above. As a result, utilizing homomorphic encryption in enormous scope information preparing stays unreasonable (Doroz et al., 2020). Strategies that can use the enormous measure of information and increment task execution, are the AI (ML) and Profound Learning (DL) calculations. These calculations can be classified into managed, unaided and support learning.

While considering ML in IoT security, Hussain et al., (2019) portray the general use cases for the various sorts of ML calculations. The principal utilization of managed and unaided learning is for information investigation, while support learning is chiefly utilized for examination and independent direction. A portion of the calculations that ought to be featured are, irregular woodland (RL), brain organizations, auto encoders, generative ill-disposed networks (GAN), and profound Q-organizations (DQN) (Doroz et al., 2020).

Irregular woods is contained various choice trees, each prepared on various haphazardly picked subsets of information and highlights. At long last the forecasts of every choice tree are found the middle value of. The auto encoder is a profound learning model that has two sections, the encoder and the decoder. The encoder abstracts the contribution to a lower highlight space code and the decoder attempts to reproduce the contribution from the code. Generative antagonistic organizations create information tests from the learnt appropriation, and train the two models of the generative and discriminative sort.

At last profound q-networks are a type of profound support discovering that is prepared by

learning the q-capability esteem, which depends on the state and the activity chose.

2.1.2Federated Learning Work process Cycle

Motivated by the exploration and this present reality application (i.e., G-board) by the Google group, the vast majority of the current FL-related research works have zeroed in on the concentrated FL structure (i.e., unified

FL) wherein an organization server plays as a regulator mentioning and collecting preparing results to/from neighborhood hubs. Nonetheless, it doesn't be guaranteed to require a unified server for recreating a worldwide model; all things being equal, nearby hubs can straightforwardly trade their preparation brings about a shared way (i.e., decentralized FL) (Brakerski, 2021). This decentralized preparation approach requires a neighborhood refreshing plan in which a synchronization plot among nearby hubs should be executed - which isn't generally possible in united settings. Research on decentralized FL is still in its beginning phase which is either limited to basic learning models (e.g., direct models) or with the suspicion of full or part synchronization among members (Goldwasser et al., 2019). In this paper, Scientist look at the concentrated FL in which there exists a unified server (i.e., specialist co-op) solicitations to facilitate the entire preparation process. In particular, this coordination server

i. Determines a worldwide model to be prepared,
ii. Selects members (i.e., nearby hubs) for each preparation round,
iii. Aggregates neighborhood preparing results sent by the members,
iv. Updates the worldwide model in view of the collected outcomes,
v. Disseminates the refreshed model to the members, and
vi. Terminates the preparation when the worldwide model fulfills a few necessities (e.g., sufficiently precise).

Neighborhood hubs inactively train the model over their nearby information as mentioned, and send the preparation results back to the server whenever the situation allows. The work process cycle in a concentrated FL system comprising of four stages is as per the following:

Stage 1

Member Determination and Worldwide Model Dispersal: The server chooses a bunch of members that fulfill necessities to be engaged with the preparation cycle. It then communicates a

worldwide ML model (or the worldwide model updates) to the members for the following preparation round.

Stage 2

Neighborhood Calculation: Once getting the worldwide ML model from the server, the members refreshes its ongoing nearby ML model and afterward prepares the refreshed model utilizing the nearby dataset dwelled in the gadget. This step is worked at nearby hubs, and it requires end-clients' gadgets to introduce a FL client program to perform preparing calculations, for example, Unified SGD and Combined Averaging, as well as to get the worldwide model updates and send the neighborhood ML model boundaries from/to the server (Goldwasser et al., 2019).

Stage 3

Nearby Models Conglomeration: The server totals an adequate number of the privately prepared ML models from members to refresh the worldwide ML model (the subsequent stage). This collection system is expected to coordinate some protection saving strategies like secure conglomeration, differential protection, and high level encryption techniques to keep the server from assessing individual ML model boundaries. Stage 4

Worldwide Model Update: The server plays out a report on the ongoing worldwide ML model in light of the amassed model boundaries acquired in sync 3. This refreshed worldwide model will be scattered to members in the following preparation round.

2.1.3Privacy-Safeguarding In Concentrated Learning System

As a ML model can be agreeably prepared while holding preparing information and calculation on gadget, FL normally offers protection ensure benefits contrasted with the conventional ML draws near. Sadly, albeit individual information isn't straightforwardly shipped off a coordination server in its unique structure, the nearby ML model boundaries actually contain touchy data since certain highlights of the preparation information tests are intrinsically encoded into such models (Lopez and Trumer, 2021). For instance, creators in have shown that during the preparation cycle, relationships suggested in the preparation information are covered inside the prepared models, and individual data can be thusly separated. Melis et al., (2017) have likewise called attention to that cutting edge profound learning models disguise inward portrayals of a wide

range of elements, and some of them are not connected with the undertaking being learned. Such accidental highlights can be taken advantage of to induce some data about the preparation information tests. FL frameworks, thus, is helpless against deduction assaults (i.e., participation and remaking assaults). Moreover, nearby hubs latently contribute neighborhood preparing results as well as become refreshed about moderate phases of a worldwide preparation model from a coordination server. This training empowers the chance for pernicious members to control the preparation cycle by giving erratic updates to harm the worldwide model (Cheon et al., 2017), which requires an examination on security models alongside shrewd investigation of protection ensures for an incorporated FL structure.

Appropriately, the FL structure then, at that point, should be fortified by utilizing further security and security instruments to safeguard individual information successfully and to consent to perplexing information insurance regulation like the GDPR. Itemized depictions alongside examination are completed in the accompanying sub-segments.

Assault Models on FL

1. Inference Assaults on FL: As previously mentioned, a prepared ML model contains accidental elements that can be used to separate individual data. In this manner, nearby ML model boundaries from a united streamlining calculation can be taken advantage of by an enemy to construe individual data, especially while joining with related data, for example, model information structure and meta-information. This data can be either unique preparation information tests (i.e., recreation assault) or participation following (i.e., to check in the event that a given information point has a place with a preparation dataset) (Cheon et al., 2017).

Aggressors could do show reversal (MI) assault to extricate delicate data contained in preparing information tests, for example, by recreating agents of classes which describing highlights in grouping ML models (McMahan., 2017). MI assaults don't need the assailant to effectively partake in the preparation cycle (i.e., black-box or uninvolved assaults). For instance, it is feasible to recuperate pictures from a facial acknowledgment model for a specific individual (i.e., all class individuals portray this individual) involving MI by inferring a right weighted likelihood assessment for the objective component vectors (Cramer and Damgard, 2018). In this situation, the trial results show that this MI assault can remake pictures that are outwardly like the casualty's photographs (Rivest et al., 2018).

In FL structure, assailants are not just ready to notice the prepared model boundaries yet in addition partake in the preparation cycle to review the progressions in the refreshed worldwide models in some successive preparation adjusts (i.e., white-box or dynamic assaults), which will heighten the assault. It is shown that MI assaults in view of class portrayal are more difficult than recreating from slopes for order models (Zhao et. al, 2018). In such manner, various recreation assaults were proposed in view of Generative Ill-disposed Organizations (GANs) to orchestrate counterfeit examples which have same measurements (e.g., appropriation) to those in the preparation set without approaching the first information. For example, Hitaj et al. in light of GANs have fostered an assault at client level which permits an insider to deduce data from a casualty by simply dissecting the common model boundaries in some sequential preparation adjusts (Kingma and Adams, 2020). This assault can be achieved at client-side without meddling the entire FL method, in any event, when the nearby model boundaries are muddled utilizing DP procedure. A malevolent coordination server can likewise recuperate incomplete individual information by investigating the proportionality between privately prepared model

boundaries shipped off the server and the first information tests. Recreation assaults utilizing MI and GANs are just practical if and provided that all class individuals in a ML model are undifferentiated from which involves a likeness between the MI/GAN-remade yields and the preparation information (e.g., facial acknowledgment of a particular individual, or MNIST dataset for written by hand digits utilized). Luckily, this precondition is less down to earth in the vast majority of the FL situations.

Be that as it may, it isn't important to completely remake the prepared information; all things considered, gathering credits or participation of the first prepared information from nearby model boundaries can likewise instigate serious protection spillage (e.g., an aggressor can sort out whether a particular information test (of a patient) is utilized to prepare a model of a sickness) (Kingma and Adams, 2020). This is the gauge for the enrollment assault. Creators in (Kawachi et al., 2017) have researched participation assaults in FL and showed the ability of these assaults in both latent and dynamic methodologies. For example, the orientation of a casualty can be derived with an exceptionally high exactness of 90% while leading this assault in a paired orientation classifier on the FaceScrub dataset. Different highlights, which are uncorrelated with the primary errand, can likewise be construed like race and facial appearance (e.g., whether a face photograph is wearing glasses). Nasr et al. proposed a functioning assault approach called inclination rising by taking advantage of the protection weaknesses of SGD

improvement calculations. This assault in view of the connection between's the neighborhood slopes of the misfortune and the heading and how much changes of model boundaries while limiting the misfortune to fit a model to prepare information tests in the SGD calculations. This dynamic participation assault was led on the CIFAR100 dataset showing a high exactness of 74% contrasted with just half in detached assault (Blanchard et al., 2017).

1. Poisoning Assaults on FL: One of the protection saving targets of unified FL is that a coordination server can't examine the information or oversee the preparation cycle at a neighborhood hub. This, in any case, precludes the straightforwardness of the preparation cycle; hence, forces another weakness of another sort of assault called model harming (Dwork et al., 2020). For the most part, model harming assaults target controlling preparation process by taking care of harmed nearby model updates to a coordination server. This kind of assault is not quite the same as information harming, which is less viable in FL settings on the grounds that the first preparation information is never imparted to a server. Hence, this segment is principally devoted to breaking down the model harming assaults in FL. By and large, model harming is

led at the client-side wherein an enemy controls a negligible portion of members for a typical ill-disposed objective, by the same token

i. Corrupting the worldwide model so it joins to a sub-standard which is a bumbling, ineffectual one (i.e., irregular assault), or

ii. Replace it to a designated model (i.e., substitution assault).

Harmed model boundaries shipped off a coordination server can be produced by infusing a secret secondary passage model purposefully. Compromised members break down the designated worldwide model; the harmed model is then prepared on secondary passage information tests utilizing devoted procedures, for example, oblige and-scale as needs be and take care of the boundaries to a coordination server as other genuine members. The goal of this assault is that the worldwide model is supplanted by a joint model comprising of both unique errand and the infused secondary passage sub-task while holding high exactness on the two.

2.1.2 Attacks and Security of Combined Learning

2.1.2.1 Attacks on Unified Learning

As FL has drawn in an ever increasing number of considerations of exploration and applications, different weaknesses of FL models have been investigated to send off assaults, essentially including surmising assault and harming assault (Dwork et al., 2020). To learn nearby clients' information security, Melis et al., (2019) created participation derivation assault by utilizing non-no slopes of the implanting layer of a profound regular language

handling model. A Generative Ill-disposed Organizations (GAN)- based dynamic induction assault was planned by Hitaj et al. (2018) to produce designated private examples of the casualty client. In (Abadi et al., 2020), creators explored the protection spillage in FL and afterward fostered a deduction assault model through utilizing each layer's slope of the objective model. Information harming assault of altered the preparation information through flipping information mark and changing highlights or little areas. In (Bonawitz et al., 2019), model harming assault implanted a worldwide secondary passage trigger in FL models, which is accomplished by embedding stowed away secondary passages into a subset of nearby clients prior to refreshing to the server. By displaying the communications between preparing misfortune and assault execution as an ill-disposed min-max game, the creators planned model harming assault to sidestep the harming identification instrument of FL frameworks.

In any case, the majority of the assault models are explore situated and need hypothetical examination on the assault elements and execution.

2.1.2.2 Protection of United Learning

To safeguard information protection in FL, secure multi-party calculation (SMC) and differential security (DP) are ordinarily utilized arrangements. Despite the fact that SMC offers serious areas of strength for an assurance, the confounded calculation conventions yield possibly un-reasonable overheads for little gadgets, like cell phones. Existing works integrate DP into FL from various viewpoints (Bonawitz et al., 2019). McMahan et al., (2019) presented the primary DP-based FL proposition for safeguarding the security of a repetitive language model. In (Froelicher et al., 2020), a nonconcurrent FL was intended for versatile edge registering in metropolitan informatics utilizing neighborhood differential security to safeguard the protection of self-driving vehicles. Agarwal et al., (2020) concentrated on the ideal correspondence cost with binomial instrument for FL under specific DP conditions. In (Damgrd and Jurik, 2021), DP-based commotion was added two times for information security in FL - the initial time is subsequent to preparing neighborhood client models and prior to refreshing nearby model boundaries, and the subsequent time is during the course of boundary conglomeration. Yet, these ongoing works just spotlight on FL with the situation.

2.1.3 The IoT worldview

A crucial IoT design is a three-layered engineering comprising of an actual asset layer, the organization layer, and the information application layer:

i. Physical layer: This layer comprises of actual assets, for example, sensors and actuators for getting ongoing data utilizing different specialized gadgets.

ii. Network layer: In this layer, different systems administration conventions will be consolidated to lay out a

safe correspondence between the organization gadgets. This layer permits a Gadget to-Gadget correspondence for guaranteeing security and Nature of-Administration (QoS) of the organization (Damgrd and Jurik, 2021).

iii. Application Layer: This layer conveys application explicit administrations, for example, shrewd urban areas, brilliant medical care administrations and so on utilizing ML calculations. This is a significant layer in the IoT network which is defenseless against security assaults. The ML calculation conveyed in this layer guarantees the security and unwavering quality of the IoT organization.

In an IoT reference design, the sensors and actuators are associated with the application through gadget passages and utilize a standard motor for handling. A gadget is an equipment part which is associated with sensors through wired or remote correspondence. On the off chance that the gadgets are not equipped for associating straightforwardly with the frameworks, they use Doors for correspondence. All in all, a Passage is utilized to

convey or interpret the data among gadgets and different parts. The Standard motor in IoT helps in making basic handling rules without requiring any programming. Here, clients can make straightforward principles which educates the framework to perform fundamental activity and answer the approaching occasions.

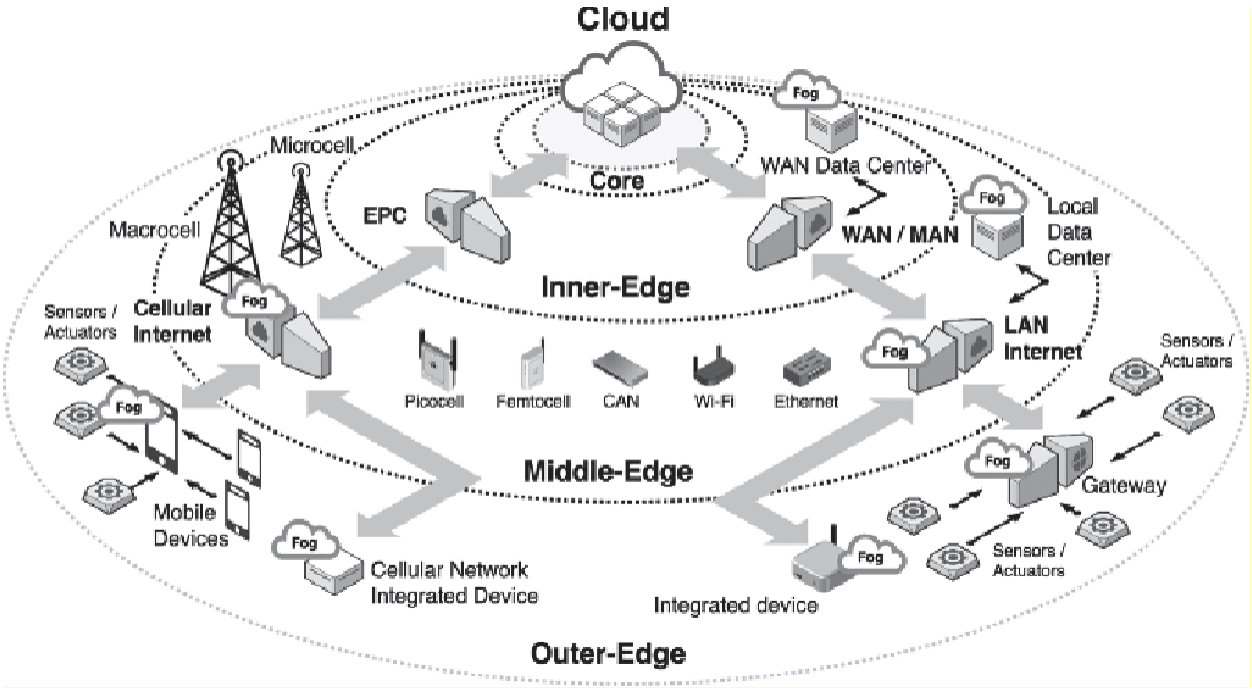

Figure 2.1: IoT Paradigm

2.1.1.1 IoT-based smart environments.

IoT-based brilliant climate alludes to a coordinated framework where the IoT gadgets speak with different gadgets

through an associated organization to work on the QoS. Savvy climate in IoT implies the capacity of IoT gadgets to mechanize their activity, apply information, and go with choices as per the varieties in the outer climate (Paillier, 2019). The starter objective of the savvy conditions is to offer types of assistance in light of the information gathered by the sensors utilizing brilliant procedures. The mechanization of the help will improve on the business cycle and thus the brilliant conditions will assume a urgent part in modernizing the customary method of activity (Upper class, 2019).

Different factors like expanded number of clients, adaptability, and taking care of enormous scope information influences the reception of brilliant conditions. These variables should be considered while taking on IoT based brilliant climate applications.

2.1.1.2 Significance of IoT security

The execution of IoT frameworks accompanies an extensive variety of safety challenges. Tending to the security challenges is a mind boggling and drawn-out task thinking about the powerful idea of the IoT gadgets. A portion of the conspicuous security moves that should be tended to are as per the following:

i. Heterogeneity: The variety of IoT gadgets as far as size, number, data transfer capacity, equipment and programming necessities makes it hard for the scientists to plan a model which can adapt to the heterogeneity.

ii. Volume: IoT gathers information from various sensors and specialized gadgets. Thus there is an enormous volume of information produced in the IoT climate, which is hard to deal with.

iii. Susceptibility to assaults: IoT gadgets are defenseless against different security goes after, for example, treat burglary, cross-site prearranging, organized inquiry language infusion, meeting seizing, and frequently appropriated disavowal of administration.

iv. Latency and dependability: The unmistakable difficulties in the majority of the IoT networks are connected with low-dormancy and unwavering quality issues. Larger part of the innovatively progressed applications, for example, brilliant medical services, path recognition and traffic observing and so on request a low-idleness and high dependability framework design.

v. Cost viability and asset usage: As examined beforehand, IoT is an asset obliged climate, and accomplishing a legitimate tradeoff between the expense adequacy and asset utilization is testing. However the majority of these difficulties are talked about beforehand in different exploration works, the asset limitation nature of IoT alongside its unpredictability and intricacy of tasks have amplified the requirement for tending to these

worries utilizing further developed advancements. In this unique situation, this survey centers around the transformation of FL and DL models for IoT security and talks about the condition of-workmanship, difficulties, benefits and impediments of these models.

2.1.1.3 Security assaults in IoT

Mix of IoT with outside conditions empowers a shrewd and robotized collaboration between the gadgets with its environmental elements. Overall IoT gadgets speak with actual words to perform various assignments. In any case, the security of these gadgets require a top to bottom examination of the

Gadget ascribes and their way of behaving in digital and actual conditions (Rothblum, 2021). As examined beforehand, planning a powerful security structure for distinguishing different digital assaults in IoT is a difficult undertaking. This issue can be more convoluted for getting remote organizations. Since the vast majority of the IoT gadgets work in an open and unified and unattended climate, it turns out to be simple for the gatecrashers to acquire unlawful admittance to these gadgets and take advantage of delicate and private data through listening in. Likewise, IoT gadgets are portrayed by their restricted calculation and high asset utilization which adds to the current difficulties and results in potential dangers turning out to be more plausible (Abadi et al., 2020). A danger is characterized as a demonstration which can take advantage of the weaknesses of the security in a framework and adversely affect it. Dangers are fundamentally classified as dynamic and detached dangers (Chen et al., 2019). Dynamic dangers incorporate Sybil assaults, malware examination, gadget mocking, man-in-the-center assaults, and forswearing of administration (DoS) assaults. Then again, aloof dangers incorporate listening in, phishing assaults and so forth. These assaults significantly affect the viability and dependability of the IoT framework.

The expected dangers and assaults that influence the protection and uprightness of the IoT framework are delineated in the unmistakable security properties that are considered while planning a potential IoT security structure are as per the following:

i. Confidentiality: Secrecy is one of the pivotal boundaries in the IoT frameworks. It is fundamental to guarantee that the significant data put away in IoT gadgets isn't gotten to by any unapproved elements. Be that as it may, in a portion of the cases like monetary applications, albeit the conveyed information is scrambled and is moved privately, gatecrashers can get sufficiently close to the gadget information and control it. This dangers the secrecy of the framework information and confines the flexibility of IoT gadgets (Dwork et al., 2020).

ii. Integrity: The uprightness of the gadget data can be reinforced by permitting the entrance of information just to approved substances. Since a significant part of information is conveyed through remote organizations, the

IoT network turns out to be more defenseless to digital assaults. Trustworthiness guarantees a proficient confirmation process for distinguishing the progressions in the correspondence while imparting over a shaky remote organization. Uprightness safeguards the framework from different noxious dangers which can present SQL infusion assaults (Abadi et al., 2020). Honorable absence can diminish the activity of the IoT gadgets in the event that not distinguished in the beginning phases.

iii. Authentication: The character of the client or gadget ought to be known prior to playing out any errand. In any case, because of the unique way of behaving of the IoT frameworks, the verification cycle contrasts starting with one framework then onto the next. Thus it is fundamental to consider the gadget credits and functionalities while planning a fitting verification system. Likewise, the plan of an confirmation framework should accomplish a legitimate tradeoff between the framework necessities and security imperatives to foster a strong security approach (Abadi et al., 2020).

iv. Authorization: Information approval plans are mostly utilized for safeguarding the delicate data by guaranteeing an approved admittance to the information. Approval plans utilize different access strategies and tokens to characterize a particular control activity and in this manner approves the activities performed on IoT applications. As a rule, approval plans are named strategy based and token based structures (Bonawitz et al., 2019). Strategy based approval plans are more suitable for brought together systemswhich rely upon a focal waiter for access control. Then again, token based plans are more appropriate for decentralized frameworks and are more profitable contrasted with strategy based plans.

v. Availability: In IoT frameworks, the information gathered from various gadgets ought to be accessible either on the private or public cloud. Information accessibility in IoT frameworks envelops both equipment and programming viewpoints. Equipment accessibility guarantees that information can be promptly gotten to by IoT gadgets, while programming accessibility requires that administrations gave to end clients are approved before access is allowed (Damgård and Jurik, 2021). This diverse way to deal with security is fundamental for keeping up with the respectability and dependability of IoT arrangements.

vi. Non-disavowal: Non-renouncement gets the dependability and reliability of the information divided among two frameworks. Non-disavowal guarantees that the legitimacy of information can't be denied since it gives the confirmation of the beginning of information, dependability, and uprightness of the information (Paillier, 2019).

2.1.1.4 Security difficulties in IoT.

The security of Web of Things (IoT) frameworks faces different difficulties across various layers of the organization.

Key assault vectors include:

i Denial of Administration (DoS) and Appropriated Forswearing of Administration (DDoS) Assaults: These assaults basically focus on the organization layer, compromising assistance accessibility. Powerful arrangements incorporate secure IoT offloading, vigorous access control components, and methodologies to guarantee information accessibility notwithstanding heterogeneous gadget conditions.

ii. Jamming Assaults: Likewise focusing on the organization layer, sticking can prompt the personality spillage of gadgets and posture huge dangers to classification. Countermeasures center around upgrading gadget verification and carrying out vigorous security measures.

iii. Phishing Assaults: This type of digital danger, influencing the organization layer, underscores the requirement for solid validation systems to safeguard client characters and delicate data.

iv. Intrusions: Happening at the application layer, interruptions feature the need for severe access control and interruption discovery frameworks to defend basic applications from unapproved access, including malware recognition rehearses that can kill dangers before they really hurt.

v. Eavesdropping: Focusing on the actual layer, listening in takes advantage of weaknesses in information transmission, undermining classification. To alleviate these dangers, guaranteeing secure gadget joining and correspondence protocols is vital.

2.1.1.2 Machine learning for IoT security

AI and profound learning strategies depend on man-made brainpower which assumes a significant part in distinguishing malware and noxious organization traffic in IoT frameworks. In traditional assault discovery frameworks, location of vindictive organization traffic and characterization of organization assault is performed utilizing predefined systems and capabilities. Thus, these methods neglect to distinguish new sorts of assaults and are confined to go after discovery of explicit kinds. This constraint can be settled utilizing ML calculations which gain from past experience as opposed to relying upon certain predefined rules and particulars (Lopez and Trumer, 2021). A few exploration works have carried out and approved the viability of ML calculations for the security of IoT lately (Smith et al., 2021). It tends to be derived from these examinations that ML calculations can deal with the unique way of behaving of IoT frameworks without requiring any manual mediation. Consequently, ML calculations can be utilized for recognizing different IoT assaults in the beginning phase by checking.

AI is worried about the improvement of approaches that PCs learn in light of given inputs (highlights, attributes, however barely introduced in crude information). These methodologies can be measurable or hereditary calculations that quest for examples and connections inside datasets, known as preparing process. After the preparation interaction, the calculations can yield models, boundaries, loads or edges which portray the connections among the info information. AI strategies are supposed to have the option to learn in the event that the strategy effectively track down a describable connection among data sources and results. Any result will ultimately permit the machine to act as needs be and thus, accomplish the objectives of expectation, streamlining, acknowledgment, arrangement or other decision making for the sometime in the future.

As goals can change in various applications, many methodologies have been acquainted with Machine

Learning, regularly visits and probabilistic hypotheses specifically. For example, Fisher's straight discriminant, Head Part Examination (PCA), factor investigation, Authoritative Discriminant Examination (CDA) all utilization factual technique to distinguish detachable highlights which can directly separate between the two information classes. Then again, Viola and Jones (2010) had proposed to involve a fountain of helped classifiers for face identification. The fountain was planned so that it speeds up the recognition cycle. With a few layers in the fountain, countless negative subwindows can be wiped out rapidly which speeds up the face identification process. For instance, the probability of pouring today relies upon the other day, or seasons or experience. Regular probabilistic classifiers that look for connections in the information are Credulous Bayes, calculated relapse or Bayesian choice trees. By and large, all measurable or numerical models can recognize information, as indicated by its class during the educational experience in the event that the designated marks or values were given, which is known as directed learning.

In certain circumstances, datasets can be so enormous and complex that clients have practically no information to move toward their concerns. In such circumstance, strategies applied in AI can be utilized to look for examples or attributes among information. This educational experience is viewed as unaided learning. This looking (or educational experience) necessities to look for and sum up the critical highlights of the datasets with no forthright outcome present in the computation. For instance, k-implies bunching, which utilizes a centroid-based way to deal with parcel information objects in view of the group focal vector tracked down in the information. Other bunching calculations might approach the

datasets in view of network, thickness, or conveyance of the information. For instance, Assumption Boost (EM) characterizes objects having a place in view of Gaussian circulation models. EM approach can be complicated, as they catch corresponded and subordinate relations of information which might prompt indistinguishable because of exceptionally related credits.

Other notable methodologies for general issues or explicit assignments include: Arrangement and Relapse Tree (Truck), Irregular Woods, Inclination Supporting Machines (GBM). These depend on rationale moves toward that give a complete way to deal with straight AI issues. The advantage is that scientists can undoubtedly comprehend the connection between the hubs which addresses an element in an occasion to be ordered. Choice tree likewise ventures into the standard based calculations by having a bunch of rules for every way from the root to a hub in a tree. AI approaches might be likewise gotten from a bunch of strategies joined to manage profoundly connected information. Dalal and Triggs (2020) had utilized a help vector machine (SVM) paired classifier with Hoard elements to recognize people. Support

vector machine will find an ideal hyperplane that parts the preparation tests into gatherings. With the ideal hyperplane, the SVM classifier can bunch the items as indicated by their group.. Helping, Booststrapped Collection (Packing), and AdaBoost apply comparative thoughts called group, to make generally speaking forecast by joining numerous autonomously prepared models as shown on Figure 2.1. A few techniques are well defined for purposes like dimensionality decrease, for example, Fractional Least Square Relapse (PLS) and Sammon Planning endeavors to lessen dimensionality of information connection to diminish the intricacy in the outcome.

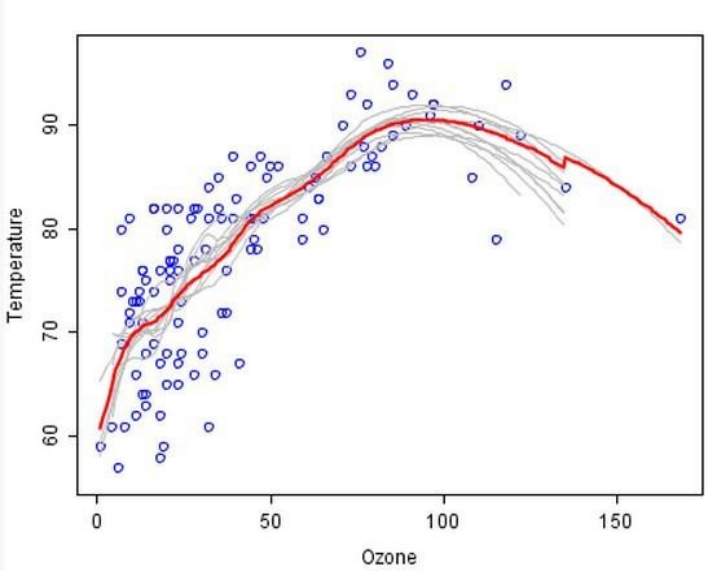

Figure 2.2: The fundamental standards of sacking.

AI strategies have been applied to find information connections at significantly more testing levels like penmanship, division or other exceptionally complex ways of behaving. Despite the fact that Help Vector Machine (SVM) or Gabor channels were well known decisions, which outflanked most learning calculations across various applications, the connection between information or data conveyed in the actual information can be serious to such an extent that, generally utilized measurable or numerical models are not adequate. Profound Learning is one of the proposed strategies that intend to find better portrayals of the data sources. The thought behind Profound Learning contends that machine can learn through an ordered progression of elements, on the off chance that information portrayal can be coordinated into a pile of layers as per its degrees of reflections. This contention has in a roundabout way made the
pattern of planning Profound Learning models, and has uniquely rebranded the utilization for Counterfeit

Brain Organizations (Collobert, 2021). The outcome of Profound Learning brain networks has additionally persuaded this undertaking.

Generally, the objective of utilizing AI methods is to search for the connections inside information, for example designs. Numerous procedures have been recommended to adapt to information intricacy, and have skillfully conveyed the outcomes. Notwithstanding, this present reality information is constantly overwhelmed with data that relies upon many elements. Frequently, these information classes need concentrated work, designing elements to pre-process the information before it tends to be advanced proficiently by the machine, which prompts the development of Profound Learning, especially Profound Brain Organization. Profound Brain Organization (DNN) has now become one of the pioneers among AI strategies to perform different complex errands, for instance, object acknowledgment. The commitment from DNN structures is obvious, and there should be reasons. The resulting segments will introduce a superior understanding of Profound Brain Organization. The following area will start with the idea driving Profound Brain Organization - Profound Learning (Kussul, E., 2018).

2.1.1.3 Privacy in IoT Applications and Correspondence Model

By and large, a typical IoT correspondence model comprises of a few elements like clients, specialist organizations, and outsiders. It is additionally characterized by a few cycles, for example, information detecting, cooperation, assortment, and show. Ziegeldorf et al., (2019) present an IoT model with 4 di erent IoT substances. Those elements are savvy things (IoT sensors, actuators), administrations (backends), subjects (people who get information as well as produce/send information), and foundations (counting network sub-elements based correspondence innovations). They additionally present 5 different IoT information streams: connection, show, assortment, dispersal and handling.

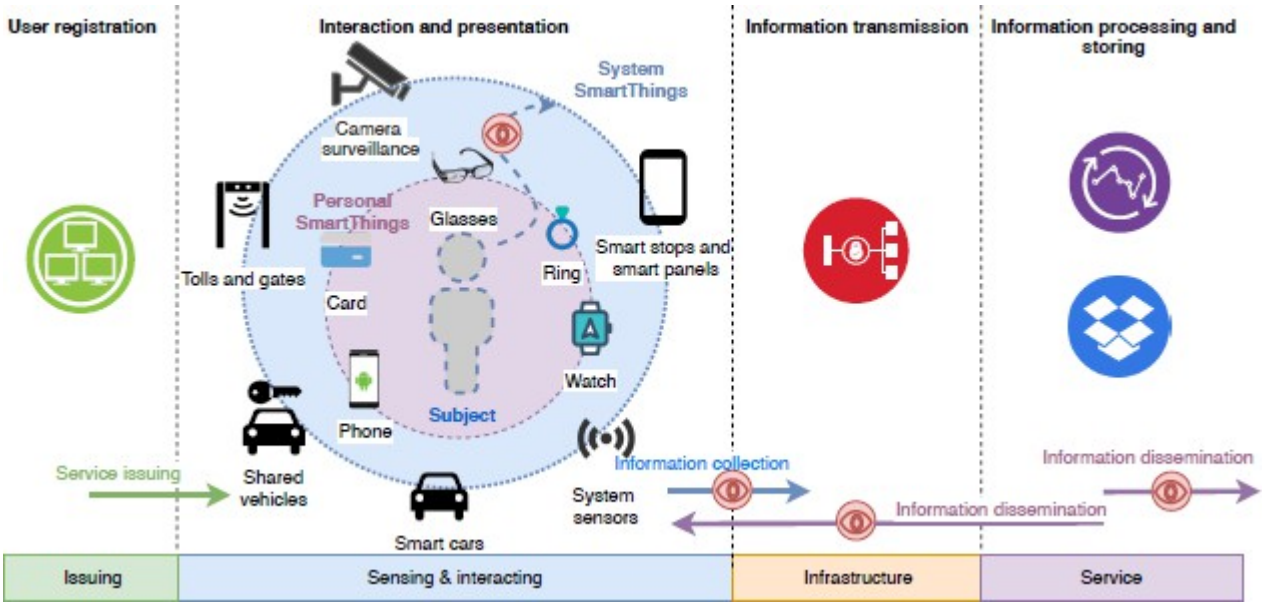

Figure 2.3: View of an IoT model

Figure 3 portrays our perspective on an IoT model and potential security penetrates that are set apart with eye symbols. The human connection with nearness and area IoT shrewd things (sensors, interfaces) may prompt a few security dangers and spillages that must be moderated. In this paper, Analyst focus on protection required IoT applications and security issues in IoT. Scientist additionally give an evaluation of specialized based PETs in different IoT applications. In light of the consequences of our order and evaluation, Specialist propose a clever general system that ought to address potential security spillages and dangers inside information processes in different IoT situations. Our structure upgrades customary protection safeguarding models (for example Hopeman's eight protection plan techniques (Hopeman et al., 2018)) by substantial advances and security saving specialized countermeasures appropriate for private and secure IoT administrations. With the new accommodations guaranteed by IoT comes new protection and security weaknesses. In a space where regularly the gadgets included are obliged and as such don't have the abilities of running powerful security, Specialist see authoritative weaknesses. In this segment, Specialist will investigate some particular use instances of IoT where clients have or may encounter protection issues in no structure.

In late 2015, two security scientists had the option to show that north of 68,000 clinical gadget frameworks were uncovered on the web, and that 12; 000 of them had a place with one medical services association (Smith et al., 2021). The central issue with this revelation was that these gadgets were associated with the Web through PCs running exceptionally old variants of Windows XP, a rendition of

the operating system which is known to have bunches of exploitable weaknesses. This rendition of Windows albeit dated is still right up to the present day piece of a large number

inheritance frameworks around the world, adding to the future protection dangers to IoT gadgets associated with such frameworks. These gadgets were found by utilizing Shodan, a web index that can find IoT gadgets online that are associated with the web. These are not difficult to hack by means of savage power assaults and utilizing hard-coded logins. During their exploration, the two specialists found sedation gear, cardiology gadgets, atomic clinical frameworks, implantation frameworks, pacemakers, attractive reverberation imaging (X-ray) scanners, and different gadgets all by means of basic Shodan inquiries. Albeit not yet at any point revealed, quite possibly programmers accessing clinical gadgets might change settings to these gadgets which could hurt somebody associated with such a gadget.

For shrewd home IoT, one legitimate assault is the Unique finger impression and Timing based Sneaking around (FATS) assault introduced by Srinivasan et al. in (Smith et al., 2021). The FATS assault includes action identification, room grouping, sensor characterization, and action acknowledgment from Wi-Fi traffic metadata from a sensor network conveyed in the home the forerunner to the present shrewd home IoT gadgets. The FATS assault depends on remote organization traffic rather than perceptions from a last-mile Web access supplier or other enemy situated on a Wide Region Organization (WAN). The FATS assault shows that traffic examination assaults in the style of FATS are as powerful for the ongoing age of customer IoT gadgets as they were for sensor networks a decade prior.

In another huge true assault, a new article in Forbes magazine featured research by Noam Rotem and Ran Locar at vpnMentor, who uncovered a Chinese organization called Orvibo, which runs an IoT the executives stage. They showed that their data set was effectively available through direct association with it, uncovering straightforwardly client logs which contained 2 billion records including client passwords, account reset codes, installment data and, surprisingly, some \smart" camera recorded discussions. The following is a rundown of information that was accessible through this pivotal break.

i. Email addresses
ii. Passwords
iii. Account reset codes
iv. Precise Geolocation
v. IP Address
vi. Username (ID)

vii. Family name

This particular break pinpoints the kind of information can be accessible through unstable IoT gadgets or organizations. Consider another IoT use case including helped living, were Specialist consider senior residents who value living autonomously as summed up in (Hopeman et al., 2019). In this situation, various unpretentious sensors screen their important bodily functions and convey data to the cloud for quick access by relatives and outsiders like specialists, and medical services suppliers. There are two degrees of protection issues here, one managing senior resident clinical data and the other with their own information. Consolidating IoT gadgets for observing vitals and capacity instruments like distributed storage can introduce another space of issues attempting to incorporate obliged gadgets (IoT) with the unconstrained (distributed storage). Significant social moves originate from the need to adjust Savvy City administrations to the particular qualities of each and every client. A help sent in a Shrewd City might have numerous setups choices, contingent upon client assumptions and inclinations; the information on these inclinations typically implies the achievement or disappointment of an assistance. To adjust a support of the particular clients inclinations, it is important to know them, and this is essentially done in view of a portrayal of that particular client. By the by, a total portrayal of client inclinations and conduct can be considered as an individual danger, so the incredible cultural test for this, and for any help requiring client portrayal, is to guarantee clients protection and security. Subsequently, to accomplish client assent, trust in, and acknowledgment of Shrewd Urban communities, combination of safety and protection saving components should be a critical worry of future examination. The general need should be to lay out client trust in the impending advancements, as any other way clients will wonder whether or not to acknowledge the administrations given by Brilliant Urban areas.

Soon independent vehicles will be typical. Meanwhile, the improvement of Web of Vehicles (IoV) is progressing where a bunch of sensors, gadgets and regulators are joined to vehicles with an end goal to take into consideration independent control. It is very vital for plan a security mechainism which guarantees that assortment of IoV Large Information is trusted and not messed with. There is a gigantic gamble of deceitful messages infused by a pernicious vehicle that could without much of a stretch jeopardize the entire traffic system(s) or might actually utilize the whole organization to seek after any risky movement for its own devilish advantages.

At long last, Solanas et al., (2020) examine the ideas of Brilliant Wellbeing (s-Wellbeing), as the collaboration

between versatile wellbeing and savvy urban communities. Despite the fact that s-Wellbeing could assist with relieving numerous wellbeing related issues, its capacity to assemble uncommon measures of data could jeopardize the protection of residents. With regards to s-Wellbeing, the data accumulated is in many cases rather private. From the information, it would be

conceivable to construe residents' propensities, their societal position, and, surprisingly, their religion. This large number of factors are extremely touchy, and when they are joined with wellbeing data, the outcome is much more fragile. This s-Wellbeing situations are additionally extremely connected with brilliant wellbeing frameworks where defensive hardware (like caps, glasses or hazardous materials suites) is being checked and followed. The protection concerns utilized match the rundown from (Hopeman et al., 2019), where Finn et al. recognize 7 protection concerns, characterized as follows:

i. Privacy of individual: includes the option to keep body works and body attributes hidden.

ii. Privacy of conduct and activity: this idea incorporates touchy issues like sexual inclinations and propensities, political exercises and strict practices.

iii. Privacy of correspondence: intends to keep away from the capture attempt of interchanges, including mail interference, the utilization of bugs, directional amplifiers, phone or remote correspondence block attempt or recording and admittance to email messages.

iv. Privacy of information and picture: incorporates worries about ensuring that people's information isn't consequently accessible.

v. Privacy of contemplations and sentiments: Individuals have a right not to share their considerations or sentiments.

vi. Privacy of area and space: people reserve the privilege to move about openly or semi-public space without being recognized.

vii. Privacy of affiliation: says that individuals reserve an option to connect with whomever they wish, without being observed.

2.1.1.3 Categorization of Protection Issues: Dangers, Spillages and Assaults in an IoT Climate

In this part, Specialist order security issues and present brief depictions, potential counteraction draws near and compromised IoT regions. Security assaults and protection dangers in IoT have been examined in different examinations. Lopez et al., (2019) identify 3 IoT security issues: client protection, content protection and setting protection. Besides, there have been seven security danger classifications for IoT given in our examination presents 12 protection issues separated into 3 classes:

i. Privacy dangers: this class addresses the shortcomings and defects of IoT administrations and frameworks that could be abused by other framework elements or potentially lead to spillages and assaults,

ii. Privacy spillages: this class addresses more difficult issues and imperfections that can straightforwardly break client protection as well as can be abused by latent and dynamic aggressors,

iii. Privacy assaults: this class addresses gives that are purposefully performed by aloof and dynamic assailants to break client security and abuse the noticed data for crimes.

Analyst arrange general security insurance and avoidance approaches as follows:

i. Data minimization: restricting information assortment to just fundamental data.

ii. Data anonymization: scrambling, changing or eliminating individual data so that the information can as of now not be utilized to distinguish a characteristic individual.

iii. Data security: the method involved with safeguarding information from unapproved access and information defilement.

iv. Data control: checking and controlling the information by denning strategies.

v. Identity the board: strategies and advancements for guaranteeing that the legitimate clients approach innovation assets.

vi. Secure correspondence: correspondence convention that permit individuals imparting data to the fitting secrecy, source validation, and information respectability assurance.

vii. User mindfulness/informed assent straightforwardness: clients give their assents about information utilization and they know which information are handled.

To be noticed, that a few additional mind boggling assaults can be performed by the mix of a few security spillages and dangers.

2.1.1.4 Categorization of Protection Improving Advances for Web of Things

In this segment, Analyst present and classify protection improving advances. Specialist center around PETs that can be;

i. Implemented in gadgets,

ii. Used as applications (client side),

iii. Applied in networks,

iv. Applied in information capacity, cloud and back-end servers.

PETs might give these essential security highlights:

i. (P1) obscurity: client isn't recognizable as the wellspring of information (client is indistinct).

ii. (P2) pseudonymity: user is identifiable only to system parties (issuers), trades of among obscurity and responsibility.

iii. (P3) unlinkability: activities of a similar client can't be connected together, and all meetings are unlinkable together.

iv. (P4) untracebility: client's qualifications and additionally activities can't be followed by framework parties (backers).

v. (P5) renouncement: a committed framework party can eliminate individual or its certification from the framework.

vi. (P6) information security: put away or potentially delivered data don't uncover undesired properties, for example characters, client's fundamental information and so on.

Further, PETs join protection highlights with normal security elements, for example,

i. (S1) information classification: touchy information are safeguarded against snoopping and uncovering by encryption procedures.

ii. (S2) information credibility and trustworthiness: information are safeguarded against their lost or alteration by the unapproved substances.

iii. (S3) verification: evidence that an association is laid out with a validated substance or admittance to administrations is conceded exclusively to confirmed element.

iv. (S4) non-disavowal: confirmation that an information is endorsed by a specific element (substance can't

deny this activity).

v. (S5) responsibility: a client ought to have explicit obligations.

2.1.1.3 Security Threats

1. **Wireless Sensor Network (WSNs)**: WSNs are effectively inclined to IoT security assaults because of the transmission medium utilized for broadcasting. A portion of the major WSN dangers are:

a. Physical Assaults: A sensor gadget should be executed in each item to accomplish their full capacity. In any case, it is hard to actually safeguard the gadgets as well as to stop unapproved actual access. A programmer can make changes to the accessible information of a hub/sensor, hence prompting the working of the entire sensor organization to be in danger.

b. Node Replication: In this assault, a current hub identifier of a sensor is duplicated to the very network as another sensor that would prompt duplication causing misrouting of bundles, recording of bogus sensor readings, or an organization separation consequently upsetting a sensor organization's exhibition.

c. Selective Sending: In WSN, it is expected that all hubs get messages to the objective. A malignant hub specifically advances bundles in this assault. It might basically drop specific messages without sending them. It is hard to recognize the aggressor as they will generally change bundles which begin from a couple of explicit hubs and the message is then sent to different hubs in this way restricting the doubt of the noxious hub's changes.

d. Wormhole Assault: It is a basic assault where the assailant records parcels at a few area in the organization and afterward burrows them to an alternate area. This cycle can be completed specifically. Additionally, while steering control messages are burrowed, routine might be disturbed/

e. Sybil Assault: This assault was presented with regards to shared networks. It happens when a PC is captured and the programmer guarantees numerous characters and an enemy can figure out how to be at more than each spot in turn. A solitary hub presents numerous characters in the organization which prompts critical decrease of viability of adaptation to non-critical failure like conveyed stockpiling,

dissimilarity and multipath.

f. Sinkhole Assault: An interloper assumes control over a hub inside the organization and attempts to draw in all the rush hour gridlock from neighbor hubs. This interaction can be done with the utilization of the directing calculation and drawing in different hubs. The foe dispatches numerous extreme assaults including sending the bundles specifically, alteration of messages or erasing the parcels.

g. Service Assault forswearing or Refusal of administration assault: Administrations are made inaccessible to authentic clients and the connections of casualty are obliterated by flooding them with genuine like solicitations from the assailant, in this way prompting disavowal of the relative multitude of administrations sent by authentic clients.

h. Eavesdropping: The gatecrasher pays attention to the data during information transmission between the two hubs over an organization. Data continues as before yet its protection is compromised. The interloper can utilize this data against the client.

2. Radio Recurrence Recognizable proof (RFID):

A few sorts of assaults against RFID innovation are as per the following:

a. Physical Information Alteration: Labels are genuinely gotten by the aggressor and afterward information is changed. Shortcoming enlistment is utilized to change an actual information. Shortcoming enlistment is a course of changing information when it is composed or handled and can be performed utilizing laser cutting magnifying lens or little charged needle prompting crisscross between the information put away on the labels and the items to which these labels are joined. A RFID tag joined to a fabricated item gives inaccurate data about the thing. The label recognizability lessens because of this assault (Smith et al., 2021).

b. Tag Cloning: The first tag is supplanted with another one and the first label identifier (id) is replicated to it. On the off chance that there is no actual access security for the RFID labels, the assailant can undoubtedly supplant the first tag with another one.

c. Tag Trading: A well known assault where the labels of two distinct items are supplanted. It happens in retail locations where a costly tag is traded with a low-evaluated tag so the expensive item is bought at a lesser rate.

d. Denial of Administration Assault: When a data is mentioned from a tag by the RFID peruser, it

gets the recognizable proof id of the tag and afterward contrasts it and the id put away in its data set. Both RFID peruser and server data set are powerless against DoS assault, accordingly when this assault happens, the tag neglects to send its character to the peruser. Subsequently, the association between the tag and the peruser won't be steady and thus will prompt help interference a review.

2.1.1.4 Solutions For Security Dangers

1. Security answers for Remote Sensor Organizations (WSNs)

A portion of the arrangements viewing remote sensor networks are as per the following:

a. Shared Keys: A security highlight which will in general get a gigantic arrangement of focus in WSNs is the key administration region. WSNs are viewed as remarkable in this trademark because of their size, portability and power requirements. Generally, utilizing one of the numerous public-key conventions prompts the culmination of key foundation. As a rule by applying a straightforward key foundation, security against pariah assaults is taken consideration for any organization. Nonetheless, it is realized that a worldwide key gives no organization strength, and pairwise keys are not a versatile arrangement.

b. Protected Gathering: WSN comprises of an enormous number of little hubs which are smaller and mechanized gadgets. Sensor hubs are expected to tie the hubs together. For finishing a specific job, the gathering individuals should have the option to safely speak with one another, despite the fact that general security may likewise be being used. Special cases for the arrangements are made when all the more remarkable hubs are accountable for safeguarding the individual from static gatherings.

c. Encryption: Sensor networks generally run in broad daylight or wild regions over intrinsically unconfident remote channels. Consequently, it is immaterial for a gadget to listen in or even add messages into the organization. The customary approach to taking care of this issue are to embrace strategies, for example,

message verification codes, symmetric key encryption plans and public key cryptography.

d. Secure Information Conglomeration: Sensor organizations and information collection strategies will generally be powerless towards a scope of assaults including refusal of administration assaults. The main difficulty in networks is information traffic which is caused because of the expansion in information moves. To diminish the above cost and organization traffic, sensor hubs total estimations prior to sending them to the base station. This kind of information charms an assailant. The validity of the created

information will be impacted in the event that a foe has command over a conglomerating hub and decides to disregard the report or delivers a misleading report. Thus, the organization overall should be thought of. The primary point in this space is to utilize versatile capabilities that will have the option to find and report manufactured reports through exhibiting the validness of information some way or another. Notwithstanding, an improvement in this space might be as yet required, for example, measure of information, which is created by intuitive calculation.

e. SPINS, Security Conventions for Sensor Organizations: Twists are enhanced for asset obliged conditions and Remote correspondence. Turns have a few structure blocks because of which it offers numerous security properties like information confirmation, information newness, semantic security, low correspondence above, and replay insurance.

f. TinySec: Connection Layer Security Design: TinySec can be incorporated into sensor network applications as they are lightweight and have an overall security bundle, thus it is remembered for the authority TinyOS discharge. The two extraordinary security choices that TinySec upholds are, validated encryption (TinySecAE) and confirmation just (TinySecAuth). With verified encryption, TinySec encodes the information payload and validates the bundle with a Macintosh. During the verification just mode, TinySec validates the whole parcel with a Macintosh, yet the information Payload isn't scrambled.

B. Security answers for Radio Recurrence Distinguishing proof (RFID)

1. Physical technique

a. Kill tag: The guideline utilized for this strategy is crippling the label's capability to quit following the tag and its transporter, this is generally finished in a grocery store. The upside of kill order is tag losing. For instance, the label's data will be of no utilization once a thing is sold. It isn't advantageous for post-deal administration and further comprehension of the item.

b. Moreover, on the off chance that the kill recognizable proof number (PIN) is uncovered, an individual with an evil aim might take from the store.

c. Faraday net: As per the electromagnetic field hypothesis, a holder comprised of Faraday net conductive material can not enter Faraday net external a radio wave as well as the other way around. By putting a label inside a holder comprised of conductive material probably keeps the tag from being examined, for example a uninvolved tag can't get a sign and a drive tag can't convey a message out. Hence,

utilizing the guideline of Faraday net can keep security gatecrasher from checking a label's data. For instance, assuming a coin is embedded in a RFID tag, by utilizing the rule of Faraday net one can keep a security gatecrasher from examining it so nobody becomes acquainted with how much in the client's tote.

d. Stopping tag: The guideline behind the utilization of a unique halting tag is to obstruct hostile to impact calculation which implies that similar reaction information is shipped off the peruser so the tag is secured.

2. RFID security convention

The product security instrument in view of mystery code strategy are more invited by clients rather than the equipment security systems that depend on actual techniques. Albeit as of late numerous RFID security conventions have been proposed, the vast majority of them have different disadvantages.

In 2003, a lightweight label confirmation convention was proposed by Vajda and so on. An adjusting arrangement adjusts among execution and security. The aggressor might have the option to reveal the convention assuming he possesses abundant figuring assets. Sarma and so forth proposed a Hash-Lock convention which utilizes the metaID to supplant the genuine label ID with the goal that data doesn't get followed or spilled. Nonetheless, an ID dynamic invigorating system is absent. The metaID is kept steady and no progressions are made to it. Also, the ID is sent by plain message through a perilous channel. In this manner, almost certainly, the convention may be gone after by a phony name or retransmit. Weis and so forth proposed an irregular Hash-Lock convention which utilizes a question reaction instrument in light of irregular numbers. The label ID passed verification is sent by plain message through a risky channel. In this way, the convention is likewise prone to be gone after by counterfeit name or re-send, and followed. As the information volume that is moved between the tag and peruser is enormous, the application prospect isn't excessively perfect (Smith et al., 2021).

Su et al., (2018) proposed a LCAP convention which likewise is a question reaction type convention. The label ID is powerfully invigorated after every activity. The convention just necessities two discrete estimations. The

intricacy of the calculation is diminished as it cuts the ID into two sections, i.e., left and right. As it comprises just of label ID and one directional Hash capability, it very well meets the minimal expense necessity of the RFID framework. Since the label ID is sent provided that it passes validation, and is invigorated after every activity, then, at that point, the LCAP convention can really forestall following and data spillage. Label ID is revived in the wake of getting the ID update message and the message having passed verification upon the end of each discussion. Upon this time, foundation data set has previously refreshed the important ID. In spite of the fact that LCAP convention is a palatable confirmation convention for minimal expense RFID framework, it isn't good for general processing climate for circulated data set, as data set synchronization is a potential security stowed away

risk.

2.1.1.4 Privacy Dangers

A. Identification

Distinguishing proof indicates the danger of interfacing a (relentless) identifier, like the location and name or a nom de plume any sort, with an individual and data about him. The danger lies in associating a personality to a particular security, disregarding setting and it likewise enacts and works with different dangers. For example, profiling and following of people or assortment of various information sources. The danger of distinguishing proof is as of now most predominant in the data handling stage at the backend administrations, where tremendous measures of information is gathered in a focal spot beyond the subject's control.

The primary test looked in distinguishing proof is the plan of IoT frameworks which favor neighborhood over brought together handling, even over vertical collaborations, to such an extent that a base measure of recognizing information is accessible external the individual circle of a client.

B. Localization and Following

Confinement and following signify the danger of deciding and recording a singular's area through reality. Following necessities distinguishing proof to tie nonstop limitations to one individual (Smith et al., 2021). By and by, following is conceivable through various means, for example, web traffic, GPS, or phone area. The majority of the substantial protection infringement have been recognized connected with this danger, for example GPS following, divulgence of private data, or for the most part the sensation of being followed. In the prompt actual closeness, limitation and following generally doesn't prompt security infringement, for example, anybody in the quick encompassing can straightforwardly notice the subject's area. Confinement and following consequently shows up as a danger mostly in the period of data handling when areas follows are worked at back closes beyond the subject's reach. The principal challenges looked in

confinement and following is the attention to following despite latent data focus, control of shared area information in indoor conditions, and protection safeguarding conventions for correspondence with IoT frameworks.

C. Profiling

Profiling means the danger of gathering or orchestrating data dossiers about people to find interests by connection with different profiles and information. The strategies for profiling techniques are for the most part utilized for personalization in web based business (recommender frameworks, pamphlets and commercials) yet in addition for inside advancement in light of client socioeconomics and interests. Models where profiling is directed to an infringement of protection infringement are cost separation, spontaneous notices, social designing, or mistaken programmed choices, for example by Facebook programmed identification of sexual wrongdoers. Gathering and selling profiles about individuals is generally seen as a security infringement. These models show that the profiling

danger shows up primarily in the scattering stage, towards outsiders, yet additionally towards the actual subject in type of mistaken or segregating choices. These methodologies can be applied to IoT situations yet ought to be adjusted from the typical model that accepts a focal data set and record for the many disseminated information sources which are normal in the IoT. This requires impressive endeavors for recalibration of measurements and overhaul of calculations, as for example late work in differential security for disseminated information sources shows. Information assortment is one of the essential commitments of the IoT and a primary driver for its acknowledgment. In this manner, it is viewed as the greatest test in adjusting the interests of organizations for profiling and information examination with person's security prerequisites.

D. Privacy abusing association and show

In this danger, individual subtleties are conveyed through a public medium and afterward is uncovered to unfortunate people. Various IoT applications, for example, the assembling, framework, clinical and medical services frameworks and so on need proliferating associations inside the client. In these frameworks, it is possible that the subtleties are furnished to the clients with the assistance of the usage of brilliant things in the environmental factors. For example, through moving toward lighting strategies and TV or work area screens showing recordings. Alternately, clients rule frameworks in an option natural system with the usage of brilliant things in the climate (like inclination and conveying shrewd articles). All things considered, various intercommunications and it are naturally open to coordinate strategies. This hence makes a reason to security issues when restricted intel is traded between the client and the framework. For example, in

savvy urban communities, an individual might scrutinize the course to a particular emergency clinic. Such an enquiry ought not be answered back, (for example, showing the course on a public street can be seen by any individual who passes by a similar street) (Smith et al., 2021).

E. Lifecycle advances

Security is threatened when savvy objects uncover their mystery subtleties all through the adjustment of overseeing areas in their lifecycle. This issue is seen as for the sabotaging pictures and recordings that are typically seen on cameras and other new gadgets too. Since security contraversions from life cycle are principally because of the assembled data, this relies upon the data level of the IoT reference model. The existence pattern of numerous client care items is even currently planned as purchasing the item for once constantly and the outcomes have not yet advanced. Brilliant items can credit for a really captivating life cycle that will incorporate exchanging, loaning, giving and arranging invaluably. Thusly, Analyst perceive the requirements for versatile outcomes that will plainly comprise a few issues. Some life cycle changes, (for example, sharing a savvy object needs securing secret subtleties at an impermanent stage). The mystery subtleties can be loosened and the genuine proprietor can seek after utilizing the gadget reliably.

F. Inventory assault

This is characterized as the uncertified assembling of information in regards to the truth and elements of individual gadgets. Interconnection of IoT gadgets is considered as one significant developing component of IoT. Shrewd items are viewed as inquirable over the Web with the recognizable proof of all the web conventions. Approved associations can question things from everywhere (like the ensured framework clients and proprietors) though the non-approved associations can inquiry and break this to orchestrate an itemized record of things at a specific region, (for example, a place of business, public institutional spots, modern region and so on.). Despite the fact that savvy items can undoubtedly decide approved and non-approved associations, a unique finger impression of these associations transmission rate and other uncommon determinations could be used to recognize their classification and portrayal. With the expected heightening of WSNs innovation, fingerprinting methods could likewise be displayed quietly (like a mysterious audience in the region of a casualty's home).

For baffling the stock assaults in IoT, Analyst recognize the two specific issues as follows: Above all else, brilliant article ought to be empowered to approve enquiries and answer those questions by approved associations to disappoint coordinated stock assaults. Second of all, systems that shield the health against fingerprinting will be approached to safeguard and forestall latent stock assaults in light of the transmission finger impression of a brilliant item.

G. Linkage

In this danger, previously separate framework gadgets are associated together, (for example, the social occasion of data connected with various information are unveiled which were never uncovered to the previously dark sources). The clients are uninformed about the prevalent assessment and information lost when every one of the various information and

An equal interconnection, first and foremost, will at last interface frameworks from various associations to create an enhanced framework that provisions new administrations which no single framework at any point gave all alone. Furthermore, a prosperous interconnection of such thing will continuously require a coordinated trade of data and upkeep between various people.

2.1.1.4 Privacy Protecting Arrangements

A few methodologies have been proposed for tending to the protection concerns and security contemplations of specialist organizations:

A. Cryptographic procedures and data control

However specialists have spent a ton of years in proposing an original protection saving plans, cryptography is as yet the most predominant one in practically the ongoing proposed arrangements in general, despite the fact that, for the majority of the snags confronted, a large number of the sensors can't offer satisfactory security conventions

because of the restricted measure of capacity and calculation assets.

B. Privacy mindfulness or setting mindfulness

Answers for security mindfulness have been essentially centered around the utilizations of people which give a fundamental protection attention to their clients that shrewd gadgets, like wearable wellness gadgets, brilliant televisions, and wellbeing screen frameworks could gather individual information about them. For instance, in ongoing examination, a system called SeCoMan was proposed to act as a believed outsider for the clients as applications probably won't be entrusted enough with the area data that is made due.

C. Access control

Access control is one of the feasible arrangements utilized in mix to encryption and security mindfulness. This enables clients to deal with their own information. An example of this approach is CapBAC, proposed by Skarmeta, Hernandez, and Moreno. It is basically a conveyed approach in which brilliant things themselves are permitted to settle on approval choices.

D. Data minimization

The standard of information minimization implies that the IoT specialist co-ops ought to restrict or lessen the grouping of individual information to what is straightforwardly pertinent. They ought to likewise keep the information just however long it is expected to satisfy the reason for the administrations given by the innovation. There are other recommended arrangements that don't fall into the past four classifications, for example, bumming a ride. This is another way to deal with guarantee the namelessness of clients who give their areas. Bumming a ride applications handle areas as the element of interest. As the information on who is at a specific area is superfluous, the constancy compromise is taken out.

2.1.1.5 IoT Weaknesses

Weaknesses are blemishes in frameworks or ventures that permit unlawful clients to give guidelines, access unapproved information or perform forswearing of administration assaults. Weaknesses are available in different region of the IoT framework. This can be in equipment or programming, framework shortcomings and strategies utilized by the framework or clients of the actual framework.

Neshenko et al., (2019) proposed nine IoT weakness classes. These classes incorporate;

i. Deficient actual security
ii. Insufficient energy gathering
iii. Inadequate confirmation
iv. Improper encryption

v. Unnecessary open ports

vi. Insufficient access control

vii. Improper fix the executives capacities

viii. Weak programming rehearses

ix. Insufficient review systems

Notwithstanding, the creators reasoned that most IoT assaults are conceivable as a result of two principal weaknesses in IoT, that is to say, pointlessly open ports, and frail programming rehearses combined with ill-advised programming update capacities. They further point out that lacking IoT access controls and review systems empower assailants to produce IoT-driven malignant exercises in a profoundly secretive way.

Granjal et al., (2017) performed thorough investigation on the security conventions and components accessible to safeguard interchanges on the IoT organizations. They zeroed in on weaknesses and assaults focusing on the IoT organizations. They additionally featured on continuous work pointed toward getting those conventions. The creators distinguished some security challenges at every one of the layers. At the actual layer, conventions don't determine a key model (i.e., a model for creating, dispersing, putting away, and supplanting cryptographic keys), since it relies to a great extent upon the assets accessible on the IoT gadgets to help key administration tasks. At the organization layer, directing conventions (e.g., Steering Convention for Low-Power and Lossy Organizations or RPL) offer protection from outside assaults just, and are not versatile against inside assaults. Lastly, at the application layer, conventions (e.g., Compelled Application Convention or CoAP) need suitable key administration instruments for multicast correspondence.

Celik et al. (2019), concentrated on protection and security issues connected with IoT program investigation. They dissected various frameworks for five significant IoT programming stages (Samsung's SmartThings, OpenHAB, Apple's HomeKit, Google's Android Things, and Amazon AWS IoT). That's what the creators presumed:

i. The predominant IoT programming stages structure their applications around a sensor-calculation actuator saying.

ii. A set-up of investigation apparatuses and calculations focused on at assorted IoT stages is as of now to a great extent missing

iii. Because IoT applications control actual cycles through gadgets, security and protection issues are more unpretentious and challenging to distinguish than in related fields

iv. Most approaches come up short on examination responsive qualities like way and setting awareness

v. Most approaches frequently don't consider security and wellbeing issues in multi-application conditions and through data streams in trigger-activity stages

vi. Members of the examination local area frequently utilize the SmartThings stage to assess their devices, as various open-source official and outsider applications are accessible; and

vii. IoT frameworks frequently execute calculations on the Theoretical Punctuation Tree (AST) of a SmartThings application in light of the imperatives on Sweet language and restrictive back-end libraries.

In 2018, The Open Web Application Security Venture (OWASP) refreshed its main ten IoT weaknesses. The rundown incorporates:

1. Weak, guessable, or hardcoded passwords
2. Insecure organization administrations
3. Insecure biological system interfaces
4. Lack of secure update instrument
5. Use of uncertain or obsolete parts
6. Insufficient security assurance
7. Insecure information move and capacity
8. Lack of gadget the executives
9. Insecure default settings
10. Lack of actual solidifying.

The OWASP project is expected to urge and help producers to assemble their gadgets in view of safety and hence make their gadgets secure by plan. Its will probably assist associations and people with measuring the adequate gamble and make proper moves to alleviate them. The OWASP top 10 IoT rundown of weaknesses doesn't accompany separate rules for different partners yet rather adopts a brought together strategy to address IoT weaknesses that may be influencing IoT gadgets. The OWASP IoT top 10 venture group kept away from explicit IoT security weakness rules. This study considers and talks about the accompanying key weaknesses which represent the most noteworthy security dangers to IoT environment:

a. Weak qualifications and absence of solid validation instruments

In 2010, Cui et al. (2020) directed Web scale testing and uncovered the greater part 1,000,000 implanted gadgets with default qualifications. The greater part of these gadgets had a place with government associations, huge ventures, Network access Suppliers (ISPs), and instructive establishments. After two years, in 2012, the Carna botnet uncovered that there were more than 1.2 million gadgets online with no or default certifications.

a. b. Open Ports

A main pressing issue to the security of IoT networks is the critical number of gadgets with superfluously open ports. Czyz et al. (2020) showed that countless IoT gadgets are just reachable over IPv6, and different IoT conventions are more available over IPv6 than over IPv4 (e.g., 6LoWPAN). They found that a given IPv6 port is quite often more open than a similar port is in IPv4. For instance, IPv6 had 5% more open SSH ports, and 46% more open Telnet ports when contrasted with IPv4. They likewise presumed that there was a fundamental disappointment in associations to convey predictable security strategies for their gadgets in accordance with port obstructing. In conclusion, the creators exposed the conviction that the security danger of open ports in IPv6 is hosed because of the infeasibility of IPv6 far reaching filtering by finding high-esteem has through checking alone.

c. Weak programming rehearses

Albeit solid programming rehearses and infusing security parts could expand the versatility of the IoT, numerous analysts have revealed that endless firmware are delivered with referred to weaknesses, for example, secondary passages, root clients as prime passageways, and the absence of Secure Attachment Layer (SSL) use. Thus, an enemy could without much of a stretch endeavor known security shortcomings to cause cradle spills over, data changes, or gain unapproved admittance to the gadget (Smith et al., 2021).

d. Data Spillage

IoT applications are likewise inclined to information spillage weaknesses. Celik et al. (2018) directed static pollutant examination on 230 SmartThings applications, and viewed that as 138 of the applications uncovered somewhere around one piece of touchy information through the Web or informing administrations. Besides, the creators showed that portion of the dissected applications spill somewhere around three different delicate information sources, for example, gadget data, gadgets state, client input, and so on, to the Web or informing administrations.

e. Improper encryption

While obviously encryption can assist with tending to a portion of the weaknesses introduced in (Smith et al., 2021), complex cryptographic capabilities, like those tracked down in the High level Encryption Standard (AES), can bring about huge above for asset compelled IoT gadgets. Subsequently, there is a developing interest in super lightweight, however secure encryption calculations streamlined for low-controlled equipment. Nonetheless, as Singh et al., (2020) brought up, equipment based encryption motors have a critical weakness: the power dispersal of the equipment can be estimated while performing encryption, and later genuinely broke down to recuperate the mystery key, hence compromising the gadget. Numerous countermeasures have been proposed to address this weakness in AES motors. Sadly,

these countermeasures bring about huge power and execution overheads, and hence are not appropriate for lightweight cryptographic natives.

The evaluated writing has uncovered a few deficiencies that this paper addresses. For example, this paper tended to the whole range of the recorded IoT security concerns (recognizable proof, verification, information respectability, trust, information secrecy, access control, information protection and information accessibility) in contrast to the current papers. It is just Riahi et al. that covered seven out of eight security concerns leaving out information accessibility. Besides, this paper completely covered the IoT security necessities though the current papers to some extent covered this under protection, personality the board and trust the executives. Thirdly, Specialist analyzed the weaknesses in IoT, yet figured out that the greater part of the current papers zeroed in on only a couple of explicit regions, for example, equipment or programming, framework shortcomings and strategies utilized by the framework

or on the other hand clients of the actual framework. This was additionally not quite so extensive as has been enunciated in this paper. At long last, contrasted with existing works, this paper draws out the mix of protection and security through the proposed danger scientific classification that is introduced.

2.1.1.4 Countermeasures

Carrying clients into the crease requires creators and designers to comprehend that clients hold the possibility to be proficient and educated about the components regarding a framework. Taking into account clients and the different collaborations they have with the framework can permit planners to have an all the more balanced way to deal with understanding and guaranteeing IoT security (Smith et al., 2021). To feature the job clients can play in safeguarding their security and limiting their gamble, Specialist examine steps that can be taken well before a cyberattack really occurs and what should be possible while a hacking endeavor happens. Pursuing guaranteeing clients' protection and security ought to start by thinking about what clients resemble before they start to utilize an IoT gadget. Architects and engineers ought to assess, among different elements, clients' opinion on their wellbeing, their inspiration to be proactive in getting their data, and the trust they have in interconnected gadgets, as these variables will influence how clients communicate with their gadgets. For example, the typical client comes up short on sufficient comprehension of the number and sort of Web related dangers to which the person in question may be uncovering oneself and the job the individual in question can play in getting their data. This present circumstance can be improved; an expanded consciousness of security dangers and dangers is associated with the quantity of defensive moves clients report having made. This study present beneath, the

countermeasures that incorporate access and validation controls, security conventions, interruption recognition, single sign-on, laying out trust, security mindfulness, protection by plan, and security devices:

Access and Validation Controls

Access and approval systems are basic for the reception of IoT innovation. Subsequently, frameworks admittance to approved demands should be considered while creating IoT frameworks. Approvals procedures should confirm in the event that two items partook in correspondence have been approved. The most well-known verification strategies are a job based admittance control (RBAC) and a property based admittance control (ABAC). ABAC changes honors over completely to a bunch of qualities relegated to an item, though RBAC switches honors over completely to a bunch of jobs doled out to an article. One more method which can be utilized to guarantee approval for IoT objects is known as Validation and Approval for Obliged Conditions (Pro).

Martı'nez et al., (2019) proposed SMARTIE, a coordinating client driven stage for productive yet secure spread of IoT information in shrewd urban areas. The creators' given bits of knowledge into the use of the IoT-ARM to produce this stage. The principal objective of this stage is to enable clients to assume command over their entrance control and protection inclinations to administer gadgets. The SMARTIE that depends on the IoT-ARM rules on security and adaptability gives building curios that empower effectively and proficiently upholding client access control arrangements. The proposed integrative methodology is planned to give a client made due, adaptable, and versatile component for access control to safeguard the admittance to brilliant meters' information using the SMARTIE stage. Notwithstanding oversee data, the fundamental objective of this stage is to engage clients with full control on their gadgets through a strategy based approach.

He et al., (2019) in their investigation of access control and confirmation in the home IoT noticed that the ongoing verification strategies for the home IoT seem relocated from cell phone and work area standards, which generally, expect a solitary client for every gadget climate. Through their web-based client study, they found significant contrasts in the members' ideal access-control strategies for various capacities inside a solitary gadget (e.g., refreshing programming, turning lights on/off, turning cameras on/off, adding new client, and so on), as well as founded on who is attempting to utilize that capacity (e.g., companion, teen, youngster, seeing family, sitter, neighbor, and so on) they had the option to pinpoint different context oriented factors (e.g., season of day, area of client, area of gadget, who is close by, and so on) that, alongside abilities and connections, direct the particular of more mind boggling, yet wanted,

access-control arrangements.

Zeng and Roesner (2021) utilized the entrance control arrangements got from, among other plan standards from different examinations, to make an entrance control framework for the shrewd home. The application included four sorts of access controls:

- Job Based Admittance Control: Every client is relegated a job — administrator, youngster, or visitor. Just administrators are permitted to change access control strategies, add new clients, and arrange the gadgets.
- Area Based Admittance Control: Clients can be limited from utilizing gadgets on the off chance that they are not actually close to the gadget.
- Administrative Access Control: Permits a client who might be limited from utilizing a gadget, to utilize the gadget, if and provided that another (approved) client is close by.
- Responsive Access Control: On the off chance that a client endeavors to utilize a gadget they don't have consent to utilize, the application will ask a more favored client for consent progressively, by sending a warning requesting that they endorse or deny the solicitation.

For their work, the creators underscored that the plan of safety and security highlights for a shrewd home should not restrict a client's essential use case for the brilliant home. To them, the client's on the whole correct to utilize the administrations is vital.

Yang et al., (2018) proposed RFID-based answers for address explicit IoT security issues like gadget confirmation, gadget protection, and organization joining. The chance of a gadget being taken, lost or harmed made the possibility of joining a RFID tag to an IoT gadget chip alluring. Their answer involves an interesting arrangement of labels and gadget identifier, a meeting key, and a power way. Guaranteeing a free from any potential harm conveyance platform is planned. In the mean time, Fernandes et al., (2018) proposed a strategy for limiting admittance to IoT delicate information. The creators have made a framework called FlowFence that permits projects to control the utilization of information. The specialists accomplished this by getting to delicate information by hindering the progression of information recognized by the client. The proposed arrangement permits software engineers to partition the program into two modules. The main module oversees delicate IoT information in a test climate, while the second purposes respectability requirements to facilitate the transmission of such touchy information. An outline of FlowFence by IoT clients has shown that information capacity is limited with restricted development.

Le and Mutka (2019) proposed a lightweight approval convention that permits a client to

effectively move his/her entrance freedoms to shrewd home gadgets for the purpose of handling the issue of designating consents. The convention works by moving access privileges to a gadget as a Sprout channel with the assistance of gotten hashing to keep the consent from being fashioned. The Blossom channels keeps things from being eliminated and subsequently, a client can't reproduce a consent higher than whatever he/she is keeping yet can in any case move lower authorizations to different clients.

Late investigations have zeroed in on validation systems that for the most part manage biometric factors. For instance, many papers created remarkable touch-based verification instruments for wearable or savvy home gadgets. On the other hand, introduced a ceaseless validation framework in light of mathematical and non-volitional elements of heart movement.

Feng et al., (2019) introduced VAuth, the main framework that Analyst found that gives constant verification system to voice collaborators. VAuth gathers the body-surface vibrations of a client and coordinates it with the discourse signal got by the voice colleague's receiver. VAuth can fit inside things that individuals typically wear, like eyeglasses, headphones, and neckbands, Such a framework can ensure that the voice partner just executes the orders that start from the voices of approved clients. The creators assessed the framework on 18 clients and 30 voice orders, and accomplished a location

precision of 97% with under 0.1% misleading up-sides, no matter what VAuth's situation on the client's body, the client's language, the client's inflection, or the client's versatility.

Security Conventions

A security convention to help information trade among objects was proposed by (Li et al., 2020) and joined with a security structure for improving security, trust, and protection for implanted frameworks. Lightweight symmetric encryption and uneven encryption in Unimportant Record Move Convention (TFTP) were proposed to make the given convention suitable to the obliged idea of IoT gadgets. In (Li et al., 2020), the creators propose systems to guarantee security at the organization layer and at the application layer and play out a trial study to recognize the most suitable secure correspondence component for current detecting stages.

Li et al., (2020) proposed a without key specialized strategy for IoT organizations, which they called HlcAuth. Basically, HlcAuth used challenge-reaction instruments for common verification between the entryways and savvy gadgets without key administration. Through true assessment, the creators

demonstrated the way that HlcAuth can shield against replay assaults, message-fabrication assaults, and man-in-the-center assaults. In any case, for HlcAuth to work, the creators expected that aggressors are not inside a specific reach (no less than 4.2 meters) of the entryway hub.

Xie and Wang (2019) proposed work of equipment based Actual Unclonable Capabilities (PUFs), to improve and empower security-related tasks to be taken care of at the sensor level in IoT. Use of PUFs will assist in expanding the security with evening out of the IoT, by permitting low-level security executions on the things and furthermore by formulating cryptography programming to perform unique errands like check.

Single Sign-On

In specific IoT settings, single-sign-on (SSO) systems can be valuable, since clients need to verify just a single time to collaborate with different gadgets. Clients can then get to all assets for which they approach authorization without entering numerous passwords. Be that as it may, customary Web 2.0 SSO, for example, OpenID and Custom were not intended to satisfy specific IoT necessities, for example, giving the client command over the decision of personality supplier. Different systems force clients to utilize a specific convention, which can be risky in a heterogeneous climate. Another issue is the absence of help for directional personalities, wherein objects broadcast their characters.

Laying out Trust

Trust is crucial for carry out the IoT. It envelops how clients feel while cooperating in the IoT. Sensations of defenselessness and being under some obscure outside control can enormously sabotage the sending of IoT-based applications and administrations. There should be support for controlling the condition of the virtual world. Clients should have the option to control their own administrations, and they should have instruments that precisely portray every one of their cooperations so they can shape an exact mental guide of their virtual environmental elements. Since, gadgets in IoT can genuinely move starting with one proprietor then onto the next, trust ought to be laid out between the two proprietors to empower a smooth change of the IoT gadget regarding access control and consents. Xie and Wang (2019) introduced the idea of shared trust for between framework security in IoT by making a thing level access-control system. It lays out trust from creation to activity and the IoT transmission stage. This trust is laid out by two instruments; the creation key and the token. Any new gadget which is made is doled out a

creation key by a privilege framework. The gadget producer should demand for this key. The token is produced by the producer or current proprietor, and this token is joined with the RFID ID of the gadget. This system guarantees that the consents are changed by a similar gadget assuming that another proprietor is delegated, or it will be utilized in an alternate branch of a similar organization, consequently diminishing the overheads of the new proprietor. Proprietors can change these tokens, gave the past token is benefited, to supplant consents and access control to the past token.

As well as empowering risk mindfulness, creators of IoT gadgets ought to zero in on imparting trust among clients (2019). All gadgets ought to have the option to carry out their fundamental roles dependably, however on account of brilliant, interconnect gadgets, clients ought to be guaranteed that their data will be dealt with appropriately and that they will can renounce admittance to this data whenever. IoT gadgets are planned explicitly to work with a lot of clients' information, so a decrease in admittance to clients' data can be counterproductive to the general objectives of an IoT gadget. Thusly, consoling clients about their gadget's safety is significant. Reassuring clients might include including a specific degree of straightforwardness with respect to what steps are being taken to safeguard their own data. Expanding generally speaking degrees of trust might lead clients to be more disposed to permit IoT gadgets admittance to data they probably won't allow admittance to assuming there were questions about the security abilities of the IoT framework.

Security Mindfulness

Another significant safety effort for the achievement and development of the IoT structure is mindfulness among human clients who are essential for the IoT. In Hopeman et al., (2019) the creators made sense of the outcomes of not ensuring IoT utilizing genuine numbers. They got to the IoT gadgets (SCADA

gadgets, web cameras, traffic regulators, and printers) that were freely accessible utilizing the default secret word or without a secret word. The recorded outcomes showed that a considerable lot of these gadgets were really open. Assuming individuals kept on overlooking security and utilize negligible security like the default secret key that accompanies the item, this might prompt more damage than anything else. Programmers can go after the whole organization assuming that one of the gadgets is unprotected.

Security Devices

Past preparation, clients can be outfitted with instruments that assist them with deciding the wellbeing of an IoT gadget. Specialists have proposed a portable application that upholds clients' protection related choices (Smith et al., 2021). A "security mentor" as a portable application can illuminate clients on the off chance that a RFID protection strategy coordinates with their favored security settings. In general, these sorts of apparatuses may make clients more mindful of their job in the framework and what can be generally anticipated for their protection.

Protection by plan

One reasonable arrangement is security by plan, in which clients would have the apparatuses they need to deal with their own information. The arrangement is somewhat close from current reality. At the point when clients produce an information part, they can as of now utilize dynamic assent devices that grant specific administrations to access as close to nothing or as a lot of that information as wanted.

2.1.2 Random Forest

Irregular Woods (RF) is a strong gathering learning strategy that is broadly utilized for characterization and relapse errands. It depends on choice trees, where different trees are fabricated and consolidated to further develop precision and forestall overfitting. Proposed by Leo Breiman in 2001, Irregular Backwoods is perceived for its straightforwardness, power, and capacity to deal with huge datasets with higher dimensionality and missing information.

2.1.2.1 Key Ideas of Arbitrary Woodland

1. Decision Trees: At its center, Arbitrary Woodland comprises of various choice trees, every one of which pursues choices in light of highlights of the information. A choice tree is a various leveled model where choices are produced using a root hub to a leaf hub. Each split of the not entirely set in stone by an element and an edge that ideally partitions the information to limit grouping mistake or lessen difference in relapse errands.
2. Bootstrap Conglomerating (Packing): Irregular Backwoods is fabricated utilizing a strategy called bootstrapping, or stowing, which is a technique that works on model exactness via preparing various powerless students (choice trees) on various subsets of the preparation information. Every choice tree is prepared

on a haphazardly chosen subset (with substitution) of the information. The last expectation is a total of the forecasts made by all trees in the woodland. For arrangement, larger part casting a ballot is utilized, while in relapse, the normal of the trees' expectations is taken.

3. Feature Randomization: A vital development in Irregular Woods is that it presents haphazardness in testing the information as well as in choosing the elements used to divide hubs inside individual trees. Rather than thinking about all elements at every hub, Irregular Woodland chooses an irregular subset of highlights. This diminishes the relationship among's trees and works on the general execution of the model by bringing down change without expanding predisposition.

4. Ensemble Learning: Irregular Woodland has a place with the group of troupe strategies, and that implies that it constructs numerous models (for this situation, choice trees) and totals their outcomes. Thusly, Irregular Woods mitigates overfitting, a typical issue with choice trees, where models might turn out to be excessively intended for the preparation information and neglect to sum up well to concealed information.

5. Out-of-Sack (OOB) Mistake: One of the novel benefits of Irregular Woodland is its utilization of out-of-pack (OOB) tests for blunder assessment. Since each tree is constructed utilizing a bootstrapped test, roughly 33% of the information isn't utilized for preparing every individual tree. These unused data of interest (OOB tests) act as an approval set to gauge the speculation blunder of the model without the requirement for cross-approval.

2.1.2.2 Applications of Irregular Woodland in IoT-based Frameworks

In IoT-based frameworks, where gadgets are interconnected and persistently produce immense measures of information, guaranteeing protection and security is a huge concern. Irregular Timberland is especially appropriate for IoT conditions because of multiple factors:

1. Scalability: RF can productively deal with enormous and complex datasets that are normal in IoT frameworks, where information is gathered from a huge number of sensors and gadgets.

2. Anomaly Recognition: In IoT organizations, security dangers can appear as irregularities. Arbitrary Woodland models have been utilized to distinguish oddities in network traffic or gadget conduct by recognizing designs that stray from the typical information appropriation.

3. Data Protection: Arbitrary Woodland can be coordinated into security safeguarding structures to characterize information without uncovering delicate data. For instance, RF can work with scrambled information utilizing methods, for example, homomorphic encryption, permitting expectations without uncovering the hidden information.

4. Resource-Effective Sending: IoT gadgets frequently work in asset obliged conditions (e.g., low power, restricted memory). Arbitrary Woodland can be upgraded to chip away at such gadgets by decreasing the quantity of trees or restricting the profundity of each tree, making it appropriate for sending anxious gadgets in IoT frameworks.

2.1.2.3 Strengths of Arbitrary Woodland

1. Non-linearity: Arbitrary Woodland models can catch non-straight connections in information, which is valuable while managing complex IoT conditions where cooperations between highlights are not really direct.
2. Interpretability: In spite of the fact that RF is a gathering strategy, it holds a degree of interpretability. The significance of each component can be estimated by taking a gander at the amount it adds to the dynamic interaction across trees.
3. Robustness to Commotion: Arbitrary Woodland is less delicate to clamor in the information because of the averaging system inborn in its plan. This is especially helpful in IoT situations where information might be inclined to commotion because of sensor mistakes or ecological elements.
4. Multi-class Characterization: RF can deal with multi-class grouping issues, which is fundamental for IoT applications like gadget recognizable proof, where the framework needs to order among a wide range of gadget types

.

Irregular Woodland is a flexible and powerful AI calculation with critical benefits for IoT-based frameworks. Its capacity to deal with enormous, uproarious datasets, forestall overfitting, and give a proportion of component significance settles on it an ideal decision for errands like oddity location, grouping, and security improvement in IoT organizations. Mix into frameworks likewise utilize Convolutional Brain Organizations (CNNs) and Backing Vector Models (SVMs) can additionally upgrade the precision and security of such frameworks.

2.1.3 Convolutional Brain Organizations

Convolutional Brain Organizations (CNNs) are a particular class of counterfeit brain networks intended to deal with organized matrix information, like pictures. CNNs are especially viable in catching spatial orders in information by taking advantage of neighborhood designs through convolutional tasks. At first promoted for picture acknowledgment undertakings, CNNs have since been applied across different areas, including PC vision, normal language handling, and, surprisingly, in Web of Things (IoT)- based frameworks where continuous, enormous scope information should be handled.

2.1.2.1 CNN Architecture

The engineering of CNNs is worked around utilizing convolutional channels to extricate significant elements from the info information. A normal CNN engineering comprises of a few key parts:

1. Convolutional Layers: Convolutional layers are the structure blocks of a CNN. A convolutional layer utilizes channels (likewise called parts) to filter the information and produce include maps. These channels go about as identifiers for various elements in the information, like edges or surfaces in a picture. The numerical activity behind this includes sliding the channel across the info lattice, figuring dab items between the channel and the information sub-grid. The outcome is an element map that features the presence of the distinguished highlights. Channels in CNNs are generally a lot more modest than the info yet can catch nearby highlights by utilizing the responsive field, which is the locale of the information that each channel "sees." These elements are then gone through non-straight enactment capabilities like ReLU (Corrected Direct Unit), which brings non-linearity into the model, permitting CNNs to learn complex examples.
2. Pooling Layers: Pooling layers are utilized to downsample the component maps created by convolutional layers. This diminishes the spatial components of the information, making the model all the more computationally effective while safeguarding significant highlights. Max pooling, the most normally utilized pooling technique, chooses the greatest worth inside a window, really holding the main elements while disposing of immaterial subtleties. Pooling assists with accomplishing spatial invariance, implying that the organization turns out to be less delicate to the specific area of highlights in the info information.
3. Fully Associated Layers: After the element extraction and pooling stages, CNNs normally incorporate at least one completely associated (thick) layers. These layers go about as classifiers, where the gained highlights from past layers are joined to make expectations. The contribution to a completely associated layer is a smoothed form of the component maps, and every neuron in the completely associated layer is associated with each result from the first layer. The last layer of a CNN involves a softmax enactment capability to deliver likelihood disseminations for characterization undertakings.
4. Activation Capabilities: The enactment capability in CNNs adds non-linearity to the model, permitting it to learn complex examples. The most widely recognized enactment capability utilized in CNNs is ReLU, which actuates a neuron on the off chance that the result is positive and deactivates it if negative. Other enactment capabilities, as sigmoid and tanh, are additionally utilized, in spite of the fact that they are more uncommon because of issues like evaporating slopes.

5. Dropout: Dropout is a regularization strategy utilized in CNNs to forestall overfitting. During preparing, an irregular subset of neurons is "exited" or overlooked in every emphasis. This powers the organization to turn out to be more vigorous and abstain from over-depending on unambiguous neurons, making the model more summed up.

2.1.2.2 Training Convolutional Brain Organizations

CNNs are normally prepared utilizing the back proliferation calculation joined with an improvement procedure like Stochastic Slope Drop (SGD). The backpropagation calculation works out the inclination of the misfortune capability concerning each weight by repeating in reverse through the layers of the organization. These angles are then used to refresh the loads to limit the misfortune. CNNs can be computationally escalated to prepare, especially as the organization profundity increments, yet propels in equipment, for example, the utilization of Illustrations Handling Units (GPUs), have made enormous scope CNNs doable.

2.1.2.3 Applications of CNNs

1. Image Acknowledgment and Item Recognition

CNNs succeed at picture acknowledgment and item recognition assignments, where the objective is to distinguish articles or examples in a picture. One of the earliest forward leaps in CNNs was their exhibition in the ImageNet rivalry, where models like AlexNet, VGG, and ResNet showed the way that CNNs could essentially beat customary AI calculations on picture characterization undertakings. CNNs have likewise been reached out to protest discovery errands, where the organization figures out how to characterize and confine objects inside a picture.

2. Natural Language Handling (NLP)

However CNNs are generally connected with picture handling, they have likewise been applied to regular language handling errands, for example, message order, sentence demonstrating, and semantic parsing. In these applications, CNNs can catch nearby conditions between words or expressions, making them especially valuable for undertakings like opinion examination or archive characterization.

3. Autonomous Vehicles

CNNs are pivotal in creating independent vehicles, where they are utilized to handle visual contributions from cameras and sensors to distinguish impediments, walkers, and traffic lights. The capacity of CNNs to perceive protests and decipher the general climate progressively makes them an irreplaceable part of present day self-driving vehicles.

4. IoT Frameworks

In IoT-based frameworks, CNNs are utilized to process immense measures of unstructured information, like pictures

from surveillance cameras, sound information from sensors, or natural information from brilliant gadgets. One region where CNNs are especially helpful is in brilliant observation frameworks, where they can recognize strange examples or occasions, for example, unapproved access or gear glitches, by dissecting video takes care of continuously. CNNs can likewise be joined with edge figuring to empower on-gadget deduction, where handling is finished on neighborhood gadgets as opposed to in the cloud, guaranteeing quicker and more effective decision-production in IoT conditions.

5. Healthcare and Clinical Imaging

CNNs have shown critical commitment in the field of medical services, especially in clinical imaging. They are utilized to investigate X-beams, X-ray checks, and different sorts of clinical pictures to distinguish irregularities like cancers, breaks, or different infections. CNNs are equipped for figuring out how to perceive unobtrusive examples in clinical pictures, frequently awe-inspiring human-level execution in errands like identifying harmful cells in histopathology slides.

2.1.2.4 CNNs in Protection Safeguarding IoT Frameworks

In IoT-based frameworks, protection is a main pressing issue, particularly when touchy information like pictures, sound, or individual data is communicated among gadgets and the cloud. CNNs can be sent in protection safeguarding IoT structures in different ways:

1. Federated Learning: CNNs can be integrated into united learning structures, where models are prepared locally on gadgets without sharing crude information. All things considered, gadgets just offer updates to the model boundaries with a focal server. This guarantees that delicate information stays on the gadget while as yet profiting from a worldwide, shared model.

2. Homomorphic Encryption: CNNs can likewise be joined with cryptographic methods like homomorphic encryption, permitting the model to perform procedure on scrambled information while never unscrambling it. This is especially valuable for medical services and observation frameworks, where classification is basic.

3. Edge Figuring: CNNs are progressively being conveyed tense gadgets, like cameras or IoT entryways, where the information is handled locally as opposed to being shipped off the cloud. This diminishes dormancy and transmission capacity use as well as upgrades security by keeping the information inside the neighborhood organization.

2.1.2.2 Challenges and Limitations of CNNs

1. **Computational Complexity**: CNNs require significant computational assets because of the enormous number of boundaries and tasks included, particularly as the organization profundity increments. This can make preparing and conveying CNNs on asset obliged gadgets like IoT sensors testing.
2. 2. Overfitting: As CNNs can learn multifaceted examples in the preparation information, they are inclined to overfitting, particularly while the preparation dataset is little. Procedures like information increase, dropout, and early halting are utilized to relieve this issue, however the gamble remains.
3. 3. Interpretability: Despite the fact that CNNs have been profoundly fruitful in assignments like picture acknowledgment, they are frequently thought of "black-box" models because of their complex inward construction. It very well may be challenging to decipher precisely the way that a CNN shows up at a particular choice or which highlights it considers significant. Convolutional Brain Organizations have altered many fields, especially PC vision, and are progressively being applied to IoT-based frameworks for assignments like ongoing observing, peculiarity discovery, and security safeguarding. Their capacity to catch spatial orders and interaction high-layered information makes them appropriate for different applications, going from clinical imaging to independent vehicles. Notwithstanding their difficulties, CNNs keep on advancing, with developments, for example, unified learning and edge processing improving their organization in certifiable IoT conditions.
4. 2.1.3 Support Vector Machine (SVM) Classifier
5. Support Vector Machines (SVMs) are a strong class of directed learning calculations utilized for characterization, relapse, and exception identification undertakings. Initially created by Vladimir Vapnik and his associates during the 1990s, SVMs have become one of the most broadly utilized AI calculations because of their flexibility and adequacy in high-layered spaces. They are especially appropriate for parallel arrangement issues yet can be reached out to multi-class order too. The center thought behind SVMs is to find a hyperplane that best isolates the data of interest of various classes while boosting the edge between the two classes.
6. 2.1.3.1 The Center Ideas of SVMs

7. 1. Hyperplane and Choice Limit

8. A SVM classifier works by distinguishing a choice limit (or hyperplane) that isolates data of interest into particular classes. In a 2D space, this hyperplane is just a line that partitions the information, while in higher aspects, the hyperplane turns out to be more mind boggling. The objective of the SVM is to find the ideal hyperplane

9.

10. that isolates the useful pieces of information as well as augments the edge, which is the distance between the hyperplane and the closest data of interest from each class. These closest focuses are called help vectors since they are the basic components that characterize the choice limit.

11. Numerically, given a dataset with nnn tests and each example addressed as a component vector xi∈Rdx_i \in \mathbb{R}^dxi∈Rd, the goal of SVM is to find a hyperplane characterized by wTx+b=0w^T x + b = 0wTx+b=0, where www is the weight vector and bbb is the predisposition term. The ideal hyperplane is the one that boosts the edge between the two classes, with the edge being the distance between the help vectors and the hyperplane.

12. 2. Maximum Edge Classifier

13. The idea of amplifying the edge is central to SVMs. The edge is the opposite separation from the choice limit to the nearest pieces of information from one or the other class. By boosting this edge, the SVM plans to make a more summed up classifier that is less inclined to overfit the preparation information. This approach is known as the most extreme edge standard.

14. The streamlining issue in SVM can be figured out as:

15.

16. This definition guarantees that the information focuses are accurately ordered and that the edge is amplified.

17. 3. Support Vectors

18. The help vectors are the information focuses that lie nearest to the hyperplane and are essential in characterizing the choice limit. These focuses are the most challenging to characterize accurately, and the hyperplane is built in view of them. Assuming any help vector were taken out, the place of the hyperplane would change, showing their significance in SVMs.

19. 4. Linear versus Non-direct SVMs

20. SVMs can deal with both directly distinguishable and non-straightly divisible information:

21. • Straight SVM: In situations where the information is directly detachable, the SVM calculation can straightforwardly find the ideal hyperplane that isolates the two classes with a most extreme edge.

22. • Non-direct SVM: In some true situations, information isn't straightly detachable, implying that no straight line or hyperplane can totally different the classes. To address this, SVMs utilize a strategy known as the bit stunt to plan the first information into a higher-layered space

23.

24. where a direct hyperplane can isolate the classes. By utilizing various kinds of bits, SVMs can really deal with complex, non-straight characterization issues.

25. 2.1.3.2 Kernel Capabilities

26. The bit stunt is a strong numerical procedure that permits SVMs to work in a higher-layered space without expressly figuring the directions of the information there. All things considered, the part capability registers the inward item between two focuses in the changed space. The most normally utilized parts include:

27. 1. Linear Part: The easiest piece is the straight portion, which is utilized when the information is directly divisible. The direct bit processes the spot item between two vectors: K(xi,xj)=xiTxj

28. 2. Polynomial Part: This bit maps the information highlights into a higher-layered space utilizing polynomial mixes of the information factors. The polynomial bit capability is addressed as K(xi,xj)=(xiTxj+c)d, where ccc is a steady and ddd is the level of the polynomial.

29. 3. Radial Premise Capability (RBF) Piece: The RBF portion, otherwise called the Gaussian bit, is broadly utilized in SVMs because of its capacity to deal with non-straight information. It maps the info space into a limitless layered space and is characterized as K(xi,xj)=exp(−γ|| xi−xj|| 2), where γ\gammaγ is a free boundary that controls the spread of the portion.

30. 4. Sigmoid Bit: The sigmoid piece depends on the sigmoid capability and is ordinarily utilized in brain organizations. It is characterized as K(xi,xj)=tanh(αxiTxj+c) = \tanh(\alpha x_i^T x_j + c)K(xi,xj), where α\alphaα and ccc are portion boundaries. The decision of portion relies upon the idea of the information. For example, the RBF part is normally utilized when the information isn't

straightly divisible and displays complex connections, while the direct piece is more reasonable for easier, straightly detachable datasets.

31. 2.1.3.3 Soft Edge SVM and C Boundary

32. By and by, amazing direct distinctness is uncommon, and there might be occasions of misclassification, particularly with uproarious information. Delicate edge SVM permits a few information focuses to be misclassified to further develop speculation. This is accomplished by presenting a leeway variable ξi\xi_iξi and a regularization boundary CCC, which controls the compromise between expanding the edge and limiting the grouping mistake. The advancement issue for the delicate edge SVM becomes:

$$\min \frac{1}{2}||w||^2 + C\sum_{i=1}^{n}\xi_i$$

subject to $y_i(w^T x_i + b) \geq 1 - \xi_i$, where $\xi_i \geq 0$.

The boundary C goes about as a regularization term. A more modest C permits a bigger edge however may bring about more misclassified focuses, while a bigger C powers the SVM to accurately order more focuses, possibly at the gamble of overfitting.

2.1.2.3 Applications of SVM

1. Text Order and Normal Language Handling (NLP)

SVMs have been broadly utilized in message grouping undertakings, like spam discovery, opinion examination, and report order. The high-layered nature of message information (addressed as word vectors) makes SVMs especially successful, particularly while utilizing pieces like the RBF or direct portion. SVMs' capacity to deal with scanty and high-layered datasets makes them ideal for undertakings, for example, email separating or subject characterization.

2. Image Arrangement

SVMs have been applied in picture arrangement undertakings, where they have major areas of strength for exhibited. When joined with include extraction procedures like Histogram of Arranged Slopes (Hoard) or Scale-Invariant Element Change (Filter), SVMs can group pictures in light of visual highlights. While convolutional brain organizations (CNNs) overwhelm picture acknowledgment today, SVMs stay a famous decision in situations where less difficult models are liked or when computational assets are restricted.

3. Anomaly Location

SVMs are likewise broadly utilized for inconsistency location, where the assignment is to recognize intriguing occasions or exceptions. Via preparing on ordinary information, a SVM can gain proficiency with the limit of run of the mill conduct and banner any information focuses that fall outside this limit as irregularities. This is particularly valuable in applications like extortion identification, network interruption recognition, and gear disappointment forecast in IoT frameworks.

4. IoT Frameworks

In IoT-based frameworks, SVMs are applied for ongoing navigation, particularly in security-related assignments like interruption location and sensor-based abnormality discovery. Because of their vigor and

capacity to deal with high-layered information, SVMs are appropriate for asset obliged IoT conditions. They can be

conveyed anxious gadgets to arrange information streams or identify irregularities without depending vigorously on cloud-based calculation.

2.1.2.4 Strengths of SVMs

1. Effective in High-Layered Spaces: SVMs are especially appropriate for issues with high-layered information, like text and picture characterization. Their capacity to work in these spaces without experiencing the scourge of dimensionality settles on them a well known decision for complex issues.
2. Robust to Overfitting: SVMs are intrinsically intended to forestall overfitting by expanding the edge between classes. The regularization boundary CCC takes into account further command over the compromise between model intricacy and grouping exactness.
3. Versatile Piece Capabilities: SVMs can be adjusted to a large number of information types and circulations using part works. This flexibility makes SVMs pertinent in different areas, from PC vision to bioinformatics.
4. Effective in Little Datasets: Not at all like some AI calculations that require a lot of information to perform well, SVMs are viable in any event, when the size of the dataset is generally little.

2.1.2.5 Limitations of SVMs

1. Computational Intricacy: SVMs can be computationally costly, particularly for enormous datasets. Preparing a SVM requires tackling a quadratic improvement issue, which can become restrictive as the quantity of tests increments. This makes SVMs less appropriate for enormous scope applications contrasted with calculations like choice trees or brain organizations.
2. Choice of Portion and Boundaries: The exhibition of SVMs vigorously relies upon the decision of piece and hyperparameters, for example, CCC and γ\gammaγ. Choosing some unacceptable bit or hyperparameters can prompt lackluster showing, and enhancing these boundaries can time-consume.
3. Interpretability: Despite the fact that SVMs give a hearty order component, they are frequently thought of "black-box" models. It very well may be trying to decipher the subsequent model, particularly when non-direct portions are utilized. Support Vector Machines (SVMs) stay perhaps of the best and flexible classifier in the AI tool kit. Their capacity to function admirably with high-layered information, joined with the adaptability of piece capabilities, permits them to handle a wide assortment of issues, from text characterization and picture acknowledgment to oddity recognition in

IoT frameworks. In spite of difficulties, for example, computational intricacy and boundary tuning, SVMs keep on being a significant device in spaces where exactness and speculation are of fundamental significance.

2.2 Review of Related works

Currently settled deal with on the problems of current ML strategies for IoT security is talked about in this segment. A portion of these reviews order and study research on ML strategies and IoT security exclusively, which are featured in the initial segment of this part. At long last, the overview of studies is led with an outline and survey of reviews on AI based security draws near.

In Butun et al. (2018) IoT assaults are assembled into inactive and dynamic assaults. The OSI-layer model is utilized to additionally recognize dynamic assaults. The assembled protection components against assaults towards remote sensor organizations (WSNs) and IoT cover numerous aspects. These incorporate cryptography, encryption calculations, AI techniques (for example swarm knowledge), equipment and systems administration conventions, among others. This study centers around IoT security more intensely than the accompanying five reviews. There exist different writing overviews on the utilization of AI techniques for IoT Security (Bonawitz et al., 2019). In the accompanying segment some of these overviews are summed up and audited.

Machine Learning in IoT Security: Current Arrangements and Future Difficulties Hussain et al., (2018) have composed a study that classifies the security dangers into layers, like the OSI-layers with the expansion of multifaceted and cloud-based assaults. These security and protection issues found in IoT are then additionally portrayed as far as the security prerequisites and assault surfaces of IoT gadgets. The ongoing utilization of AI for IoT security is depicted and gathered by ML calculation type. Besides, the constraints of customary ML procedures and the average impediments of utilizing ML approaches in IoT conditions are examined, including handling power, energy, information the board and information examination. The study go on with a portrayal of the current ML-based answers for a few IoT security issues comparing to verification, location and examination. DoS and Conveyed DoS assaults are analyzed independently from the general assault and irregularity/interruption discovery techniques. At last, the open issues and future exploration headings are distinguished, which incorporate the limits of DL, DRL, IoT Information and effectiveness. The study by Hussain et al. gives a very much organized and obvious outline over the crossing point of IoT security and ML arrangements. Having the scientific classification of the review gives a reasonable blueprint for perusers to recognize explicit assaults or ML answers for

read about. Besides, giving the illustrations

learned gives a decent rundown of the critical important points from the past segment. Contrasted with other overviews concentrated on in this part, access control strategies and confirmation are examined by Hussain et al. indeed. Their overview of examination papers on ML and DL-based admittance control and confirmation techniques gives assortment when most strategies considered are recognition based.

A weakness is that main a restricted measure of safety gives that are tended to by ML strategies are incorporated, either because of absence of examination in those areas or non-pertinence and degree. By and large, the review is a decent preview of the momentum research on ML strategies for IoT security and gives a definite course to additional examination commitment contains the singular depiction of the cutting edge in IoT framework assault vectors and the utilization of ML and DL techniques to battle these assault weaknesses. Furthermore, the overall IoT framework qualities and layers are depicted, giving a bases to why gambles for IoT security are available. Following these framework attributes the security properties are given whereupon various strategies can measure up. The dangers referenced in the paper are ordered into physical, network, cloud, web and application, and new assault surfaces. A broad survey of a larger part of AI and profound learning techniques is led. The benefits and burdens of every technique are given and the appropriateness to IoT security is referenced. Most techniques can be utilized for differing types of location. The examinations on the best in class techniques are summed up and looked at. At long last, in the wake of social affair the foundation and cutting edge research, the issues, difficulties and future exploration headings are proposed. These incorporate the improvement of safety related datasets, the requirement for ML and DL techniques to keep up with high precision on low-loyalty information, the expansion of IoT security information, the decision of various learning procedures in view of the sort and time period of the assault, and the utilization of ML and DL in various conditions. Finally ML and DL issues, DL/ML incorporation draws near (for example blockchain) and security compromises are introduced.

The study by Al-Garadi et al. gives a very much organized and complete scientific classification of the utilization of AI and Profound Learning for IoT security. Their diagram of the scientific classification gives a visual outline of the study and guides the peruser along the ideas and construction. As far as broadness of conversation on ML and DL strategies, this review gives a more extensive territory contrasted with the other overviews considered. One more benefit of the overview is the broad rundown of safety properties and their aggressive messages, for which the connected work is featured. Then again, a portion

of these properties (for example non-renouncement) are not additionally used to assess and think about the ML strategies and ML-coordinated approaches. The incorporation of ML and DL security related issues and future examination bearings is a useful quality

of the paper, because of the restricted measure of exploration on protection safeguarding strategies by the other overviews. A marginally unique naming show to the OSI model is utilized and cloud administrations is incorporated. Their order is more granular however the design is unique in relation to what most of the concentrated on overviews have. At last one more weakness is the restricted conversation on approval and ML/DL answers for access control security. Most of approaches base on identification, where an absence of relief strategies is obvious.

Machine Learning-enabled IoT Security: Open Issues and Difficulties Under Cutting edge Persevering Dangers by Chen et al. overview the writing on AI empowered IoT security with a unique spotlight on Cutting edge Constant Dangers (Able) in IoT Security. The protection against cutting edge determined dangers is significant yet testing considering their long-lasting casing and secret nature. The study opens with security elements of IoT and modern IoT, examining the different IoT layers. Then, at that point, the ordinary assaults, Well-suited assaults and danger model investigation on IoT are made sense of. As far as interruption recognition, signature-based, oddity based, and crossover approaches are examined and arranged. Three gatherings of AI calculations are assessed: regulated, solo and profound learning calculations. Factual outcomes and datasets are introduced close by the calculation assessments. At long last, the fundamental commitments are the arrangement of open issues, difficulties and open doors. These are given for network interruption as well as Able assault identification. The issues for network interruption are refreshed assault location, IoT information qualities (for example heterogeneity), and ML calculation choice and arrangement. For Able assault recognition the absence of a devoted dataset, AML-based identification and the blend with malware discovery are proposed future exploration bearings. The benefit of the review by Chen et al. is that the generally low measure of examination into Able identification is a decent premise to construct further exploration in this subject. High level industrious dangers can be exceptionally harming when stowed away contrasted with different assaults that don't go on over a more drawn out timeframe (Smith et al., 2021). Furthermore, the low measure of investigation into Able contrasted with other assault vectors like DoS discovery, is one more justification for why the overview by Chen et al., is useful. Contrasted with the other studies the ML-based arrangements are classified into the Well-suited structure. Well-suited's are as yet wide as far as the particular assaults and

strategies that are utilized inside it, since it has six phases. Different moderation, discovery and aversion amazing open doors exist in these stages (for example observation, introductory split the difference, later development, resource revelation, information ex-filtration) (Abadi et al., 2020). One more benefit of the review is the assessment of IoT informational collections. The datasets are recorded and assessed, which helps analysts that utilization the study by Chen et al. for their own examination. At long last,

having been distributed in 2022 the recency of the overview is profitable. The weakness of the review is the predetermined number of papers assessed that completely envelop a Well-suited recognition, relief and evasion approach. Most papers center around interruption discovery, while investigation into evasion and relief is examined less significantly. AI Progressively Web of Things (IoT) Frameworks: A Review (Lopez and Trumer, 2021) An overview by Bian et al. examines the present status of-the-craftsmanship in tending to the difficulties of involving ML continuously frameworks. Constant frameworks that consider the timing part are significant for basic foundation applications, as referenced by the paper.

The design for their examination on ML continuously IoT frameworks is separated into three areas. The planning investigation is significant for giving an assurance of convenient execution. Adjusting profound brain organizations to continuous frameworks requires model pressure and pipeline streamlining. Finally protection and security related difficulties in the conglomeration and it are examined to cycle of delicate data. A gathering of ML/DL-based answers for various applications (for example ventures) and their concerns follows. The future exploration bearings for ML for RTS are using a more probabilistic methodology towards consistency, vindictive conduct discovery and continuous framework recuperation, which handles relief. Finally the induction and preparing time restrictions of RTS ought to be dealt with and an assurance on gathering time requirements ought to be explored further. Bian et al. furnish a study with various benefits and impediments. A benefit integral to the study is the high significance of investigation into ongoing frameworks and their security. The utilization of RTS in basic foundation in the enterprises of transportation, modern conditions, medical services and brilliant urban areas requires further examination into how AI can be actually utilized in these conditions. Productivity of ML strategies is significant in these frameworks. Having a review on the best in class in scheduleability and time imperative ML gives an alternate point of view for scientists in expansion to the exactness of danger identification strategies. One more benefit is the immediate association with industry applications. The study gives a reasonable outline of the various ventures that have RTS, their concerns, a depiction of gadgets and the arrangements utilizing customary and ML/DL-based strategies. This part gives an

association between the examination and industry and helps scientists in finding contextual investigations to coordinate their exploration towards. One issue of the review by Bian et al. is the restricted measure of spotlight on security and protection. Issues as far as protection and security information handling and examination are talked about somewhat, yet not as extensively as other overviews.

How AI Changes the Idea of Cyberattacks on IoT Organizations: An Overview (Dwork et al., 2020) From the hostile course Session et al. overview the cutting edge in ML-based assaults.

Portrayed are brilliant assaults that are less effectively discernible, more designated, self-arranging and can dissect and produce information to use for infusion. To do so Session et al. audit overviews on broad IoT assaults, ML use in IoT organizations and ML-based answers for IoT security issues. An outline of savvy ML-based assaults partitioned into four classes is given and countermeasures and open issues are introduced. At long last, the expanded intricacy, heartiness and flexibility of ML-based assaults guide further investigation into these techniques. The ongoing difficulties introduced are learning streamlining, improved datasets, refreshed assessment strategies, using antagonistic assaults for security strength and guard testing.

The benefits of the review by Session et al., (2018) is that it focuses on the area of IoT security according to an alternate point of view that the other overviews considered. An expanded comprehension of savvy ML-based assaults can help scientists in finding answers for these and working on the security and effectiveness of IoT organizations. Another benefit is the expanded examination and development of ML-based assaults, which features the significance. As a primary drawback the future exploration headings are not quite so broad as other reviews. An expanded measure of investigation into shrewd assaults without greater examination into, for instance the strength of AI techniques against ill-disposed assaults, could diminish the security and productivity of IoT networks generally.

2.1.3 Secure Total Methods for IoT based exercises

The boundless reception of IoT gadgets for action acknowledgment has prompted a deluge of individual information being gathered, handled, and dissected. This has raised huge protection concerns, requiring the improvement of powerful security saving strategies. Differential Protection, a structure intended to guarantee that the expansion or evacuation of a solitary information point doesn't fundamentally influence the result of the investigation, has built up momentum as an answer (Dwork et al., 2020).

Differential Security accomplishes protection conservation by adding commotion to collected information, making it hard to recognize individual commitments while as yet getting significant

experiences. This approach is especially pertinent in IoT-based action acknowledgment situations, where it is fundamental to keep up with client security. Secure collection strategies assume a crucial part in executing Differential Protection in IoT settings. Methods like Combined Learning, Homomorphic Encryption, and Multi-Party Calculation empower the accumulation of information across conveyed gadgets without uncovering individual data of interest.

The coordination of secure total strategies with Differential Protection upgrades protection safeguarding by limiting the gamble of information spillage and safeguarding individual characters. It considers

exact action acknowledgment while limiting the gamble of re-distinguishing proof assaults. A few contextual investigations and true applications exhibit the commonsense execution of secure collection methods for protection safeguarding IoT-based action acknowledgment. These models feature the achievability and viability of the proposed approach. Notwithstanding the headway made, difficulties, for example, enhancing commotion boundaries, adjusting security and utility, and dealing with antagonistic assaults remain. Future exploration ought to zero in on refining existing strategies, creating normalized systems, and addressing these difficulties to guarantee far and wide reception.

Secure collection methods, related to Differential Protection, offer a promising road for upgrading protection safeguarding AI in IoT-based action acknowledgment. These procedures successfully safeguard individual protection while empowering exact information examination, making ready for a safer and security cognizant IoT environment. By coordinating secure conglomeration procedures with Differential Protection, IoT-based movement acknowledgment can accomplish an ideal harmony between information utility and individual protection. As innovation keeps on developing, refining and propelling these strategies will be vital in guaranteeing the protection and security of clients in the always growing IoT scene.

2.1.3 Case examinations and Applications Combined Learning for Wellbeing Checking:

In a review directed by Sheller et al. (2020), united learning was utilized for security safeguarding action acknowledgment in wellbeing observing utilizing wearable gadgets. The methodology included preparing AI models cooperatively across disseminated gadgets while keeping crude information restricted. Secure conglomeration methods empowered the focal model to be refreshed without unifying delicate information, guaranteeing individual protection and working on the exactness of wellbeing movement acknowledgment. (Sheller et al., 2020).

Savvy Home Security with Homomorphic Encryption:

A certifiable application created by Lee et al. (2018) used homomorphic encryption to guarantee protection in shrewd home security frameworks. The framework permitted brilliant cameras to identify and perceive exercises without

uncovering the crude information. Homomorphic encryption strategies were utilized to perform calculations on encoded information, and secure conglomeration empowered examination without uncovering individual exercises, making it appropriate for IoT-based action acknowledgment in delicate conditions. (Lee et al., 2018).

Cooperative Oddity Discovery for Modern IoT:

In a modern setting, joint effort among IoT gadgets is critical for oddity recognition and upkeep. Tune et al. (2019) introduced a contextual analysis where Multi-Party Calculation (MPC) was utilized for secure conglomeration of tangible information from various gadgets for irregularity recognition in modern cycles. By applying MPC, individual gadgets shared scrambled data without uncovering crude information, guaranteeing the protection of every gadget's commitment while aggregately distinguishing irregularities. (Tune et al., 2019).

Security Saving Group Observing in Brilliant Urban communities:

Metropolitan conditions frequently demand ongoing group checking for security and the executives. A certifiable application by Jiang et al. (2017) exhibited the utilization of secure accumulation methods for protection safeguarding swarm observing. By utilizing combined learning, encoded information from different IoT gadgets, like reconnaissance cameras and sensors, was totaled without compromising individual security. The amassed model gave experiences into swarm elements while forestalling the openness of individual data. (Jiang et al., 2017).

Action Acknowledgment in Wearable Wellness Gadgets:

Wearable wellness gadgets frequently track clients' exercises for wellbeing and wellness checking. To address security concerns, Lu et al. (2020) proposed a protected collection strategy for conglomerating action information from numerous wearable gadgets. Homomorphic encryption was utilized to empower the conglomeration of encoded action information while keeping up with individual protection. The methodology took into account precise action acknowledgment without uncovering explicit client data. (Lu et al., 2020).

These contextual analyses and certifiable applications feature the useful execution of secure accumulation methods in different IoT-based situations for action acknowledgment. By coordinating these methods with security saving instruments, for example, Differential Protection, these arrangements offer a harmony between exact examination and individual protection insurance.

2.1.4 Comparison between Combined Learning and Secure Total Procedures

Combined Learning and Secure Accumulation Procedures are both protection saving methodologies that expect to empower cooperative AI across appropriated gadgets while safeguarding delicate information. Be that as it may, they contrast in their procedures and applications. We should dive into an examination of these two procedures:

System:

Combined Learning includes preparing AI models cooperatively across numerous gadgets while keeping crude information confined. Models are refreshed iteratively by conglomerating nearby model updates from

partaking gadgets, typically under the management of a focal server while Secure Conglomeration Methods, then again, center around the total of encoded information from disseminated gadgets. These strategies guarantee that crude information remains encoded during total, keeping up with individual security. Strategies, for example, Homomorphic Encryption and Multi-Party Calculation empower calculations on encoded information without uncovering touchy data (Dwork et al., 2020).

Information Protection:

Combined Advancing basically centers around security safeguarding by keeping crude information decentralized. It doesn't be guaranteed to guarantee that the crude information itself remains scrambled during the model update process while Secure Accumulation Strategies succeed in safeguarding information protection by guaranteeing that delicate information remains encoded all through the collection cycle. This limits the gamble of information spillage, in any event, during calculation.

Correspondence Above:

United Learning includes correspondence among gadgets and the focal server during model updates. Correspondence above can be a worry, especially while managing an enormous number of gadgets while Secure Collection Strategies frequently include more complicated cryptographic tasks, prompting possibly higher correspondence above. Nonetheless, progressions in cryptography have been alleviating this worry after some time.

Pertinence:

Combined Learning is appropriate for situations where information stays conveyed across gadgets, like cell phones, edge hubs, and IoT gadgets (Dwork et al., 2020). It is especially helpful when the crude information itself isn't effectively shareable because of protection or administrative reasons while Secure Collection Strategies track down applications in situations where information protection is of principal significance. This incorporates situations where crude information sharing is totally disallowed, as in delicate medical care information or classified modern cycles.

Information Utility and Exactness:

Unified Gaining can now and again experience the ill effects of information heterogeneity across gadgets, prompting difficulties in accomplishing high exactness. Amassing models from assorted sources could expect procedures to relieve this issue while Secure Conglomeration Strategies mean to keep up with information utility and exactness while protecting security by performing calculations on scrambled information. Be that as it may, clamor presented

during encryption can influence the last precision somewhat.

2.2 Summary/meta-analysis of Reviewed of Related Works

Analysts have featured the security challenges related with IoT-based action acknowledgment frameworks, underscoring the dangers of individual information assortment and handling. To address these difficulties, the idea of differential protection has arisen as a promising arrangement. Differential security gives a numerical system to evaluate and restrict the protection misfortune coming about because of information incorporation or rejection. United learning has acquired critical consideration as a protection safeguarding method for IoT-based movement acknowledgment. It permits cooperative preparation of AI models on disseminated IoT gadgets without moving crude information to a focal server. All things being equal, neighborhood model updates are performed on every gadget, and just totaled model updates are traded. This approach guarantees that singular information protection is kept up with.

Secure collection strategies assume a crucial part in combined advancing by empowering the protected total of neighborhood model updates. Cryptographic conventions, secure multi-party calculation, and different instruments are utilized to total updates while saving the classification of delicate data. These procedures keep foes from separating private information from the collected updates.

Analysts have created security safeguarding AI calculations explicitly custom fitted for movement acknowledgment in IoT conditions. These calculations consolidate differential protection, unified learning, and secure collection to guarantee security ensures without forfeiting utility. They plan to work out some kind of harmony among security and precision while considering the computational and correspondence imperatives of IoT gadgets (Goldwasser et al., 2019).

The compromises among security and utility in differential protection and unified learning have been broadly examined. Specialists have investigated the effect of security safeguarding methods on the precision, computational proficiency, and correspondence above of movement acknowledgment models (Froelicher et al., 2020). It has been seen that while security measures acquaint commotion or irritation with protect protection, they may marginally corrupt the utility of the models. Tracking down the right harmony among security and utility remaining parts a test.

Assessment measurements have been proposed to evaluate the viability and protection certifications of security saving AI methods. Measurements like security misfortune, precision, vigor, and reasonableness have been utilized to assess the exhibition of these methods in IoT-based movement acknowledgment situations.

Genuine applications and contextual analyses have shown the reasonable execution and assessment of security

safeguarding AI for IoT-based movement acknowledgment. These examinations have featured the qualities, limits, and potential for more extensive reception of the proposed strategies.

Be that as it may, a few open difficulties and future headings have been distinguished. Working on the productivity of security safeguarding procedures, tending to the heterogeneity of IoT conditions, and guaranteeing protection in complex movement acknowledgment situations are regions that require further examination and headways. The checked on related work gives important experiences into improving security saving AI for IoT-based movement acknowledgment. It features the meaning of differential protection, unified learning, and secure collection strategies in keeping up with individual protection while accomplishing exact and helpful forecasts. The exploration reveals insight into the compromises, assessment measurements, true applications, and future bearings in this developing field.

CHAPTER THREE
RESEARCH METHODOLOGY

3.1 Preamble

The motivation behind this section is to give satisfactory and proper techniques to this review. Notwithstanding, the fundamental goal of the techniques utilized in this study endeavors to address the examination questions expressed and speculations hypothesized. This part covered issue plan, proposed arrangement, apparatuses and so on.

3.2 Problem plan

This intends to distinguish the critical difficulties and issues tended to by the review in light of the survey of related works recently finished and give an unmistakable course to the exploration technique.

The procedure embraced gives an organized way to deal with upgrading security in IOT frameworks utilizing CNN, SVM, and RF AI methods. Via cautiously following these means, a powerful and dependable model will be made to upgrade the security of IoT conditions. This includes the utilization of numerical calculations and strategies to foster a model that can gain from information and make forecasts or characterizations on new datasets. This interaction regularly includes the accompanying advances:

1. Dataset Procurement: Datasets pertinent to IoT network traffic is obtained from Kaggle information archive. In particular, shrewd home IoT information.

2. Data Preprocessing: Clean and preprocess the information to deal with missing qualities, standardize includes, and encode clear cut factors.

3. Feature extraction: When the information has been arranged, the subsequent stage is to separate applicable highlights. Recognizing and extricate applicable highlights that add to interruption recognition, for example, Parcel size, Source and objective IP addresses, Convention type (TCP, UDP, and so on), Time stretches between bundles.

4. Model Determination: Pick the AI calculations to carry out:

i. Convolutional Brain Organizations (CNN): Appropriate for design acknowledgment in complex datasets.

ii. Random Woods (RF): A strong troupe learning strategy that handles imbalanced datasets well.

iii. Support Vector Machines (SVM): Viable for order undertakings with a reasonable edge of partition.

5. Model Preparation and Approval: this methodology incorporates Information Parting that partition the dataset into preparing, approval, and test sets (e.g., 70% preparation, 15% approval, 15% testing),

o Model Preparing: Train each model utilizing the preparation dataset. For CNNs, plan the design (number of layers, channel sizes, actuation works) and assemble the model. For SVM and RF, improve hyperparameters (e.g., part types for SVM, number of trees for RF) utilizing lattice search or irregular inquiry. Utilize k-overlap cross-approval to guarantee model strength and forestall overfitting.

6. Model Assessment: Assess model execution utilizing proper measurements, for example, Exactness, Accuracy, Review, F1-score, Recipient Working Trademark (ROC) bend and Region under the Bend (AUC). Look at the presentation of the CNN, SVM, and RF models to decide the best methodology.

3.3 Proposed Arrangement, Procedure, Model or Structure

This approach expects to examine, carry out, and assess various methods to address the exploration issue and accomplish the examination targets.

Choice of Protection Saving AI Procedures:

The initial step is to choose proper protection safeguarding procedures for the review, which ought to settle the difficulties talked about in the past related models; differential protection, united learning, and secure conglomeration. Irregular Woods and Convolutional Brain Organizations (for expectation) with Help Vector Model (for characterization) will be utilized in this review. The method is picked in view of its significance to IoT-based action acknowledgment and its capacity to protect security while keeping up with utility.

Dataset Assortment and Preprocessing:

IoT-based action acknowledgment datasets will be gathered from Kaggle which contain sensor information from different IoT gadgets. The gathered information will go through preprocessing to eliminate commotion, anomalies, and insignificant elements. Security saving procedures, for example, information anonymization and encryption, will be applied to safeguard individual protection.

Execution and Assessment AI:

AI components will be carried out to infuse clamor or annoyance into the information. Different techniques,

for example, arbitrary commotion expansion or nearby differential protection, will be investigated. The effect of AI on security misfortune, precision, and utility will be assessed utilizing suitable assessment measurements.

Similar Examination and Execution Assessment:

A similar examination will be directed to look at the viability and execution of specialist's model over differential protection, combined learning, and secure collection methods. Assessment measurements, for example, Exactness, Accuracy and Review will be utilized to evaluate the compromises among protection and utility. The examination will give experiences into the qualities and limits of every procedure.

3.3.1 System Models

Man-made brainpower models were proposed and utilized in this exploration work.

a. The model is given below with consideration of CNN (Neural Network).

$$y = f(X, W) + e_i \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots i$$

$$y = f(X, W) + e_i = aX = \sum_{h=0}^{h} \beta h g \left(\sum_{i=0}^{i} r_{hi} X_i \right) + e_i \quad \ldots\ldots\ldots\ldots ii$$

$$y = f(X, W) + e_i \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots iii$$

$$aX = \sum_{h=0}^{h} \beta_h (1 + e^{-x})^{-1} \left(\sum_{i=0}^{i} r_{hi} X_i \right) + e_i \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots iv$$

$$g(.) = \frac{1}{1 + e^{-1}} = (1 + e^{-x})^{-1} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots v$$

$$where X = (e_0 = 0, x_{1,\ldots\ldots x_i}); w = (\propto, \beta, \gamma); \ldots\ldots\ldots\ldots\ldots\ldots vi$$

Where,

Y Is the output variable (Target, grade)

X Is the input variables (independent, score)

α Is the weight of the input unit(s)

β Is the weight of the hidden unit(s)

γ Is the weight of the output unit(s),

g(.) is the logistic transfer function;

e_i is the error term.

b. Support Vector Machines (SVM) mathematical Model

$$\min_{\mathbf{w},b} \frac{1}{2}\|\mathbf{w}\|^2$$

subject to the constraints:

$$y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1 \quad \forall i$$

Where:

- $\mathbf{w}$ is the weight vector.
- b is the bias.
- y_i is the label of instance i.
- $\mathbf{x}_i$ is the feature vector of instance i.

A. Random Forests (RF)

1. **Decision Tree Model:** Each tree T is represented as a series of decisions:

$$T(\mathbf{x}) = \text{argmax}_j \sum_{i \in I} \mathbb{I}(h(\mathbf{x}) = j)$$

where:

- h is the decision function.
- I is the index set of samples reaching the leaf node for input $\mathbf{x}$.
- $\mathbb{I}$ is the indicator function.

2. **Ensemble Prediction:** The final prediction from a Random Forest with N trees is given by:

$$\hat{y} = \frac{1}{N} \sum_{n=1}^{N} T_n(\mathbf{x})$$

for regression, or by majority voting for classification:

$$\hat{y} = \text{mode}(T_n(\mathbf{x}))$$

3.1.1 Network Architecture and Design

A. Network architecture for Convolutional Neural Network (CNN).

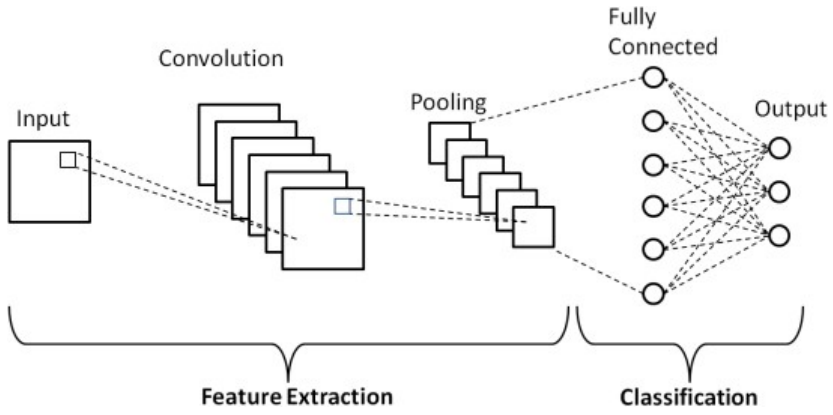

Fig 3.1 CNN (Adopted from https://www.aibutsimple.com/p/modern-convolutional-neural-network-architectures)

B. Network architecture for Random Forest

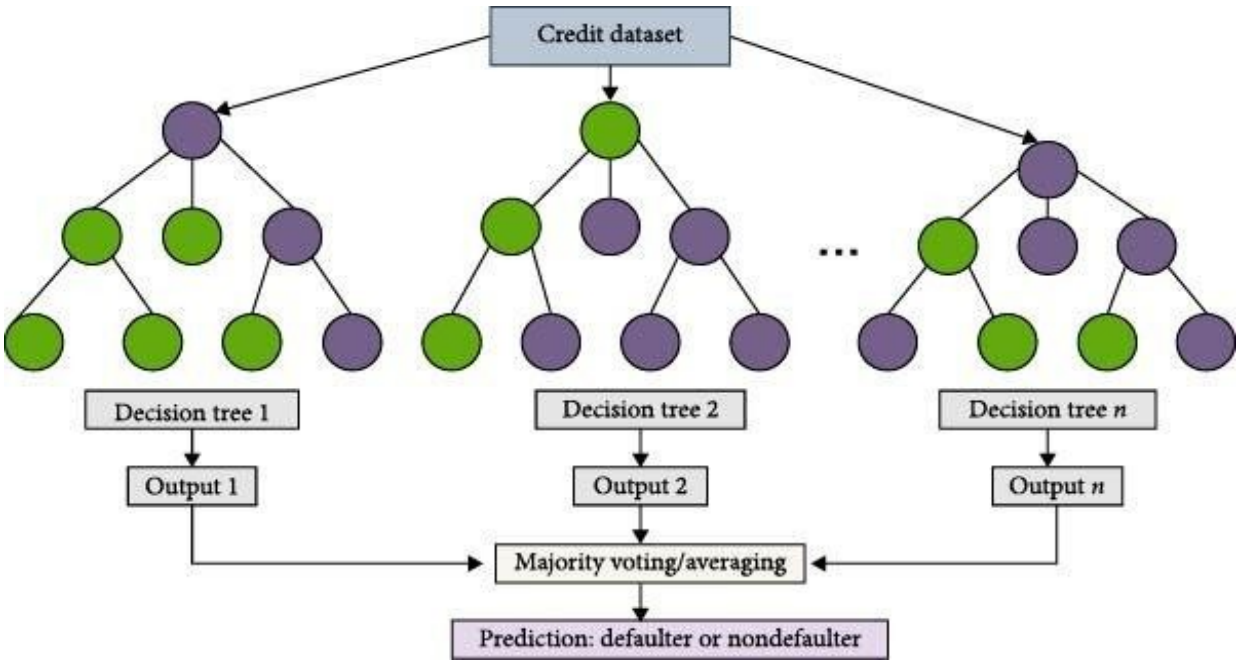

Fig 3.2 Random Forest (adopted from https://www.researchgate.net/figure/Architecture-of-random-forest_fig3_375437347)

C. Network Architecture for Support Vector Machine

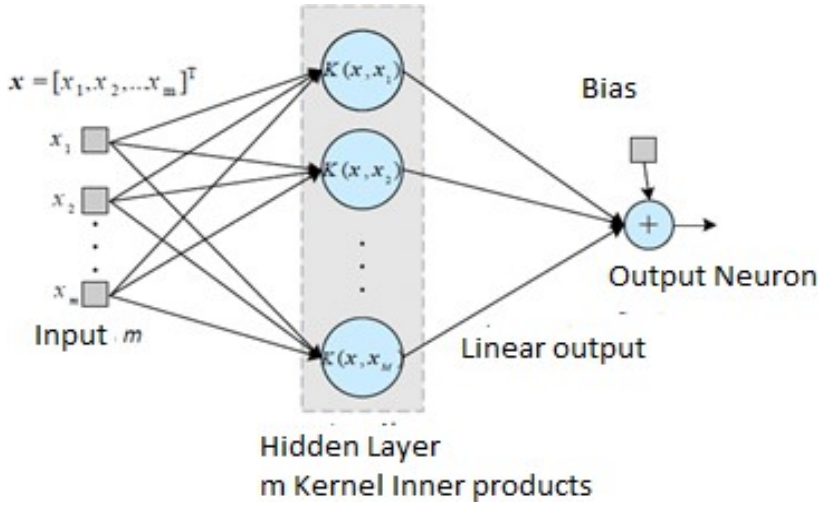

Fig 3.3: Support Vector Machine (adopted from https://www.researchgate.net/figure/Support-Vector-Machine-Architecture)

To comprehend proposed model, Specialist can think about a model situation: a client might approach information gathered from various areas. IoT gadgets are associated with the IoT entryways at various areas. Admittance to the information is just permitted after the information channel at the canny edge passage. The doors gather the information and offer piece of the information with distributed storage. In some utilization cases, client end-gadget applications access the information from the edge doors.

3.2 Tools utilized in the Execution.

Here are the devices utilized in carrying out this examination:

Programming Dialects:

i. Python: Python is generally utilized in AI research and gives a rich environment of libraries, for example, TensorFlow, PyTorch, and scikit-realize, which can be utilized for executing protection saving AI calculations.

Information Examination, Representation and Graphical UI:

i. Anaconda Pilot IDE: this is a GUI for boa constrictor dissemination that permits clients to send off applications and oversee conda conditions and sending off bundles for information representation

ii. Jupyter Note: is an online intelligent improvement climate, especially known for its note pad highlight. It is intended to work with the creation and sharing of records that contain live code, conditions, representations, and story message.

3.1.2 System Requirements

Hardware and software component used are as follows:

Hardware Component	**Specification**
Processor	Intel Core i7
Processor Speed	2.60 GHz
Memory (RAM)	8.00 GB
Software Component	**Specification**
Operating System (OS)	Windows 10 64bit
Anaconda IDE(Jupiter Note)	3.6.13
Python	

Microsoft Excel(CSV)	2010

Table 3.1: System Requirement

3.1.3 System Algorithm

Stage 1: Characterize the issue: Characterize your desired issue to settle

Stage 2: Assemble and preprocess the information C. That is, gather a bunch of information pertinent to the issue and preprocess them by resizing, normalizing, and enlarging on a case by case basis.

Stage 3: Plan the brain network engineering, Arbitrary Woodland and Backing Vector Machine

Stage 4: Split the preprocessed information into preparing, approval, and testing sets.

Stage 5: Train the organization and models

Stage 6: Assess the models:

Stage 7: Convey the framework

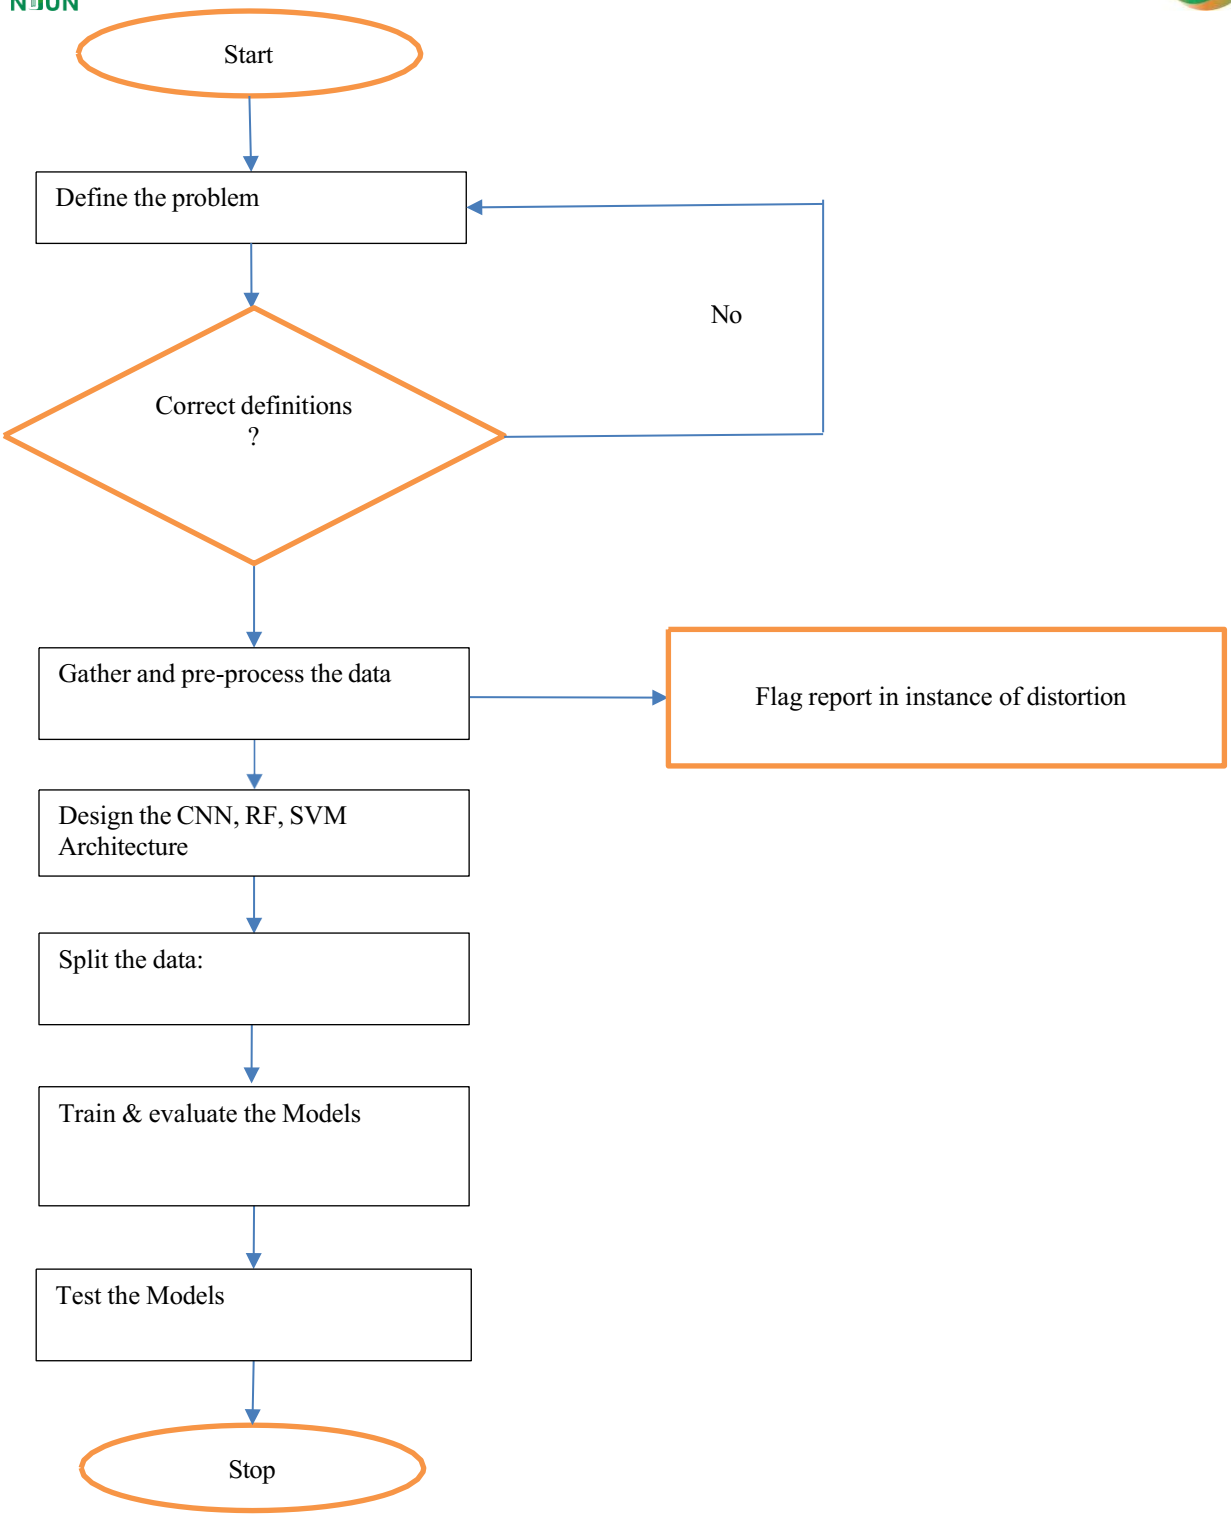

Figure 3.4: System Flow Chart

The system flowchart highlights the activities in the entire system and provides a quick and pictured summary on the operability of the system.

3.2 Approach and Technique(s) for the proposed solution

There are a few IoT information security gambles at various IoT worldview layers. To tackle the issue referenced over, this study incorporates the plan for another model which will be a wise model for upgrading protection in IoT-based frameworks.

3.2.1 Dataset Utilized

IoT-based movement acknowledgment datasets is gathered from Kaggle which contain sensor information from different IoT gadgets. The gathered information will go through preprocessing to eliminate commotion, exceptions, and superfluous highlights. Security safeguarding methods, for example, information anonymization and encryption, will be applied to safeguard individual protection.

Table 3.2: intrusion Dataset (source: https://www.kaggle.com)

3.5.3 Functional and Non-Functional Requirements

The functional requirement of this framework is connected with business processes that:

i. Should recognize interruption on the security of the IOT organization

ii. The framework ought to have the option to take choice by means of expectations

iii. The application ought to have the option to identify dangers utilizing elements and target,

Non-utilitarian necessities for this framework are:

i. Users ought to see as the created model simple and viable.

ii. Tracking movement component, so that administrator can assess risks or circles on the framework.

iii. High handling speed, since this component will impact clients' enthusiasm in utilizing this framework

3.5.4 Program Coding

Advancement apparatuses used to execute this framework is open-source python as programming language. The IDE utilized is jupyter note. Coding is the main move toward the plan of the whole framework; this is on the grounds that it is the system of the plan. A portion of the targets of making program determinations are to guarantee that the program fulfills client data prerequisites and in particular convenience.

To plan an itemized framework, the examination of how the framework would be executed was placed into thought, hence the course of framework execution was broken into modules and sub-modules. This is known as the Hierarchical methodology; the justification for this is a direct result of its benefit of speedy mistake recognition and troubleshooting that prompts great programming rationale. Having said this, the programming language utilized in the plan of the proposed framework is the Python programming language which is a cutting edge and flexible programming language which suits the reason this undertaking properly.

3.3 Research Plan including Exploration Interaction Bound together Demonstrating Language (UML)

In this model, IoT administrations and applications will be limited at the edge gadgets and inside the distributed computing layer. IoT gadgets inside a particular area move information to the closest edge gateway(s). The smart edge door will just impart part of the gathered information to the cloud gadgets. The spatiality of the edge gadgets will be information separating prior to moving information to the cloud. The edge IoT gadgets will be answerable for information conglomeration and handling and information stockpiling too. In this proposed model, the end-client IoT applications will impart to the cloud servers to get to information or data handled at the cloud gadgets. In certain situations, the IoT end-client applications ought to have the option to get to the edge doors straightforwardly. This model will improve the IoT information security and protection by restricting administrations and decreasing information move between the IoT entryways and the cloud gadgets.

For appropriately Improving Information Security in the IoT, a savvy entryway confirms clients' personality and approval prior to permitting admittance to any information source. It could happen that gatecrashers gained admittance to the IoT passages. Thus, it is fundamental to have private information separated before the gatecrasher obtains entrance.

The smart IoT doors need to distinguish delicate individual data with the goal that the confidential information can be arranged. In such cases, shrewd doors will utilize AI calculations to arrange information and sources. As AI calculations require more assets and the edge doors might have impediments, so Analyst propose Backing Vector Machine as the AI calculation. Yet, at the underlying stage, the AI calculation won't have an adequate number of information to foresee client action. Thus, a standard based classifier can be utilized for information and source/client classification at the underlying stage. Rule based arrangement can be performed with not very many stages/steps. Fig. 2 addresses various strides for rule-based arrangement.

Fig. 3.5. Steps for rule-based categorization.

3.3 Description of validation technique(s) for proposed solution

To approve the proposed answer for the review, the accompanying approval strategies will be utilized:

Dataset Assortment Approval:

Information Quality Evaluation: Scientist will play out an exhaustive appraisal of the gathered dataset to guarantee its quality and dependability. Check for missing qualities, anomalies, and irregularities that could influence the exploration results.

Dataset Representativeness: The analyst will assess the dataset's representativeness by contrasting it and existing writing and space information. Guarantee that it covers a different scope of exercises, conditions, and sensor types pertinent to IoT-based action acknowledgment.

Formal Demonstrating Approval:

Hypothetical Structure Assessment: The specialist will direct a basic assessment of the hypothetical systems and calculations proposed for Irregular Timberland and Convolutionary Brain Organizations (RF and CNN) with Help Vector Model (SVM) as classifier, likewise survey the sufficiency of the establishments, confirmations, and hypothetical ensures given by these systems.

Security Conservation Appraisal: The analyst will confirm the degree to which the proposed differential protection systems save security by investigating their numerical properties and guaranteeing they meet the necessary security limits and assurances.

Numerical Demonstrating Approval:

Protection Examination Affirmation: Approve the numerical investigation and confirmations related with the security saving strategies. Confirm the exactness of the security limits and ensures given by differential protection, guaranteeing that the additional commotion or annoyance fulfills the ideal security prerequisites.

Security Investigation Check: Approve the security properties of the proposed secure collection methods through numerical examination and confirmations. Affirm the privacy, honesty, and genuineness ensures given by the cryptographic conventions used.

Recreation Systems Approval:

Recreated Climate Approval: Survey the legitimacy and authenticity of the mimicked IoT climate utilized for assessing the proposed procedures. Guarantee that the reproduction precisely mirrors the attributes and ways of behaving of true IoT-based action acknowledgment frameworks.

Execution Appraisal: Assess the exhibition of the proposed protection saving methods inside the reproduced climate. Measure exactness, protection conservation, and utility measurements to approve the adequacy of the procedures under various situations and conditions.

By utilizing these approval methods, scientists can guarantee the unwavering quality, adequacy, and generalizability of the proposed answer for upgrading protection saving AI for IoT-based movement acknowledgment. The approval cycle approves the examination procedure, guaranteeing the precision of the outcomes and giving trust in the ends drawn from the review.

3.4 Description of Execution Assessment Measurements

To survey the exhibition of each model, Analyst utilized the most utilized execution measurements, like exactness, accuracy, review, and F-score measurements as displayed in the accompanying conditions:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\text{Precision} = \frac{TP}{TP + FP}$$

$$\text{Recall} = \frac{TP}{TP + FN1}$$

$$\text{F1-score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

Where true positive (TP) and true negative (TN) represent the correctly predicted values, and false positive (FP) and false negative (FN) indicate misclassified events.

3.4 System Architecture

The system architecture for the models used is shown below:

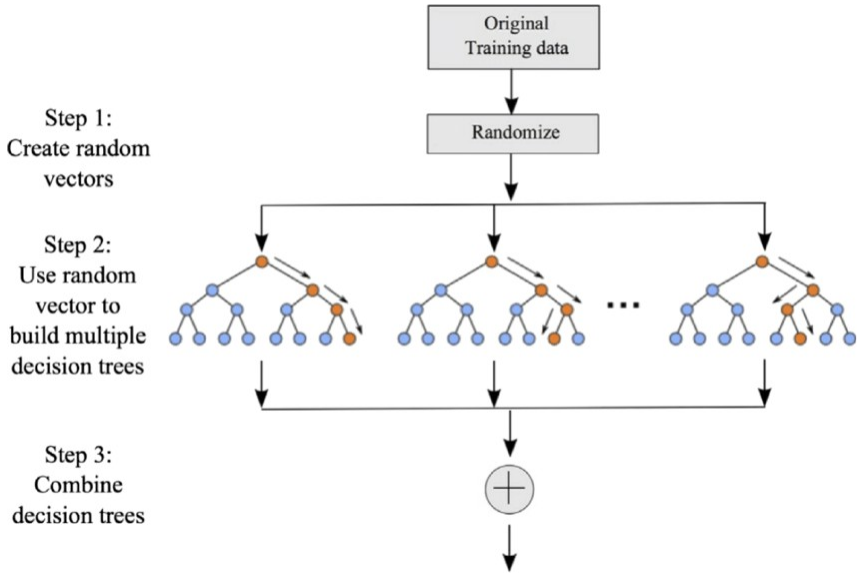

Fig 3.6: Block diagram for random forest

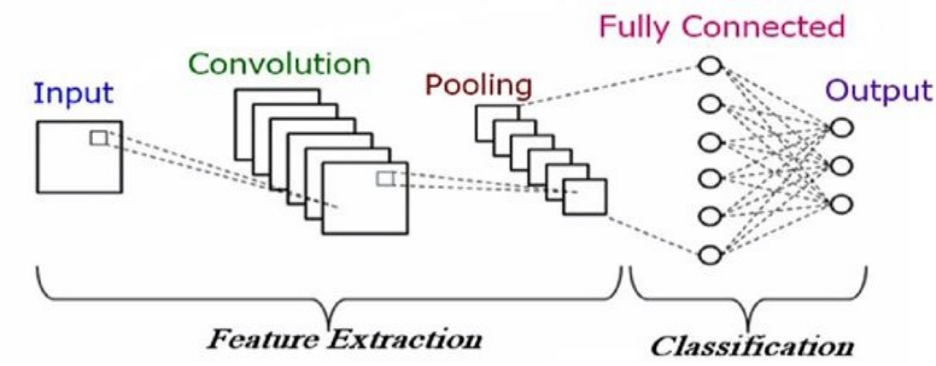

Fig 3.7: Block diagram for Convolutional Neural Networks

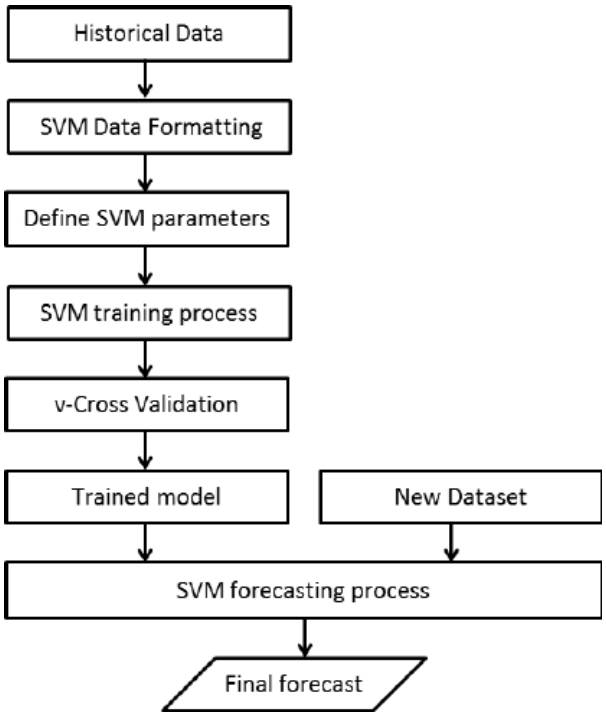

Fig 3.8: Block diagram for Support Vector Machine

CHAPTER FOUR
RESULTS AND DISCUSSION

4.1 Preamble

This part portrays the tests did inside this examination work and furthermore presents the outcomes likewise. The review tends to the developing worry of security breaks and unapproved admittance to delicate information with regards to the Web of Things (IoT). By utilizing trend setting innovations and keen methods, the RF-CNN model means to moderate protection dangers and improve the general security of IoT frameworks. All through this conversation, Scientist will dig into the vital discoveries and ramifications of the review, revealing insight into the viability and relevance of the proposed wise model. The conversation will address a few parts of the review, including the plan and execution of the model, the assessment strategy utilized, and the outcomes got.

Besides, this conversation will feature the ramifications of the discoveries in the more extensive setting of IoT security and protection. Analyst will consider the expected advantages and difficulties related with the reception of the proposed model, as well as its true capacity for mix into existing IoT foundations. The review's discoveries will add to the current collection of information in the field of IoT security and security, offering important bits of knowledge for scientists, specialists, and chiefs looking to improve protection assurances in IoT-based frameworks.

4.2 System Assessment

An exhaustive assessment of RF, CNN and SVM includes a mix of quantitative measurements and subjective bits of knowledge. Understanding the qualities and shortcomings of each model with regards to the particular application will assist with directing the determination and improvement of AI frameworks. This framework will be assessed with Exactness which is the extent of right expectations to add up to forecasts, the Accuracy which is the quantity of genuine positive expectations partitioned by the quantity of genuine positive and misleading positive expectations. The Review (Awareness): The quantity of genuine positive expectations isolated by the quantity of genuine positive and misleading negative forecasts. The F1 Score which is the symphonious mean of accuracy and review, valuable for imbalanced classes. The Disarray Network: A table that sums up evident versus anticipated orders, giving experiences into explicit mistakes.

4.3 Results Show

4.3.1 Datasets Depiction

Datasets are compulsory for preparing and assessing Interruption Identification Frameworks in IoT organizations. The choice of the suitable datasets for a particular undertaking is likewise critical. The datasets utilized in this

examination is IOT based dataset from Kaggle. The CSV document is then imported and fought. The libraries are additionally imported for utilization in the IDE

```
import pandas as pd
from sklearn.model_selection import train_test_split
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import classification_report, confusion_matrix

df = pd.read_csv("dataset_invade.csv")

df
```

	duration	protocol_type	service	flag	src_bytes	dst_bytes	land	wrong_fragment	urgent	hot	...	serror_rate	rerror_rate	same_srv_rate	diff_srv_rate
0	0	tcp	ftp_data	SF	491	0	0	0	0	0	...	0.0	0.0	1.00	0.00
1	0	udp	other	SF	146	0	0	0	0	0	...	0.0	0.0	0.08	0.15
2	0	tcp	private	S0	0	0	0	0	0	0	...	1.0	0.0	0.05	0.07
3	0	tcp	http	SF	232	8153	0	0	0	0	...	0.2	0.0	1.00	0.00
4	0	tcp	http	SF	199	420	0	0	0	0	...	0.0	0.0	1.00	0.00
...	...	...	...	...	...	...	...	...	...	...	...	...	...	...	...
148512	0	tcp	smtp	SF	794	333	0	0	0	0	...	0.0	0.0	1.00	0.00
148513	0	tcp	http	SF	317	938	0	0	0	0	...	0.0	0.0	1.00	0.00
148514	0	tcp	http	SF	54540	8314	0	0	0	2	...	0.0	0.0	1.00	0.00
148515	0	udp	domain_u	SF	42	42	0	0	0	0	...	0.0	0.0	1.00	0.00
148516	0	tcp	sunrpc	REJ	0	0	0	0	0	0	...	0.0	1.0	0.25	1.00

1.3.2 Coding and data Wrangling

a. Creating column arrays and view the NAN status of the dataset

```
[131]: df.columns
```

```
[131]: Index(['duration', 'protocol_type', 'service', 'flag', 'src_bytes',
       'dst_bytes', 'land', 'wrong_fragment', 'urgent', 'hot', 'logged_in',
       'num_compromised', 'count', 'srv_count', 'serror_rate', 'rerror_rate',
       'same_srv_rate', 'diff_srv_rate', 'srv_diff_host_rate',
       'dst_host_count', 'dst_host_srv_count', 'dst_host_same_srv_rate',
       'dst_host_diff_srv_rate', 'attack'],
      dtype='object')
```

b. View the NAN status of the dataset

```
[133]: df.isnull().sum()
```

```
[133]: duration                    0
       protocol_type               0
       service                     0
       flag                        0
       src_bytes                   0
       dst_bytes                   0
       land                        0
       wrong_fragment              0
       urgent                      0
       hot                         0
       logged_in                   0
       num_compromised             0
       count                       0
       srv_count                   0
       serror_rate                 0
       rerror_rate                 0
       same_srv_rate               0
       diff_srv_rate               0
       srv_diff_host_rate          0
       dst_host_count              0
       dst_host_srv_count          0
       dst_host_same_srv_rate      0
       dst_host_diff_srv_rate      0
       attack                      0
```

c. Data Pre-Processing

```
# Preprocessing
# Convert categorical variables to numerical using one-hot encoding
df = pd.get_dummies(df, columns=['protocol_type', 'service', 'flag'], drop_first=True)

# Map the target variable
df['attack'] = df['attack'].map({'No': 0, 'Yes': 1})

# Split the dataset into features and target variable
X = df.drop('attack', axis=1) #this drops the attack column, leaving the rest of the features
y = df['attack']  #this is the discretised target
```

```
# Split the data into training and testing sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)

# Create a Random Forest Classifier
rf_classifier = RandomForestClassifier(n_estimators=100, random_state=42)

# Train the model
rf_classifier.fit(X_train, y_train)

# Make predictions
y_pred = rf_classifier.predict(X_test)

# Evaluate the model
print(classification_report(y_test, y_pred))
```

```
# Confusion Matrix Visualization
cm = confusion_matrix(y_test, y_pred)
plt.figure(figsize=(8, 6))
sns.heatmap(cm, annot=True, fmt='d', cmap='Blues', xticklabels=['No Attack', 'Attack'], yticklabels=['No Attack', 'Attack'])
plt.xlabel('Predicted')
plt.ylabel('True')
plt.title('Confusion Matrix')
plt.show()

# Feature Importance Visualization
importances = rf_classifier.feature_importances_
feature_names = X.columns
feature_importance_df = pd.DataFrame({'Feature': feature_names, 'Importance': importances}).sort_values(by='Importance', ascending=False)

plt.figure(figsize=(12, 8))
sns.barplot(x='Importance', y='Feature', data=feature_importance_df)
plt.title('Feature Importances')
plt.xlabel('Importance Score')
plt.ylabel('Features')
plt.show()
```

d. Importing Models for CNN

```
import pandas as pd
import numpy as np
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler, LabelEncoder
from tensorflow.keras import layers, models
from tensorflow.keras.utils import to_categorical
from sklearn.metrics import classification_report, confusion_matrix
```

e. Neural Network Epochs

```
Epoch 1/10
8/8 ━━━━━━━━━━━━━━━━━━━━ 4s 7ms/step - accuracy: 0.5397 - loss: 0.7092

```

4.2 Analysis of Results

4.2.1 Performance Metrics

There are some parameters on the basis of which we can evaluate the performance of the classifiers which are explained below.

i. **The Accuracy** of a classifier on a given test set is the percentage of test set tuples that are correctly classified by the classifier.

ii. **The Error Rate** or misclassification rate of a classifier, M, which is 1-Acc (M), where Acc (M) is the accuracy of M.

iii. **The Confusion Matrix** is a useful tool for analyzing how well the classifier can recognize tuples of different classes.

iv. **The Mean Absolute Error (MAE)** is the average of all absolute errors.

v. **Root Mean Square Error (RMSE)** is the standard deviation of the residuals (prediction errors). Residuals are a measure of how far from the regression line data points are; RMSE is a measure of how spread out these residuals are. In other words, it tells you how concentrated the data is around the line of best fit.

vi. **The sensitivity** and **specificity** measures can be used to calculate accuracy of classifiers. **Sensitivity** is also referred to as the true positive rate (the proportion of positive tuples that are correctly identified), while **Specificity** is the true negative rate (that is, the proportion of negative tuples that are correctly identified). These measures are defined as follows:

$$\text{Sensitivity} = \frac{\text{t-pos}}{\text{pos}}$$

$$\text{Specificity} = \frac{\text{t-neg}}{\text{neg}}$$

$$\text{Precision} = \frac{\text{t-pos}}{\text{t-pos} + \text{f-pos}}$$

where:

t-pos = number of true positives tuples that were correctly classified

pos = number of positive tuples

t-neg = number of true negative tuples that were correctly classified

neg = number of negative tuples

f-pos = number of the false positive tuples that were incorrectly labeled

Thus, it can be shown that the performance accuracy of a classifier is a function of sensitivity and specificity

Hence,

$$\text{Accuracy} = \text{Sensitivity}\left(\frac{\text{pos}}{\text{pos} + \text{neg}}\right) + \text{Specificity}\left(\frac{\text{neg}}{\text{pos} + \text{neg}}\right)$$

The above stated performances measures are explained below:

TP Rate: It is the proportion of actual positives which are predicted as positive. The formula is defining as:

$$\text{TP Rate} = \frac{t_p}{(t_p + f_n)}$$ where t_p stands for true positive and f_n stands for false negative

FP Rate: It is the rate of negatives tuples that are incorrectly labeled. The formula is defined as

FP Rate of class Yes = $\frac{f_n}{(f_n + t_n)}$

FP Rate of class No = $\frac{f_p}{(t_p + t_p)}$

Cohen's kappa statistic is a very good measure that can handle very well both multi-class and imbalanced class problems.

Cohen's kappa is defined as:

$$\kappa = \frac{p_o - p_e}{1 - p_e} = 1 - \frac{1 - p_o}{1 - p_e},$$

Where:

p_o is the observed agreement, and p_e is the expected agreement. It basically tells you how much better your classifier is performing over the performance of a classifier that simply guesses at random according to the frequency of each class.

The **Mean Absolute Error** (MAE) is the average of all absolute errors. The formula is:

$$\mathrm{MAE} = \frac{1}{n}\sum_{i=1}^{n} |x_i - x|$$

Where:

n = the number of errors,

Σ = summation symbol (which means "add them all up"),

$|x_i - x|$ = the absolute errors.

Root Mean Square Error is commonly used in climatology, forecasting, and regression analysis to verify experimental results.

The formula is:

$$RMSE = \sqrt{(f - o)^2}$$

Where:

f = forecasts (expected values or unknown results),

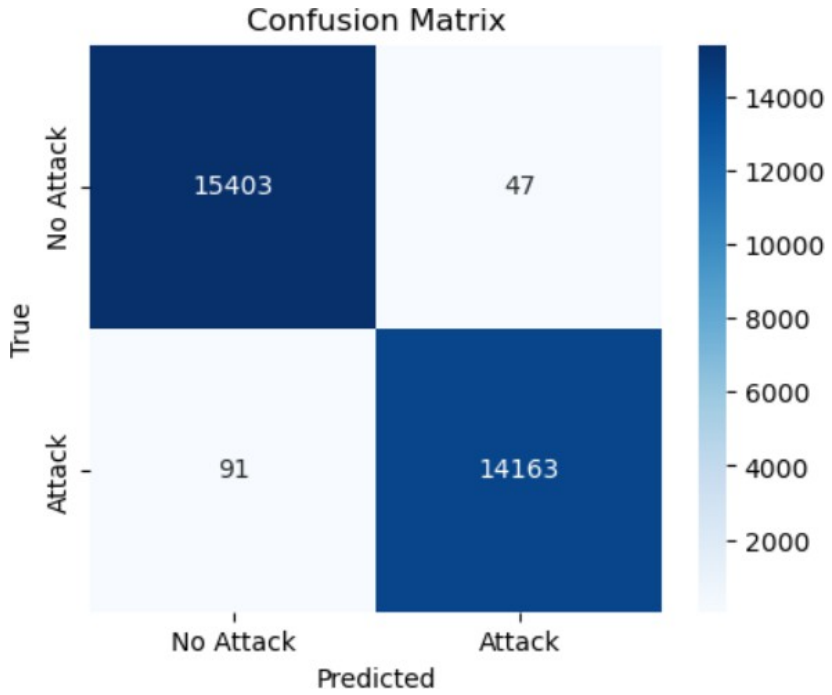
o = observed values (known results).

4.2.2 Performance Evaluation Metrics Presentation for Random Forest

	precision	recall	f1-score	support
0	0.99	1.00	1.00	15450
1	1.00	0.99	1.00	14254
accuracy			1.00	29704
macro avg	1.00	1.00	1.00	29704
weighted avg	1.00	1.00	1.00	29704

```
[15]: y_pred

[15]: array([0, 0, 0, ..., 0, 1, 0], dtype=int64)
```



True Negatives (TN) = 15,403: The model correctly predicted 15,403 instances as negative that no attack happened on the instances.

False Positives (FP) = 47: The model incorrectly predicted 47 instances as positive when they were actually negative that that no attack happened on the instances.

False Negatives (FN) = 91: The model incorrectly predicted 91 instances as negative when they were actually positive, that attack happened on the instances.

True Positives (TP) = 14,163: The model correctly predicted 14,163 instances as positive that attack happened on the instances.

4.2.3 Performance Evaluation Metrics Presentation for SVM

```
Classification Report:

```

4.3 Discussion of Results.

4.3.1 Results Discussion for Random Forest

The Irregular Woods Classifier was assessed on a dataset for paired grouping (assault versus no assault), yielding profoundly great outcomes across various measurements. The grouping report gives nitty gritty bits of knowledge into the model's exhibition, featuring its viability in recognizing the two classes. Generally speaking Exactness of 100 percent (29,704 examples accurately grouped) the model accomplished amazing precision, implying that each case in the test set was accurately characterized.

Accuracy Class 0 methods No Assault (0.99). Class 1 method Assault (1.00). Accuracy estimates the exactness of positive expectations: For Class 0, the accuracy of 0.99 demonstrates that the vast majority of occasions anticipated as "No Assault" were for sure right, with just 1% being bogus up-sides. For Class 1, an accuracy of 1.00 demonstrates that all anticipated assaults were real assaults. This recommends that the model is truly dependable in distinguishing assaults when it predicts them, making it a valuable device for limiting phony problems.

Review estimates the model's capacity to recognize every single pertinent occasion: A review of 1.00 for Class 0 demonstrates that the model effectively distinguished all occurrences of "No Assault," missing none (i.e., no misleading negatives). A review of 0.99 for Class 1 proposes that the model recognized the vast majority of genuine assaults, with just 1% of assaults being missed. This is areas of strength for a, demonstrating that the model is compelling in catching the vast majority of the significant positive examples.

The F1-Score is the consonant mean of accuracy and review, offering a solitary metric that adjusts both: A F1-score of 1.00 for the two classes imply wonderful accuracy and review. This shows that the model is exceptionally successful, as it accurately distinguishes assaults as well as does as such with insignificant misleading up-sides and negatives.

Support Class 0 (No Assault): 15,450 occasions, Class 1 (Assault): 14,254 cases. Support demonstrates the real number of events in each class inside the test set: The model was prepared and tried on a reasonable arrangement of classes, with a somewhat bigger number of "No Assault" examples. The large number of tests furnishes the model with a hearty reason for learning the examples related with each class.

Large scale and Weighted Midpoints: Full scale Avg: Accuracy, Review, and F1-Score = 1.00, Weighted Avg: Accuracy, Review, and F1-Score = 1.00. Both large scale and weighted midpoints are likewise great, showing that the model keeps up with major areas of strength for its across classes, paying little heed to class conveyance. This supports trust in the model's unwavering quality and power.

Overall Metrics:

- **Accuracy:** 1.00 — the model correctly classified 100% of all instances.
- **Macro Average:**
  - **Precision:** 1.00 — Perfect precision across classes.
  - **Recall:** 1.00 — Perfect recall across classes.
  - **F1-score:** 1.00 — Perfect F1-score across classes.
- **Weighted Average:** Similar to macro averages, but it accounts for the support of each class, leading to:
  - **Precision:** 1.00

- **Recall:** 1.00
- **F1-score:** 1.00

In outline, the Arbitrary Woods Classifier has shown remarkable execution in grouping assaults versus non-assaults, with wonderful accuracy, review, and F1-scores. These outcomes feature the model's adequacy in both distinguishing significant cases and limiting bogus up-sides. Notwithstanding, further approval on different datasets and extra examination is prescribed to guarantee the heartiness and generalizability of the model in true applications.

4.3.2 Results Conversation for SVM

Accuracy for "NO" (0.60): Out of all occasions anticipated as "NO", 60% were in fact "NO". This shows that there were a few misleading up-sides (cases that were as a matter of fact "YES" yet anticipated as "NO").
Accuracy for "YES" (0.60): Comparably, for occurrences anticipated as "YES", 60% were in fact "YES". This again focuses to a few bogus up-sides in this class. Accuracy demonstrates the dependability of positive expectations. An accuracy of 0.60 recommends that there is critical opportunity to get better in accurately distinguishing positive occasions without misclassifying negatives.
Review for "NO" (0.60): Of all genuine "NO" occasions, 60% were accurately anticipated as "NO". This implies that 40% of "NO" occasions were mistakenly delegated "YES" (bogus negatives). Review for "YES" (0.60): For the genuine "YES" occasions, 60% were accurately recognized. Once more, this implies that 40% were missed (bogus negatives). Review mirrors the model's capacity to catch every single important occasion. A review of 0.60 shows that the model is feeling the loss of a huge piece of the genuine good cases, which can be basic in applications where misleading negatives are exorbitant.
F1-Score for the two classes (0.60): The F1-score is the symphonious mean of accuracy and review. It gives a harmony between the two, especially valuable when you have imbalanced classes. A score of
0.60 proposes that the model isn't performing great generally, as both accuracy and review are moderately low.
Support for the two classes (5): This demonstrates that there were 5 occasions of each class ("NO" and "YES") in the test dataset.
Generally speaking Exactness (0.60): This demonstrates that the model accurately anticipated 60% of the all out occurrences in the test set. While this could appear to be adequate in certain unique circumstances, in numerous applications, particularly those with basic results (like extortion identification or clinical determinations), this degree of precision might be lacking.

4.3.3 Results Conversation for CNN

This CNN order report gives a nitty gritty outline of the model's presentation across two classes (0 and 1). Here is a breakdown of the measurements:

Class 0:
Accuracy (0.62) Out of completely anticipated class 0 cases, 62% were right. Review (1.00) the model accurately recognized all genuine class 0 examples. F1-score (0.77) the consonant method for accuracy and review, adjusting the two measurements. Support (5) there are 5 real examples of class 0 in the dataset.
Class 1:
Accuracy (1.00) All anticipated class 1 occasions were right. Review (0.40). The model just recognized 40% of genuine class 1 occurrences. F1-score (0.57) demonstrates a compromise among accuracy and review for this class. Support (5) there are 5 real cases of class 1 in the dataset.
In general Measurements:

- Accuracy: 0.70 — the model accurately ordered 70% of all occurrences.
- Macro Normal:
  - Accuracy: 0.81 — Normal accuracy across classes.
  - Review: 0.70 — Normal review across classes.

- F1-score: 0.67 — Normal F1-score across classes.
- Weighted Normal: Like large scale midpoints, yet it represents the help of each class, prompting:
- Accuracy: 0.81
- Review: 0.70
- F1-score: 0.67

Class 0 is being anticipated well indeed (high review), yet the model battles with Class 1 (low review). The high accuracy for Class 1 recommends that when the model predicts Class 1, it's normally right, yet it misses a ton of genuine Class 1 examples.

4.4 Implication of Results

Irregular Woodland (RF) has an exactness of 100 percent on 148,517 examples. This is an amazing exhibition, however likely worries about overfitting or information spillage ought to be explored. Support Vector Machine (SVM) has exactness of 60% on 50 occasions. This implies moderate execution; may require more information or better boundary tuning to further develop results. Convolutional Brain Organization (CNN) has exactness of 70% on 50 examples. This Beats SVM on a similar little dataset, showing better component extraction capacities. RF is obviously the best entertainer here on the dataset and infers that it is good for creation

4.5 Benchmark of Results

The benchmark of results from the examination of the three models; Irregular Woodland, Backing Vector Machine (SVM), and Convolutional Brain Organization (CNN) is summed up in the accompanying table and conversation. This benchmark features the qualities and shortcomings of each model concerning exactness, accuracy, review, and F1-score.

Metric	Random Forest	Support Vector Machine	Convolutional Neural Network
Accuracy	100%	60%	70%
Precision (Class 0)	0.99	0.60	0.62
Precision (Class 1)	1.00	0.60	1.00
Recall (Class 0)	1.00	0.60	1.00
Recall (Class 1)	0.99	0.60	0.40
F1-Score (Class 0)	1.00	0.60	0.77
F1-Score (Class 1)	1.00	0.60	0.57

Table 4.1: Benchmark of Results

The benchmark results plainly delineates the qualities of the Arbitrary Woodland model in accomplishing amazing order execution. Conversely, both SVM and CNN exhibit difficulties that require consideration, especially in working on their capacity to limit misleading negatives and improve generally unwavering quality.

It is critical to take note of that a past comparable review embraced the k-closest neighbor AI based Prescient Examination in Medical care IoT (Hariharan V., 2023) with a better than expected outcome as Accuracy: 91.6%, review: 92.35%, F1-score: 92% and a general exactness of 98.4%. This outcome offers a close to consummate

generally exactness contrasted with the outcome accomplished in this work. Irregular Woodland has been found to perform better compared to other ML models across the various situations. In the 2-Class task, all of the ML models perform with a precision of ≥ 98%, while it diminishes with expanding intricacy of the issue. There is a slight improvement in exactness for the ML models prepared in the decreased component for example 0.06% in RF and DNN models. (MM Khan, 2024)

Future work ought to zero in on refining the SVM and CNN models through highlight designing, hyperparameter tuning, and potentially gathering procedures to lift their presentation nearer to that of the Arbitrary Woodland Classifier.

CHAPTER FIVE
SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Summary

This paper examines security challenges in the quickly extending domain of Web of Things (IoT) frameworks, proposing a clever model using AI methods to upgrade information assurance. The review centers around the adequacy of Arbitrary Timberland, Backing Vector Machine (SVM), and Convolutional Brain Organization (CNN) calculations in arranging network traffic as either an assault or non-assault. The exploration included a few key parts:

Writing Survey: The exposition analyzed existing works connected with IoT protection, existing Security Improving Advances, Computational strategies, AI models that add to information security, recognizing holes in current approaches and the requirement for successful security safeguarding methods.

System: An organized methodology was taken on, starting with dataset procurement from Kaggle, trailed by information preprocessing, highlight extraction, and model choice. The picked models were thoroughly prepared and assessed.

Results: The outcomes demonstrated that the Irregular Woods model accomplished wonderful precision (100 percent) in grouping assaults and non-assaults. Interestingly, SVM and CNN showed moderate execution, with precision paces of 60% and 70%, individually. The examination uncovered qualities and shortcomings in each model, accentuating Irregular Woodland's unrivaled ability in limiting bogus up-sides and negatives.

5.2 Conclusion

The concentrate effectively shows the significance of utilizing progressed AI methods to address protection worries in IoT frameworks. The discoveries highlight the capability of the Irregular Woodland model as a hearty answer for interruption discovery, given its uncommon execution in characterization undertakings. On the other hand, the SVM and CNN models, while showing guarantee, require further refinement to improve their prescient capacities. The exploration adds to the scholastic talk on IoT security by offering bits of knowledge into the viability of different AI draws near and their materialness in genuine situations. It underlines the basic harmony between keeping up with client security and guaranteeing the

utility of IoT frameworks.

5.3 Recommendations

In light of the discoveries of this exploration, a few suggestions are proposed for reasonable executions: Investigate extra elements that might work on model execution, especially for SVM and CNN, direct methodical enhancement of hyperparameters to refine model precision and unwavering quality, Investigate Outfit Techniques. Explore the utilization of group strategies that consolidate numerous models to use their assets, possibly further developing in general arrangement precision. Carry out the models in genuine IoT conditions to evaluate their commonsense adequacy and strength against fluctuated assault vectors. Likewise, use different datasets that incorporate a more extensive scope of IoT applications and situations to improve model preparation and generalizability.

5.4 Contributions to Information

This paper makes a few critical commitments to the field of IoT security and protection, upgrading the comprehension of AI applications in shielding delicate information. The key commitments are illustrated as follows:

Improvement of a Savvy Model: The exploration presents a hearty model that use progressed AI methods — explicitly Irregular Backwoods, Backing Vector Machines (SVM), and Convolutional Brain Organizations (CNN) — to successfully address protection challenges in IoT frameworks. This model fills in as a reasonable structure for upgrading protection from unapproved access and information breaks.

Exact Examination of AI Methods: The relative assessment of the three AI calculations gives important bits of knowledge into their assets and shortcomings with regards to interruption location. The discoveries feature the extraordinary presentation of the Arbitrary Backwoods model, adding to the writing by showing its viability in limiting bogus up-sides and expanding identification rates.

Structure for Future Exploration: The review lays out a basic system for future examination on protection safeguarding AI methods in IoT conditions. By distinguishing likely regions for development, for example, include designing and hyperparameter tuning, the exploration prepares for resulting examinations that could improve the relevance and unwavering quality of these models.

Down to earth Experiences for Industry Partners: The discoveries offer significant bits of knowledge for industry specialists, engineers, and policymakers engaged with IoT framework plan and sending. By framing successful procedures for security protection, the examination adds to the definition of best practices that can illuminate more secure and more dependable IoT arrangements.

Coordination of Protection Safeguarding Procedures: The proposition accentuates the significance of incorporating security saving philosophies, like differential security and unified learning, into AI models. This commitment tends to the earnest requirement for procedures that upgrade security as well as keep up with the utility of IoT frameworks.

Commitment to Strategy Advancement: By giving proof based proposals, this exploration upholds policymakers in creating administrative structures and rules pointed toward further developing information security in IoT conditions. The discoveries feature the requirement for strategies that energize the reception of security improving advances.

Tending to Holes in Existing Writing: The review fills basic holes in the scholarly writing in regards to the convergence of IoT protection, AI, and information security. By investigating the viability of various calculations in genuine situations, it improves the talk on security challenges looked by IoT frameworks.

Hybridization of RF-CNN models: The blend of RF and CNN consolidates their particular assets to address explicit difficulties looked by existing frameworks. The RF calculation succeeds in taking care of organized information and component choice, while CNNs are capable at handling unstructured information, like pictures and time series, considering the extraction of complicated designs. By consolidating these methodologies, the half breed model can altogether diminish high misleading positive rates, further develop grouping exactness, and upgrade adaptability and proficiency in handling huge volumes of IoT information. Besides, this cross breed RF-CNN model empowers continuous handling and quick navigation, which are basic in powerful conditions requiring prompt reactions to security dangers. In general, this imaginative methodology not just reinforces protection safeguarding and power against different assaults yet additionally gives significant experiences and adds to the group of information in growing more refined and viable security answers for IoT frameworks.

In rundown, this postulation essentially progresses the assortment of information in IoT security and protection, giving both hypothetical bits of knowledge and reasonable arrangements that can upgrade the security of IoT applications in different settings.

5.2 Future Exploration Headings

Expanding on the discoveries and restrictions of this review, a few roads for future exploration in the space of IoT security and protection can be investigated:

Half breed AI Models: Examining crossover moves toward that join different AI calculations, for example, incorporating Arbitrary Backwoods with profound learning strategies like Convolutional Brain Organizations (CNNs), could further develop arrangement execution and upgrade the capacity to identify complex assault designs.

Continuous Protection Safeguarding Strategies: Exploring strategies to carry out constant security saving procedures in IoT conditions, like unified learning and nearby differential security, can address the difficulties of handling enormous volumes of information while keeping up with client security.

Ill-disposed AI: Investigating the ramifications of antagonistic assaults on AI models in IoT settings can assist with growing more vigorous frameworks. Understanding how these assaults can control model execution will be significant for reinforcing safety efforts.

Client Driven Protection Arrangements: Future examinations could zero in on creating client driven security arrangements that engage people to control their information in IoT conditions. This might include making easy to use interfaces for overseeing protection settings and grasping information use.

Cross-Area Applications: Analyzing the appropriateness of the created models and procedures across various IoT spaces (e.g., shrewd homes, medical care, modern IoT) will give experiences into the generalizability and flexibility of security improving arrangements.

Longitudinal Examinations: Directing longitudinal investigations to assess the drawn out viability of security safeguarding methods and AI models in unique IoT conditions can offer important bits of knowledge into their supportability and development.

Blockchain Reconciliation: Researching the coordination of blockchain innovation with IoT frameworks for improved security and protection could guarantee. Investigating decentralized approaches for information the executives and protection certifications might offer imaginative arrangements.

Effect of Guidelines on IoT Security: Examining the impacts of advancing information insurance guidelines (e.g., GDPR) on IoT security practices will give significant bits of knowledge into consistence challenges and the adequacy of existing measures.

Client Conduct Examination: Exploring client conduct examination in IoT conditions can help in growing more customized and setting mindful protection arrangements, improving both client experience and information security.

Improved Information Administration Structures: Future exploration can zero in on laying out complete information

administration structures that framework best practices for information assortment, stockpiling, and partaking in IoT frameworks, guaranteeing moral and capable information utilization.

By chasing after these headings, scientists can add to the continuous improvement of compelling protection and security arrangements that address the intricacies of IoT conditions, at last cultivating a safer and protection mindful mechanical scene.

ENHANCING E-GOVERNANCE INTEROPERABILITY IN THE CONTEXT OF E-LEARNING AND MANAGEMENT INFORMATION SYSTEM

By

MUHAMMAD ABDULSALAM

(ACE21130007)

M.Sc Management Information System

Africa Center of Excellence on Technology Enhanced Learning (ACETEL) of

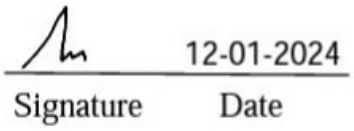
National Open University of Nigeria

November, 2023

DECLARATION

I sincerely wish to state that this research work was written by me under the guidance and supervision of the department of Management Information System, Africa Center of Excellence on Technology Enhanced Learning. This work is entirely mine and I accept the responsibility for any error that might occur in the write-up. However, I also wish to acknowledge the contribution of various authors stated in this research work.

Muhammad Abdulsalam



Signature Date

CERTIFICATION

This is to certify that the research work recorded was carried by: Muhammad Abdulsalam ACE21130007 of the department of Management Information System, Africa Center of Excellence on Technology Enhance Learning (ACETEL) of the National Open University of Nigeria.

Under the supervision of:

Dr. Ibrahim Abdullahi

Project Supervisor 1

Signature Date

Dr. Naeem Balogun

Project Supervisor 2

Signature Date

DEDICATION

This research work is dedicated to Almighty ALLAH for giving me the Knowledge and understanding needed.

ACKNOWLEDGEMENT

My utmost appreciation goes to Almighty ALLAH, for giving me the most expensive opportunity to be among the living and more also to study at ACETEL.

I wish to extend my profound gratitude to my supervisors, Dr. Ibrahim Abdullahi and Dr. Naeem Atanda Balogun who took their time despite their tight schedules to go through my thesis work with constructive advice, guidance and corrections in order to improve the quality of this research, to this end I pray and salute their courage.

My profound gratitude goes to my respected and lovely parent Mr. & Mrs. A. Abdulsalam. I also wish to extend my heartfelt gratitude to my beloved elder sisters, Rabi & Safiya and the entire family of Abdulsalam for their prayers, encouragement and financial support.

Special appreciation to my beloved and caring wife for her support and encouragement.

May Almighty ALLAH reward them all.

CHAPTER THREE: RESEARCH METHODOLOGY

CHAPTER FOUR: DATA ANALYSIS AND INTERPRETATION

CHAPTER FIVE: SUMMARY, CONCLUSION AND RECOMMENDATION

List of Tables

ABSTRACT

In the 21st century, most nations across the globe are embracing e-government systems in order to effectively govern and encourage their citizens to participate in a good and rapid development. As an emerging nation, Nigeria experiences the most rapid growth in the information and communication technology industry within Africa in terms of financial technology and yet it struggles to provide e-government services to its citizens, thereby promoting and striving for citizen-centric, connected, networked and integrated governance. Therefore, this research study aims to capture and understand how e-governance interoperability can be enhanced through the context of e-learning and management information system. This is a descriptive type of research which used the survey research technique, using a structured questionnaire and observation method to determine e-learning and management information systems to improve the interoperability of e-government.

However, Samples were collected from employees of the National Information Technology Development Agency (NITDA) of Nigeria. The collected data were analyzed using a frequency table, percentage and mean scores, while a non-parametric statistical test (Chi-square) was used to test the hypothesis formulated at the 5% significance level to reveal the influence of e-Learning and management information systems on e-governance interoperability. It was concluded that e-learning and management information systems are important for improving e-governance interoperability, and they are greatly helpful in organizational collaboration and contribute to bringing an integrated information flow within the organization. With the help of management information system, governments can easily produce, analyze, disseminate and process information across ministries and department. In addition, e-learning has the potential to meet the

growing challenges by enhancing the possible way to provide adequate experience and knowledge to citizens and employees.

CHAPTER ONE

INTRODUCTION

1.1 Background of the Study

In the modern era, most nations across the globe are embracing electronic government systems in order to effectively govern and encourage their citizens to participate in a good and rapid development. E-governance refers to the delivery of governmental services to the public by utilizing digital technology. According to Izhar-ud-Din (2017) "e-governance means the utilization of the internet and world wide web(www) for the transfer of information and delivery of services from the government to citizens" (Izhar-ud-Din & Xue, 2017). electronic governance is characterized as the conveyance of public administration and data to the open by utilizing digital implies (Ilyas, 2016). The primary goal of e-governance is to strengthen the competence and effectiveness of the administration as well as to promote people's participation. This research thesis is set out to assess the enhancing of e-governance interoperability in the context of e-learning and management information systems (MIS). The application of e-governance is rapidly growing globally among developing and developed countries (Alshehri et al., 2021). The utilization of e-government has become a crucial mechanism for enhancing citizen engagement, overseeing and assessing government programs, guaranteeing government responsibility and openness, and facilitating the exchange of information between different parties (Adah and Abasilim, 2015).

Many developing nations encounter difficulties when implementing e-governance into their systems, and in some cases, it is not successful. E-government initiatives in developing nations are unsuccessful or discontinued due to their inability to achieve the intended objectives (Heeks, 2003). Nigeria, being an emerging nation, experiences the most rapid growth in the information and communication technology industry within Africa in terms of financial technology and yet

faced issues in providing e-governance services to its citizens as a result, it is fostering its effort to a more citizens centered, connected, network and integrated governance. However, most government initiatives do not interact and exchange data with one another to achieve expected results due to the facts that they are not interoperable. E-Government seems to be further along as Ministries, Departments and Agencies (MDAs) develop and deploy new Information and Communication Technology (ICT) systems with solutions and specifications that suit their voluntary needs without sufficient consideration of the need for connectivity, collaborate, share, exchange and reuse information with other information and communication technology (ICT) systems.

E-Learning is regarded as national information infrastructure as well as part of national e-governace. The role of e-learning is imperative to e-governace systems and its citizens, Daniel (2009) “observe that e-learning plays an important role in professional development for adults in the workforce”. As most countries are fostering to achieve their developmental values, it is safe to conclude that e-learning has the potential to meet the growing challenges. Apart from professional development benefits, another benefit of e-learning is that it is effective and accommodates everyone's needs. To enhance people's participation in e-governance, the government, policy makers and the public need to have a better understanding of e-learning.

The implementation of Management Information Systems as an Information system makes use of Information Communication Technology to collect, analyse and communicate information an organization adopt for operations (Laudon and Landon, 2017). It is an information system which are used for collection, analyzing, processing, accumulating and communicating information that are essential for managerial processes, functions and decision-making (Odusanya, 2019). Olalekan (2014) opines Management Information Systems as an information communication technology

which focus is to improve communication necessary for fostering management roles, processes and Establish a connection between the organization and its surrounding external environment (Olalekan, 2014). The description emphasized that management information systems goal is to enhance communication and connect organization with their external environment.

1.2 Statement of the Problem

In this digital era, most developing nations in the world are moving toward e-governance systems in order to improve their status as a digital country but are faced with challenges of successful information sharing, communication, collaboration, interaction, decision making and policy management within e-governance initiatives due to the fact that the systems are not interoperable. The assurance of e-governance looks more secluded because ministries, departments and agencies are designing, developing, deploying and updating new information communication technology systems with conditions, provisions, solutions and qualifications applicable to their peculiar needs without adequate consideration to the need to connect, share, exchange and re-use data with other Information Communication Technology systems.

However, e-learning plays a role in e-governance interoperability by providing e-governance initiatives and the public adequate knowledge and understanding of how to enhance the interoperability of e-government systems as well as management information systems (MIS) are foster towards enhancing e-governance interoperability. Since e-learning and management information systems (MIS) will significantly have a notable impact on e-governance interoperability. It is therefore, important for one to study the current practice of e-learning and management information systems in the Nigerian agency, National Information Technology Development Agency (NITDA).

1.3 Aim of the Study

This research study aims to capture and understand how e-governance interoperability can be enhanced through the context of e-learning and management information system (MIS).

1.4 Objectives of the Study

The goals of the research study are outlined below:

i. To examine the issues associated with e-governance systems interoperability.
ii. To determine how e-governance interoperability can be enhanced by management information systems (MIS).
iii. To find out if e-learning will improve people's participation in e-governance systems.

1.5 Research Questions

The study was designed with the following research questions.

i. What are the issues associated with e-governance interoperability?
ii. How can e-governance interoperability be enhanced by management information systems (MIS)?
iii. How can e-learning improve people's participation in e-governance?

1.6 Research Hypotheses

Hypothesis I

H_0: There is no significant relationship between Management Information Systems (MIS) and enhancing e-governance interoperability.

H_i: There is a significant relationship between Management Information Systems (MIS) and enhancing e-governance interoperability.

Hypothesis II

H_0: There is no significant relationship between Management Information Systems (MIS) and e-governance goal.

H_i: There is a significant relationship between Management Information Systems (MIS) and e-governance goal.

Hypothesis III

H_0: There is no significant relationship between e-learning and e-governance.

H_i: There is a significant relationship between e-learning and e-governance.

1.7 Scope of the Study

This essay examines the enhancement of e-government interoperability within an organization through the context of e-learning and management information systems (MIS). The case study used is the National Information Technology Development Agency (NITDA) in Nigeria. In addition, the thesis is conducted with department heads and employees of the organization. The aim is to study the existing e-learning as well as management information systems practices used within the organization from the point of view of organizational interoperability. There will always be significant differences and idiosyncrasies between these governmental organizations due to their unique history, culture and norms. Therefore, the findings of the research cannot be applied to or assumed to be true for other comparable organizations.

1.8 Significance of the Study

This research study adds information and can serve as a guide for other studies, it has a huge number of advantages:

Students: Students should see the need to equip and utilize knowledge of Management Information System (MIS) in modern technologies to suit e-government interoperability.

Government: It is hoped that the results of this essay will provide the government with ready tools to create a unified e-government framework that connects individuals and other participants in public administration.

Learning Institutions: Institutions are expected to take advantage of the educational needs and importance of their students in a modern Management Information System (MIS) and integrate it into their learning experience for adequate e-government interoperability.

Future Scholars: This long essay, once completed, will be useful to future scholars by providing them with reference material.

1.9 Definition of Terms

E-learning: is the utilization of contemporary technology tools like computers, digital devices, online platforms and related software to facilitate learning processes. They are learning experiences and learning content that are enabled or produced by modern technology.

MIS stands for Management Information Systems: is a hardware and software computer system that acts as the backbone of organization and operations.

Interoperability: the ability of various e-government initiatives from different ministries, departments and agencies to communicate, interpret and exchange information in an integrated way of providing public services.

Government Digital Transformation (GDT) refers to the modernization of government processes through the implementation of technology, also known as Advanced Whole of Government (WoG): This implies that the Nigerian government is undergoing a change through the use of ICT in order to provide services and empower its citizens. The government aims to be transparent and efficient, with the ultimate objective of achieving sustainable economic, political, and social improvements in the country.

Service: is an activity that is clearly defined and carried out by government ministries, departments, and agencies to offer assistance and support to stakeholders within their authority. This assistance is provided using modern technology tools such as information and communication technology to ensure efficient delivery.

1.10 Organization of the Thesis

This thesis is divided into a total of five individual chapters. The text consists of an introduction, a review of the existing literature on the topic, an explanation of the research methodology used, the presentation and analysis of the results, and finally a conclusion.

Chapter 1 provides an overview of the master's thesis. To begin with, the text provides an overview of the background information, research problem, research questions, and hypothesis. Next, the study's goals, objectives, and limitations were clarified. Third, the importance of the research was mentioned. Ultimately, a clarification of concepts.

Chapter 2. In this part of the text, the work developing the theoretical basis of the thesis is presented. First, it introduces a search strategy for relevant literature and publications. Next, the main ideas of the literature review examine the key concepts that provide the theoretical foundation for the Master's thesis. These include e-learning, management information systems, e-governance,

and the e-governance interoperability. Afterwards, the theoretical framework of resource-based theory is introduced, and it is utilized to examine and explore the findings of the research. Finally, it concludes with the review of related works.

Chapter 3 provides an explanation and conversation about the different approaches and strategies utilized in the research to gather and examine data as considered suitable. Initially, the text provides information about the research design and the participant group involved in the study. Following that, it introduces various samples and methods of sampling, explores the research instrument, examines the instrument's validity and reliability. In conclusion, it ends with the methods of collecting data and analyzing data.

Chapter 4 discusses the way the findings acquired from the questionnaires are displayed and examined. Afterwards, the data that had been gathered were organized based on their ranking in the research questions. A basic percentage was employed to examine the demographic information of the participants, while the study hypothesis was assessed using the chi-square test.

Chapter 5 present the thesis summary which discuss the research priorities and processes, then it also covers the conclusion of the research findings and offers recommendations based on those findings. Afterward, the presentation focused on the research's contribution. Finally, recommendations for further investigation were presented.

CHAPTER TWO
LITERATURE REVIEW

2.1 Introduction

In this part of the text, the work developing the theoretical foundation of the thesis is presented. First, it introduces a search strategy for relevant literature and publications. Next, the main ideas of the literature review examine the key concepts that provide the theoretical foundation for the Master's thesis. These include e-learning, management information systems, e-governance, and the e-governance interoperability. Afterwards, the theoretical framework of resource-based theory is introduced, and it is utilized to examine and explore the findings of the research. Finally, it concludes with the review of related works.

2.2 Search Strategy

A detailed searching and review of research articles for this study was carried out from academic journals on e-governance, e-learning and management information systems which were published between 2011 and 2023. E-governance, e-learning, interoperability, management information system, developing countries, Nigeria are the keywords used to search for articles. The databases which were used for the keywords searches includes Scopus, Springer link, IEEE Xplore, ACM, JSTOR, Gale OneFile and Google Scholar.

2.3 Literature Review

2.3.1 E-learning

E-learning has become the foundation of knowledge as well as education in most nations as the world is moving to digital era. Horton (2015) provided a definition for e-learning as the utilization of the internet and digital technologies in order to deliver educational experiences to people. It involves the use of digital technologies to create both online and offline learning experiences on

the web, ultimately facilitating human learning. E-learning is an independent educational setting in which the learners possess autonomy and self-control over the conditions of their learning and study at their own pace and convenience (Eke, 2017).

E-learning has been existing for over 40 years in the form of distance learning such as radio and televised courses, and is rapidly developing in form of open and distance learning. Looking at e-learning from a different prospective compared to distance learning, it encompasses various technologies such as ICTs, internets, websites, networks, and other electronic platforms that are used to enhance learning and teaching in other to convey skills and knowledge (Kasse & Balunywa, 2013). Parks (2013) "recommended that “e-” must mean “everything, everyone, enticing and easy” in annexation to ‘electronic". E-learning is a general term that describes educational technologies that support learning and teaching electronically or through technology (Wikipedia, 2014). E-learning can advance social integration and consideration, opening doors to learning for individuals with special/extraordinary needs and those living in troublesome circumstances. Modern e-learning arrangements recognize the significance of learning as a social handle, advertising conceivable outcomes for collaboration with other learners, for interaction with the substance and for direction from instructors, coaches and guides. These learn-centered approaches put the learners back in control with easy access to as many learning assets and resources as they need.

Numerous organizations have adopted e-learning as a famous studying methodology to meet the demands of continuous learning worldwide, regardless of the location of learners (Sandars, 2021). According to (Wang et al., 2021) E-learning has the capability to improve management communication, employee training and efficiency more than any other online program, making it an excellent solution. E-learning is the best solution for organizations looking to take their learning

and development programs to the next level (Asch et al., 2017). Daniel (2009) seen that e-learning plays a vital part in proficient advancement for grown-ups within the workforce. As most countries are fostering to achieve their developmental values, it is safe to conclude that e-learning has the potential to meet the growing challenges. E-learning is the best possible way to provide adequate experience and knowledge to learners at their own pace.

2.3.2 Management Information System

Management Information System is a communication medium that improve information flow and managerial functions in an organization. According to (Sipior, 2017) A management information system is primarily based totally on records era and features typically to convert uncooked records from inner and outside reasserts into records that is also used to formulate reports which help different departments of an organization to make better and more informed decisions. Management information systems are data communication innovations outlined to upgrade the communication essential for bonding management roles, administration parts, processes, forms and the organization to the outside environment (Olalekan, 2014). Management Information systems can also be view as a communication medium that ensure managerial functions, processes and roles are feasible.

MIS are unified mechanisms that collects, process, analyze and share information that are key to development and achieving organizational objectives. Specific company desires consisting of enhancing marketplace position, constructing new products, or introducing new services, enhancing productivity, amongst others can't be carried out without choicest statistics systems (Laudon and Laudon, 2017). Management information systems are technologies developed to manage and automate previously traditional, rule-based decision-making processes of thumb,

intuition, and personal experience medium" (Laudon and Laudon, 2017). This traditional approach is not fit for fast developing organizations in this digital era. This brought about the improvement of management information system (Laudon and Laudon, 2017). The Vital role of Management Information Systems in e-governance system has proficiency and tendency to be an essential and vital part of e-governance interoperability in order to connect, share exchange and re-use data with other e-governance initiatives.

Sipior (2017) opines that MIS is "an integrated technology for collecting, processing, classifying, storing and distributing information". Management information systems contain information about key people, systems and environments inside and outside the organization (Sipior, 2017). According to Siering and Janze (2019) An MIS may be a computer-based and manual framework which changes information into pertinent data fundamental to giving the bolster vital for making right decisions. MIS is a place where “the planning and integration of systems are carried out for the collection of relevant information, transforming it into the right data that can be supplied to executives at different levels which aids at providing the right information at the right time to interested personnel of the information” (Siering and Janze, 2019).

Management information systems permit governments to easily create, analyze, share, distribute, and manipulate information across departments and agencies (Anastasiadou et al., 2021). Also, information and communication technology are utilized to meet the needs and aspirations of e-government. Technologies such as particular open division entries and stages, web administrations that serve the necessities for both government and citizens, and the utilization of websites and social systems that increment the involvement of the citizens (Anastasiadou et al., 2021).

The most preferences of utilizing management information system in e-governance are to bolster the democratic decision-making process, facilitate citizen activities and enable citizen participation (Anastasiadou, Santos and Montargil, 2021). Management information systems improve citizen participation in communication with the government. It gives individuals and groups of people greater access to information that allows them to influence public policy (Anastasiadou, Santos and Montargil, 2021). By utilizing management information systems, citizens can more easily and effectively participate in the decision-making process and also, the open communication sessions allow better cooperation with local people to assist the government center on fathoming neighborhood issues (Anastasiadou, Santos, & Montargil, 2021).

In e-government, governments can use management information system platforms to understand the level of work and implementation of projects, and citizens can use this program to see current and ongoing programs that affect their voting demographics (Mohammed, et al., 2017). Management information systems help allocate resources to approved projects, organize monitoring and implementation teams, projects can be distributed based on the needs of citizens (Mohammed, et. al., 2017).

2.3.3 E-governance

Electronic governance has become the foundation of most countries in the world as almost every government have key into e-governance system in order to efficiently and effectively govern and encourage its citizens involvement for a good and fast development. Izhar-ud-Din (2017) opines that "e-governance means the utilization of the internet and world wide web(www) for the transfer of information and delivery of services from the government to citizens" (Izhar Ud Din & Xue, 2017).

Adah (2015) opines e-governance as a double-way communication process which ensures the availability and delivery of public services to the citizens through the use of ICT. The term e-governance is seen by Attah-Ullah (2021) as Electronic governance, stands for electronic administration. It is the integration of information and communication technology (ICT) in all activities to increase the ability of the government to respond to the demands of the local public (Attah-Ullah Ullah, 2021). Thus, e-governance is the use of electronic resources to deliver government information and services to the people (Ilyas, 2016). The aimed of e-governance is the provision of effective and efficient government services delivery and enhance it accessibility to the citizens.

Dhamodharam & Saminathan (2011) defined e-governance as the use of information communication technology (ICT) means such as websites, internet and online applications by the government to improve access and delivery of services and information to government initiatives as well as its citizens. Abasilim and Edet (2015) stated that "e-governance is a progressive movement from the traditional method of carrying out government businesses which is mainly a hierarchical, Linear and one-way model. But for the governance, the use of the internet enables the public seeks information at their own convenience and nor really having to visit the office in person or when the government office is open". It is of great benefits to the citizens as it connects them to the government more easily. The government provides services to various clients such as citizens, businesses and government employees, each service differs according to the needs of the client. The services of the e-government are government-to-government (G2G), government-to-business (G2B), government-to-employee (G2E) and government-to-citizen (G2C).

E-government alludes to the advancement of unused open services and benefit conveyance models that utilize computerized technologies and government and citizen data frameworks assets

(Oumkaltoum et al., 2021). Government investment of e-government administration without citizen participation may not deliver the guaranteed benefits (Napitupulu et al. al., 2019). On the other side, the government can avail from e-Government administrations by upgrading communication with the open (Vicente and Novo, 2014), advancing straightforwardness in administration (Elbahnasawy, 2014), and progressing the conveyance of government-related administrations. Also, governments profit from enhanced communication with their open, which subsequently empowers straightforwardness in government (Ghassan et al., 2021).

2.3.4 E-governance Interoperability

E-governance Interoperability is the ability of different e-governace system initiatives from various ministries, department and agencies to interact by communicating, interpreting and exchanging information in an integrated way to deliver public services. Interoperability has many definitions. Interoperability is the ability of more than one system to communicate and exchange data with each other to achieve expected outcome by a clearly prescribed means (Van Staden & Mbale, 2012). Kirilova (2015) opines that e-governance interoperability is " the ability of different systems from various stakeholders of e-governance to work together, by communicating, interpreting and exchanging the information in a meaningful ways". Besides the connectivity of the stakeholders, interoperability also identifies potential tools to enable ideal e-governace services to its different stakeholders by aiding systems integration, information sharing and cross-boundary collaboration (Ipinge & Nengomasha, 2018). Ipinge & Nengomasha (2018) also posit "the vital objective in e-governance systems is to enhance government administrations and provide services to different stakeholders" (Ipinge & Nengomasha, 2018).

However, the fact today is that most developing nations have key into e-governance system but yet face challenges as a result of not able to interoperate among government initiatives when developing individual e-services. Interoperability is vital for government initiatives to connect, share, exchange and re-use data with each other. In essence, Interoperability is an absolutely requisite for the development of effective and efficient e-government services at all levels (local, state, national and international level).

The three level of interoperability will be considered:

- organizational interoperability: This level of interoperability determines the effective and efficient management and implementation of the processes needed for the provision of collaborative services between two or more organizations. Its goal is to address any feasible hindrance to the collaboration of services such as public service structure, process management, data right issues and ICT requirements etc.
- Semantic interoperability: This aspect of interoperability is seen as the Fundamental to the integration and enhancing the quality of e-governance services. It aims is to ensure the meaning of the exchanged data or information is understood by other applications which were not basically designed for that purpose.
- Technical interoperability: This aspect of interoperability examines the hardware and software issues. It deals with the technological issues of linking computer systems with the services such as interconnection services, data presentation and exchange, interface specifications and security systems etc.

Sulehat and Taib (2016) noted that the interoperability system includes two components to be specific, obstructions preventing the execution of government management information system

and success variables. The boundaries preventing e-governance management information system as distinguished by Sulehat and Taib (2016) incorporate destitute ICT foundation, destitute administration support, need of specialized abilities, security concerns, information and data integration issues, and trade forms. On the other side, Sulehat and Taib (2016) talk about critical success components for actualizing management information system for e-governance which incorporate collaboration between administrative bodies. Sulehat and Taib (2016) moreover, famous that collaboration between the administrative bodies can be guaranteed by having common e-governance interoperability objectives and aims, engagement of administrative bodies, and having customer focus.

Finally, Sulehat and Taib (2016) famous that the model benefits and points of interest involved the demonstrate incorporate viability, productivity, and straightforwardness through a strong commitment from the organization and administration as well as fetched decrease and returns on venture through private-public organization for progressing responsiveness, lessening duplication and diminishing costs (Sulehat and Taib 2016). However, the integration and interoperability with different structures ought to be a Key to efficaciously offer complete administration to all at one place (Dutta et al., 2017).

2.4 Theoretical Framework

The Resource-based theory (RBT) is a theory that manage the organization's resources to attain a sustainable and competitive advantage (Barney & Hesterly, 2015). RBT has been used generally to analyze resources in the field of management to achieve competitive advantage (Barney, Ketchen & Wright, 2011). Many academic experts such as Penrose 1959), Lippmann and Tumelt (1982), wernerfelt (1984), and Dierickx and cool (1989) have all discuss the concept of

Resource-based theory in its early dawn. However, Barney (1991) designed the RBT shape remarkably by explaining the resource features of competitive advantage. Assets are resources of accessible components of generation possessed or controlled by an organization (Amit and Schoemaker, 1993). Capabilities in respect to resources, can be seen as the ability of an organization to utilize resources through its process (Amit & Schoemaker, 1993). Furthermore, Capabilities is referring to the ability of a group of resources to accomplish certain activity or duty (Barney, 1991), and that are frequently produced to connect human, physical and technology resources in functional and sub-functional area (Amit & Schoemaker, 1993).

E-learning and Management Information Systems as resources from RBT perspective, that are exceptional, rare and valuable which can produce positive outcome. Technology assets for example networks, websites and database management systems could not probably produce positive outcomes because they could be acquired easily (Barney, 1991). Nevertheless, integrating computer systems with the software's and services systems can lead to a smooth, flexible and refine IT infrastructure that will be unique since producing such caliber of infrastructure needs carefully integrating technology components to fit the needs and preferences of the organization (Amit & Schoemaker, 1993).

In the resource-based theory, it is believed that no organization can produce all the resources needed for its functions and operations. However, it is must cooperate with other Key actors and organizations in its environment. Similarly, (Eze, Adelekan and Nwaba, 2019) also opined that limiting resources at the organizational level gives a limited picture because information systems cross organizational boundaries. Hence, it is more sensitive to the dynamic effects of intermittent and cataclysmic environmental change (Eze, Adelekan, & Nwaba, 2019). Therefore, an

organization must be able to satisfy relevant stakeholders such as shareholders, customers and employees.

The purpose of this master's thesis is to understand the importance of e-learning and management information systems as a critical resource to enhance e-governance interoperability. Therefore, in this thesis, resource-based theory is found as a suitable lens to see and understand the results of this thesis. The paper uses resource-based theory to understand how resources should be managed in collaboration with other key actors such as citizens, businesses, other administrative bodies and workers.

2.5 Review of Related Works

Boluwatife (2019) studied the transformation of education through e-learning and its management for national development in Oyo state, Nigeria. The study was a descriptive type which explore how e-learning and its management can transform education for the benefit of national development in Oyo state, Nigeria. The findings showed that e-learning can really transform education. It was concluded that e-learning is a tool that can be used to improve and facilitate the teaching and learning process in schools.

In recent years, a quantitative approach has been used to evaluate the effectiveness of management information systems of business organizations. Boluwaji and Opeyemi (2020) investigated the impact of management information systems on the performance of business organizations in Nigeria. The findings by Boluwaji and Opeyem (2020) reveals the factors hindering the development of management information systems in Nigeria. The results of the findings show that weak funding, poor technological infrastructure and tools, unfavorable government policies, lack

of innovation. These factors reduce the organization's ability to compete in the global market by developing a flexible management information system (Boluwaji and Opeyemi, 2020).

Ramesh, Vivekavardhan, and Bharathi (2015) examined the challenges of successfully implementing e-government interoperability in Nigeria. They point out the strong opposition from the bureaucratic parts of politics as the first major obstacle. Ramesh, Vivekavardhan, and Bharathi (2015) identify this by arguing that overburdened civil service members may perceive e-government policies as an attempt by the government to reduce the number of jobs. Other issues and challenges include lack of integrated policies and programs, lack of common and common solutions to common problems, failure to promote common infrastructure and applications, failure to take advantage of the relative advantages of different agencies and maximize the value of e-government investments and technical people skills, and resources to manage ICT infrastructures and tools, high costs for acquiring ICT infrastructures and tools, and staff training. Furthermore, Ramesh, Vivekavardhan and Bharathi (2015) also stated that another major challenge as lack of adequate and steady power supply in the nation as ICT infrastructures require regular power supply. However, the use of generators is not always effective in providing sufficient power for ICT equipment. Other studies, for example, highlight barriers to e-government adoption in Nigeria. In accordance with the study, barriers to e-Governance implementation and system interoperability in Nigeria are the same as in other developing countries.

In addition, Ajibade et al. (2017) also argued that the technical framework for e-government implementation in Nigeria is below standard. Similarly, Adisa et al. (2017) further highlight obstacles such as poor telecommunications and internet services. Other major challenges are poor ICT facilities, digital divide, weak electricity supply and weak technical know-how. However,

there is very little or limited similar research on how e-learning and management information system can enhance e-governance interoperability.

CHAPTER THREE

RESEARCH METHODOLOGY

3.1 Introduction

This chapter provides an explanation and conversation about the different approaches and strategies utilized in the research to gather and examine data as considered suitable. Initially, the text provides information about the research design and the participant group involved in the study. Following that, it introduces various samples and methods of sampling, explores the research instrument, examines the instrument's validity and reliability. In conclusion, it ends with the methods of collecting data and analyzing data.

3.2 Research Design

A survey research design was espoused for the research study. The choice of plan was influenced by the objectives of the study presented in Chapter 1. This study design provides a quick, efficient and accurate way to evaluate data from the population of interest. It aims to study e-learning with management information systems in enhancing interoperability of e-governance systems in an organization. The study will be conducted in Nigeria.

3.3 Population of the Study

The participants in this study were employees of National Information Technology Development Agency (NITDA). This organization was selected because the organization is a leading e-government enabler in Nigeria and provides IT and shared services to the Nigerian government. A total of 60 respondents were selected from the population on which the sample size was

determined. These study participants were selected because they have good work experience in obtaining productive material.

3.4 Sample and Sampling Techniques

The researcher used Taro Yamane's formula to determine the population sample size.

Taro Yamane's formula is:

$$n = \frac{N}{1+N\,(e)2}$$

Where N = Population of study (60)

n = Sample size (?)

e = Level of significance at 5% (0.05)

1 = Constant

$$\therefore \quad n = \frac{60}{1 + 60\,(0.05)2} = \frac{60}{1+60\,(0.0025)} = \frac{60}{1+0.15}$$

$$n = \frac{60}{1.15} = 52$$

Therefore, the sample size is 52 respondents.

3.5 Research Instrument and Instrumentation

Data for this research were collected from essential and auxiliary sources. The main source of data collected was mostly through the use of a structured questionnaire aimed at obtaining information on e-learning with management information systems in enhancing interoperability of e-governance systems in an organization. Secondary data collection sources were textbooks, journals and scientific materials.

3.6 Validity of Instrument

The instrument in this study underwent face validation. Face validation tests the relevance of questionnaire items. This is because face validation is often used to show if the instrument in front of you appears to measure what it contains. The purpose of face validation is therefore to determine how relevant the questionnaire is to the objectives of the study. If the instrument is sent for face validation, the supervisors will validate copies of the original draft of the questionnaire. The supervisors are expected to critically examine the points of the instrument with the specific objectives of the study and make useful suggestions to improve the quality of the instrument. Based on his recommendations, the instrument is adjusted and readjusted before being submitted for examination.

3.7 Reliability of Instrument

The coefficient of reliability was considered to be 0.8, because according to Etuk (1990), a test-retest coefficient of 0.5 is sufficient to justify the use of a research instrument.

3.8 Method of Data Collection

This study is based on two possible sources of data which are primary and secondary.

1. **Primary Data Source:** The primary data for this study consists of raw data obtained from questionnaire responses and interviews with the respondents.
2. **Secondary Data Source:** Secondary data includes information obtained from the review of literature such as journals, monographs, textbooks and other journals.

3.9 Method of Data Analysis

The collected data will be analyzed using a frequency table, percentage and mean scores, while a non-parametric statistical test (Chi-square) was used to test the formulated hypothesis at the 5% significance level. Respondents have four response options. Strongly agree scored:4, agree scored: 3, disagree scored: 2, and strongly disagree: 1. After collecting data using a questionnaire, it is coded, tabulated and analyzed using SPSS statistical software according to the research question and hypothesis. To effectively analyze the collected data, the chi-square method is used in testing independence for easy control and accuracy.

Chi square is given as

$$X2 = \frac{\sum (o-e)2}{e}$$

Where; X2 = chi square

o = observed frequency

e = expected frequency

Degree of Freedom / Level of Confidence

A certain confidence level or margin of error must be assumed when using the chi-square test. In addition, the degree of freedom in the simple variable, row and column distribution of the table must be determined, the degree of freedom is: df = (r-1) (c-1)

Where; df = degree of freedom

r = number of rows

c = number of columns.

When determining the critical chi-square value, a confidence value of 95% or 0.95 is assumed. The margin for error in judgment is 5% or 0.05.

CHAPTER FOUR

DATA ANALYSIS AND INTERPRETATION

4.1 Introduction

This chapter discusses the way the findings acquired from the questionnaires are displayed and examined. Afterwards, the data that had been gathered were organized based on their ranking in the research questions. A basic percentage was employed to examine the demographic information of the participants, while the study hypothesis was assessed using the chi-square test.

4.2 Analysis of Respondents' Demographic Data

Table 1: Gender of Respondents

Gender	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Male	36	69.2308	69.2308
Female	16	30.7692	100
TOTAL	52	100	

Table 1 above shows the gender distribution of the respondents used in this study. Out of all 52 respondents, 36 respondents are men, or 69.2316 percent of the population. 16, representing 30.7696 percent of the population, are women.

Table 2: Professional / Work Experience of Respondents

EXPERIENCE	FREQUENCY	PERCENT	CUMULATIVE PERCENT
1-5 years	23	44	44
6-10 years	12	23	67

11-15 years	9	17	84
16-20 years	5	10	94
Above 20 years	3	6	100
TOTAL	52	100	

Table 2 above shows the professional/work experience of the respondents used in this study. Out of all 52 respondents, 23 respondents, which constitute 44 percent of the population, have 1-5 years of professional/work experience. 12 respondents, which make up 23 percent of the population, have 6-10 years of work experience. Nine respondents, representing 17 percent of the population, have 11 to 15 years of work experience. Five respondents, representing 10 percent of the population, have 16-20 years of professional/work experience. Three respondents, representing 6 percent of the population, have more than 20 years of professional/work experience.

Table 3: Eligibility of Respondents

QUALIFICATION	FREQUENCY	PERCENT	CUMULATIVE PERCENT
SSCE/NECO/WAEC	7	13.46	13.46
NCE/OND	13	25.00	38.46
HND/BSC	16	30.77	69.23
PGD/MSc	11	21.15	90.38
PhD	5	9.62	100
TOTAL	52	100	

Table 3 above shows the eligibility of the respondents used in this study. Out of 52 respondents, 7 respondents representing 13.46 percent of the population are holders of SSCE/NECO/WAEC. 13

representing 25.00 percent of the population are NCE/OND holders. 16, representing 30.77 percent of the population, are HND/BSc holders. 11, representing 21.15 percent of the population, are PGD/MSc holders. 5, representing 9.62 percent of the population, had a PhD type of education.

Table 4: Department of the Respondents

DEPARTMENT	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Human Resource and Administration/Corporate Planning and Strategy	9	17.3077	17.3077
Cyber Security/IT Infrastructure Solutions	7	13.4615	30.7692
Finance Management and Control/Standard Guidelines and Frameworks	6	11.5385	42.3077
E-Government Development and Regulation/Research and Development	14	26.9231	69.2308
Digital Economy Development/Digital Literacy and Capacity Development	16	30.7692	100
TOTAL	52	100	

Table 4 above shows the department of the respondents used in this study. Out of 52 respondents, 9 respondents representing 17.3077 percent of the population are from human resource and administration/corporate planning and strategy department. 7 or 13.4615 percent of the population, are from the cyber security/IT infrastructure solutions department. 6 representing 11.5385 percent of the population, are from the department of finance management and control/standard guidelines and frameworks. 14, representing 26.9231 percent of the population, are from e-government development and regulation/research and development department. 16 or 30.7692 percent of the population, are from the department of digital economy development/digital literacy and capacity development.

4.3 Analysis of Psychographic Data

Table 5: There is significant relationship between management information system (MIS) and enhancing e-governance interoperability.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Strongly agree	20	38.4615	38.4615
Agree	18	34.6154	73.0769
Disagree	8	15.3846	88.4615
Strongly disagree	6	11.5385	100
TOTAL	52	100	

Table 5 shows the responses of the respondents when there is a significant relationship between management information system and enhancing e-governance interoperability. Representing 20 respondents, 38.4615 percent strongly agreed that there is a significant relationship between management information system and enhancing e-governance interoperability. 18 respondents, representing 34.6154 percent, agreed that there is a significant relationship between management information system and enhancing e-governance interoperability. Representing 8 respondents, 15.3846 percent disagreed that there is a significant relationship between management information system and enhancing e-governance interoperability. 6 respondents, 11.5385 percent disagreed that there is a significant relationship between management information system and enhancing e-governance interoperability.

Table 6: There is no significant relationship between management information system (MIS) and e-governance goal.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT

Strongly agree	8	15.3846	15.3846
Agree	8	15.3846	30.7692
Disagree	20	38.4615	69.2307
Strongly disagree	16	30.7692	100
TOTAL	52	100	

Table 6 shows the responses of the respondents when there is no significant relationship between management information system and e-governance goal. Representing 8 respondents, 15.3846 percent strongly agreed that there is no significant relationship between management information system and e-governance goal. Representing 8 respondents, 15.3846 percent, agreed that there is no significant relationship between management information system and e-governance goal. Representing 20 respondents, 38.4615 percent disagreed that there is no significant relationship between management information system and e-governance goal. 16 respondents, 30.7692 percent disagreed that there is no significant relationship between management information system and e-governance goal.

Table 7: There is a significant relationship between e-learning and e-governance.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Strongly agree	13	25	25
Agree	22	42.3077	67.3077
Disagree	12	23.0769	90.3547
Strongly disagree	5	9.6154	100
TOTAL	52	100	

Table 7 shows the responses of the respondents when there is a significant relationship between e-learning and e-governance. Representing 13 respondents, 25 percent strongly agreed that there is a significant relationship between e-learning and e-governance. 22 respondents, representing 42.3077 percent, agreed that there is a significant relationship between e-learning and e-governance. Representing 12 respondents, 23.0769 percent disagreed that there is a significant relationship between e-learning and e-governance. 5 respondents, 9.6154 percent disagreed that there is a significant relationship between e-learning and e-governance.

Table 8: E-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Strongly agree	12	23.0769	23.0769
Agree	26	50	73.0769
Disagree	7	13.4615	86.5384
Strongly disagree	7	13.4615	100
TOTAL	52	100	

Table 8 shows the responses of the respondents if e-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed. Representing 12 respondents, 23.0769 percent strongly agreed that e-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed. 26 respondents, representing 50 percent, agreed that e-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not

properly managed. Representing 7 respondents, 13.4615 percent disagreed that e-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed. 7 respondents, 13.4615 percent disagreed that e-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed.

Table 9: Effective utilization of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Strongly agree	22	42.3077	42.3077
Agree	25	48.0769	90.3846
Disagree	3	5.7692	96.1538
Strongly disagree	2	3.8462	100
TOTAL	52	100	

Table 9 shows the responses of the respondents if an effective utilization of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization. Representing 22 respondents, 42.3077 percent strongly agreed that effective utilization of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization. 25 respondents, representing 48.0769 percent, agreed that effective utilization of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization. Representing 3

respondents, 5.7692 percent disagreed that Effective utilisation of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization. 2 respondents, 3.8462 percent disagreed that Effective utilisation of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization.

Table 10: Designing and implementing an effective e-government interoperability framework is a challenge to most government organizations.

	FREQUENCY	PERCENT	CUMULATIVE PERCENT
Strongly agree	16	30.7692	30.7692
Agree	20	38.4615	69.2307
Disagree	10	19.2308	88.4615
Strongly disagree	6	11.5385	100
TOTAL	52	100	

Table 10 shows the responses of the respondents if designing and implementing an effective e-government interoperability framework is a challenge to most government organizations. Representing 16 respondents, 30.7692 percent strongly agreed that designing and implementing an effective e-government interoperability framework is a challenge to most government organizations. 20 respondents, representing 38.4615 percent, agreed that designing and implementing an effective e-government interoperability framework is a challenge to most government organizations. Representing 10 respondents, 19.2308 percent disagreed that designing and implementing an effective e-government interoperability framework is a challenge to most government organizations. 6 respondents, 11.5385 percent disagreed that designing and

implementing an effective e-government interoperability framework is a challenge to most government organizations.

4.4 Test of Hypothesis

Hypothesis I

H_0: There is no significant relationship between Management Information Systems (MIS) and enhancing e-governance interoperability.

H_i: There is a significant relationship between Management Information Systems (MIS) and enhancing e-governance interoperability.

Level of Significance: 0.05

Critical Value: 7.81

Decision Rule: Reject the null hypothesis H_0 if the chi-square is equal to or greater than the critical value. Something else, acknowledge the null hypothesis.

Table 11: Test statistics

Test	There is significant relationship between management information system (MIS) and enhancing e-governance interoperability.
Chi-Square	11.3846
Df	3
Asymp. Sig	0.000

The expected cell frequency of 0 (.0%) is less than 5. The lowest expected cell frequency is 13.

Conclusions based on the decision rule: Since the chi-square = 11.3846 is greater than the critical value (7.81), we reject the null hypothesis and conclude that there is a significant relationship between management information system (MIS) and enhancing e-governance interoperability.

Hypothesis II

H_0: There is no significant relationship between Management Information Systems (MIS) and e-governance goal.

H_i: There is a significant relationship between Management Information Systems (MIS) and e-governance goal.

Level of Significance: 0.05

Critical Value: 7.81

Decision Rule: Reject the null hypothesis H_0 if the chi-square is equal to or greater than the critical value. Something else, acknowledge the null hypothesis.

Table 12: Test Statistics

Test	There is significant relationship between management information system (MIS) and e-governance goal.
Chi-Square	8.3077
Df	3
Asymp. Sig	0.000

The expected cell frequency of 0 (.0%) is less than 5. The lowest expected cell frequency is 13.

Conclusions based on the decision rule: Since the chi-square = 8.3077 is greater than the critical value (7.81), we reject the null hypothesis and conclude that there is a significant relationship between management information system (MIS) and e-governance goal.

Hypothesis III

H_0: There is no significant relationship between e-learning and e-governance.

H_i: There is a significant relationship between e-learning and e-governance.

Level of Significance: 0.05

Critical Value: 7.81

Decision Rule: Reject the null hypothesis H_0 if the chi-square is equal to or greater than the critical value. Something else, acknowledge the null hypothesis.

Table 13: Test Statistics

Test	There is significant relationship between e-learning and e-governance.
Chi-Square	11.2308
Df	3
Asymp. Sig	0.000

The expected cell frequency of 0 (.0%) is less than 5. The lowest expected cell frequency is 13.

Conclusions based on the decision rule: Since the chi-square = 11.2308 is greater than the critical value (7.81), we reject the null hypothesis and conclude that there is a significant relationship between e-learning and e-governance.

CHAPTER FIVE

SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Summary of Findings

The purpose of this study the purpose of this study is to assess and understand how e-governance interoperability can be enhanced through e-learning and management information system in an organization. The hypotheses were meant to know if there is significant relationship between management information system and enhancing e-governance interoperability. In addition, the study seeks to find out whether there is a significant relationship between management information system (MIS) and e-governance goal. Finally, the study tries to find out that there is a significant relationship between e-learning and e-governance.

The analyses of the collected data revealed the increase of interoperability of e-governance with e-learning and management information systems in an organization, whose objectives were;

1. To examine the issues associated with E-governance systems interoperability.
2. To determine how e-governance interoperability can be enhanced by management information systems (MIS).
3. To find out if e-learning will improve people's participation in e-governance systems.

5.2 Conclusion

The results of the relevant literature review and data analysis show that e-learning and management information systems are important for improving e-governance interoperability, and they are greatly helpful in organizational collaboration and contribute to bringing an integrated information flow within the organization. In an organization, management information system transforms

physical and manual processes into intranets and departmental integrated systems. A functioning e-learning and management information system requires resources such as ICT infrastructure, skills and human resources to improve interoperability of government systems and initiatives to make governments more open to citizen engagement and participation for a better governance. With the help of management information system, governments can easily produce, analyze, disseminate and process information across ministries and department. In addition, e-learning has the potential to meet the growing challenges by enhancing the possible way to provide adequate experience and knowledge to citizens and employees.

5.3 Recommendation

On the premise of the above discussion, we make the subsequent recommendations:

1. Governments should implement management information systems to each and every department of its initiatives on automation because anyone in the initiatives could use information to make timely decision on that information at different level.
2. E-learning and Management information systems should be seen as a vital resource of e-government interoperability.
3. Governments should use e-learning and management information systems to eliminate the communication gap between government initiatives as well as citizens.

5.4 Research Contribution

This thesis had a practical impact by highlighting the importance of communication technology for management information systems and e-learning. It enables an integrated e-government system that connects citizens and other public administration stakeholders.

5.5 Future Research Directions

Interoperability was studied from the perspective of e-learning and management information systems. Furthermore, this study was based on one case of a government organization, so future research can be done on other organizations to gain more insights from general knowledge about other developing countries such as Nigeria.

APPENDIX I

QUESTIONNAIRE

INSTRUCTION: Please endeavor to fill out the questionnaire by ticking the appropriate answer (s) from the choices or providing the necessary information when required.

SECTION A

DEMOGRAPHIC DATA

1. Gender
   a. Male ☐
   b. Female ☐
2. Professional / work experience
   a. 1-5 years ☐
   b. 6-10 years ☐
   c. 11-15 years ☐
   d. 16-20 years ☐
   e. Above 20 years ☐
3. Educational qualification
   a. SSCE/NECO/WAEC ☐
   b. NCE/OND ☐
   c. HND/BSC ☐
   d. PGD/MSc ☐
   e. PhD ☐
4. Department

a. HRA/CPS Department ☐

b. CS/ITIS Department ☐

c. FMC/SGF Department ☐

d. EGDR/R&D Department ☐

e. DED/DLCD Department ☐

SECTION B

QUESTIONS ON ENHANCING E-GOVERNANCE INTEROPERABILITY IN THE CONTEXT OF E-LEARNING AND MANAGEMENT INFORMATION SYSTEM

5. There is significant relationship between management information system (MIS) and enhancing e-governance interoperability.

   a. Strongly agreed ☐

   b. Agreed ☐

   c. Disagreed ☐

   d. Strongly disagreed ☐

6. There is no significant relationship between management information system (MIS) and e-governance goal.

   a. Strongly agreed ☐

   b. Agreed ☐

   c. Disagreed ☐

   d. Strongly disagreed ☐

7. There is a significant relationship between e-learning and e-governance.

   a. Strongly agreed ☐

b. Agreed ☐

c. Disagreed ☐

d. Strongly disagreed ☐

8. E-learning is a necessity to provide adequate experience and knowledge which could adversely affect the professional development in the work force if not properly managed.

a. Strongly agreed ☐

b. Agreed ☐

c. Disagreed ☐

d. Strongly disagreed ☐

9. Effective utilization of management information system (MIS) can seamlessly enhance information sharing, communication and integration amongst the departments in the organization.

a. Strongly agreed ☐

b. Agreed ☐

c. Disagreed ☐

d. Strongly disagreed ☐

10. Designing and implementing an effective e-government interoperability framework is a challenge to most government organizations.

a. Strongly agreed ☐

b. Agreed ☐

c. Disagreed ☐

d. Strongly disagreed ☐

DATA INTEGRITY IN CYBER SUPPLY CHAIN SECURITY FOR CUSTOMS OPERATIONS, VULNERABILITIES AND SOLUTIONS

DECLARATION

I hereby declare that all information in this document has been obtained and presented by academic rules and ethical conduct. I also declare that, as required by these rules and conduct, I had fully cited and referenced all material and results that are not original to this work.

Name, Last name: Mustapha Nuhu

Signature:

Date:

CERTIFICATION/ APPROVAL

This is to certify that this project "**DATA INTEGRITY IN CYBER SUPPLY CHAIN SECURITY FOR CUSTOMS OPERATIONS, VULNERABILITIES AND SOLUTIONS**" was carried out by **MUSTAPHA MOHAMMAD NUHU** with Matriculation Number **ACE22120019** in accordance with the rules and regulations governing the preparation and presentation of research project in National Open University of Nigeria and in partial fulfilment of the Master of Science in Cyber Security, and it is hereby approved for its contribution to knowledge.

Dr. Joseph Adebayo OJENIYI	Date
Project Supervisor 2	Date
Program Coordinator	Date
External Examiner	Date

DEDICATION

To my parents: Thanks for supporting me through this cyber maze, even when I couldn't explain what I was doing. You're the real MVPs!

ACKNOWLEDGEMENT

First and always, I would thank Allah for giving me the strength to finish this work.

I owe immense thanks to my supervisor, Dr. Joseph Adebayo OJENIYI An Associate Professor of Cyber Security Science, Department of Cyber Security Science, School of Information and Communication Technology of Federal University of Technology Minna and Prof. Ismaila Idris of Department of Cyber Security Science, School of Information and Communication Technology of Federal University of Technology Minna for their guidance and patience, even when my ideas seemed to wander off into the cyber wilderness.

Big shoutout to the **National Open University of Nigeria (NOUN)** for providing a cozy den for my research antics.

To the brave participants who willingly embarked on this data adventure with me, your courage is commendable and your insights invaluable.

And to my family, who patiently endured my endless rants about cyber supply chains and data integrity, your unwavering support deserves its own Nobel Prize in Patience.

In conclusion, I acknowledge with gratitude all those who have played a part, however small, in the completion of this research project. Your contributions have been invaluable, and I am truly grateful for your support.

APPENDICES

Appendix A: Questionnaire

1. Position/Role: a. ICT Specialist b. Customs Officer c. Customs Technical Support company d. Customs Agent e. Other (please specify): _____	2. Years of working Experience: a. Less than 1 year b. 1-5 years c. 6-10 years d. More than 10 years Other:
3. Type of Customs Operations: a. Import b. Export c. ICT Related d. Other:	**Objective 1: Identify Key Vulnerabilities** 4. On a scale from 1 to 5, where 1 indicates "Not a Concern" and 5 indicates "Highly Concerning," how do you rate your perception of the vulnerability of data integrity in the cyber supply chain within customs operations? Not a Concern 1 2 3 4 5 Highly Concerning
5. What do you believe are the most critical vulnerabilities that could compromise data integrity in the cyber supply chain for customs operations? (Check all that apply) a. Insufficient Encryption Protocols: b. Inadequate Authentication Measures: c. Lack of Regular Cybersecurity Training: d. Limited Collaboration with External Cybersecurity Experts: e. Outdated Software and Systems: f. Inadequate Monitoring and Detection Systems: g. Insufficient Physical Security Measures: h. Incomplete Data Back-Up Protocols: i. Vendor and Third-Party Risks: j. Inadequate Incident Response Planning: k. Other:	**Objective 2: Analyze Impacts of Data Integrity Breaches** 6. Have you or your organization experienced any data integrity breaches in the cyber supply chain for customs operations? ☐ Yes ☐ No Not Sure
7. If yes, please describe the impacts of the data integrity breaches on your organizational operations. _____	8. Please select the most applicable adverse impacts of data integrity breaches on customs operations and the broader supply chain: (Check all that apply) a. Trade disruptions and delays b. Financial losses and incorrect duty calculations c. Compromised national security and increased security risks d. Erosion of public trust in customs operations e. Increased smuggling, fraud, and illegal movement of goods f. Operational inefficiencies and manual checks g. Reputational damage and credibility issues h. Legal consequences and potential fines i. Risks to intellectual property and proprietary information j. Impact on supply chain partners and strained relationships k. Regulatory non-compliance and oversight actions Increased costs for cybersecurity measures and investigations
Objective 3: Explore Cybersecurity Measures and Protocols 9. How confident are you in the effectiveness of the current cybersecurity measures and protocols in place for safeguarding data integrity in customs operations? Very Confident 1 2 3 4 5 Not Confident at All	10. Please list the cybersecurity measures and protocols currently employed in your organization to maintain data integrity. (Check all that apply) a. Encryption b. Access Controls c. Multi-Factor Authentication (MFA) d. Firewalls e. Intrusion Detection and Prevention Systems (IDPS)

	f. Regular Security Audits and Assessments g. Security Information and Event Management (SIEM) h. Data Backups i. Patch Management j. Incident Response Plan k. Employee Training and Awareness l. Vendor Security Assessment m. Network Segmentation n. Endpoint Security o. Regular Policy Review p. Other:
11. Which of the following cybersecurity measures do you think is most effective in ensuring data integrity in the cyber supply chain for customs operations? a. Encryption Protocols b. Regular Cybersecurity Training for Staff c. Collaboration with External Cybersecurity Experts d. User Authentication Processes e. Software and Systems Updates f. Physical Security Measures g. Data Back-Up Protocols h. Incident Response Planning i. Other:	**Objective 4: Propose Solutions for Data Integrity Enhancement** 12. On a scale from 1 to 5, where 1 indicates "Not Feasible" and 5 indicates "Highly Feasible," how would you rate the feasibility of implementing technological solutions for data integrity enhancement in customs operations? Not Feasible 1 2 3 4 5 Highly Feasible
13. In your opinion, what comprehensive solutions do you believe would be effective in enhancing data integrity in the cyber supply chain for customs operations? (Check all that apply) a. Implementation of Blockchain Technology b. Enhanced Encryption Protocols c. Regular Cybersecurity Training for Staff d. Effective Access control Implementation e. Collaboration with External Cybersecurity Experts f. Adoption of Advanced Monitoring and Detection Systems g. Robust Incident Response Planning h. Integration of Physical Security Measures i. Implementation of Vendor and Third-Party Security Assessments j. Regular Software and Systems Updates k. Establishment of Cross-Border Information Sharing Frameworks l. Other:	14. Please rank the following potential solutions for enhancing data integrity in the cyber supply chain for customs operations based on your preference: a. Implementation of Blockchain Technology b. Enhanced Encryption Protocols c. Regular Cybersecurity Training for Staff d. Collaboration with External Cybersecurity Experts e. Adoption of Advanced Monitoring and Detection Systems f. Robust Incident Response Planning g. Integration of Physical Security Measures h. Implementation of Vendor and Third-Party Security Assessments i. Regular Software and Systems Updates j. Establishment of Cross-Border Information Sharing Frameworks k. Implementation of Blockchain Technology l. Enhanced Encryption Protocols m. Regular Cybersecurity Training for Staff n. Collaboration with External Cybersecurity Experts o. Adoption of Advanced Monitoring and Detection Systems p. Robust Incident Response Planning q. Integration of Physical Security Measures r. Implementation of Vendor and Third-Party Security Assessments s. Regular Software and Systems Updates t. Establishment of Cross-Border Information Sharing Frameworks
15. To what extent do you believe that international collaboration and information sharing can contribute to enhancing data integrity in the cyber supply chain for customs operations? Not at All 1 2 3 4 5 Extremely	

ABSTRACT

This research investigates the critical domain of "Data Integrity in Cyber Supply Chain Security for Customs Operations, Vulnerabilities, and Solutions." Employing a comprehensive questionnaire, responses were gathered from 108 participants representing diverse roles within customs operations. The study provides a nuanced exploration of data integrity vulnerabilities within customs operations, offering key insights into the multifaceted challenges faced by stakeholders in securing the cyber supply chain. The research delves into the impacts of data integrity breaches, drawing from real-world experiences reported by 37 respondents who have encountered such incidents. The findings reveal a spectrum of consequences, ranging from financial losses and trade disruptions to compromised national security and erosion of public trust. This exploration contributes valuable knowledge to inform strategic responses and mitigation efforts in customs organizations. Assessment of current cybersecurity measures and protocols in customs operations forms a crucial aspect of the study. Participants' confidence levels in the effectiveness of these measures are analyzed, providing a practical reference for organizations looking to enhance their cybersecurity posture. The research identifies preferred cybersecurity strategies, including encryption protocols, access controls, multi-factor authentication, and other measures, offering actionable insights for organizations seeking to fortify their defenses. Furthermore, the study proposes feasible solutions for enhancing data integrity within customs operations. By evaluating the feasibility of implementing technological solutions and ranking preferences for enhancement measures, the research provides practical guidance for strategic planning. Emphasizing solutions such as regular cybersecurity training, advanced monitoring systems, and collaboration with external experts, the study contributes valuable recommendations for customs organizations aiming to bolster their cybersecurity resilience. In summary, this research makes a substantial contribution to the understanding of data integrity challenges within the cyber supply chain of customs operations. It bridges existing knowledge gaps by providing practical insights into vulnerabilities, impacts of breaches, current cybersecurity measures, and feasible enhancement solutions. The findings have implications for customs organizations, policymakers, and cybersecurity practitioners, guiding effective strategies in the dynamic landscape of cyber threats.

Keywords: Customs Operations, Data Integrity, Cyber Supply Chain Security, Vulnerabilities, Cybersecurity Solutions.

CHAPTER ONE

INTRODUCTION

1.0 BACKGROUND OF THE STUDY

Data integrity within the customs supply chain constitutes a critical component of its security measures, emphasizing the management of essential data integrity, encompassing information technology systems, software, and networks. Customs Supply chain management faces significant risks from threats such as cyber terrorism, malware, and data theft. Customs operations are critical in safeguarding the security and efficiency of international trade in an era of increased globalization and digitization. The complicated and linked nature of global supply chains, on the other hand, exposes vulnerabilities that could jeopardize the integrity of data within customs processes.

Today, supply chain is becoming more complex and global. It is now increasingly dependent on information technology to increase its efficiency and to support communication and coordination between network suppliers, manufacturers, distributors, and even transportation service providers. Simultaneously, if information technology is not appropriately secured, it will increase supply chain vulnerability to cyber-attacks (Kirk, 2014). In this context, a supply chain is regarded as a series of strong interrelated links. Accordingly, the necessity to coordinate several business partners, business processes and diverse actors across the supply chain (Du Toit & Vlok, 2014) gave rise to the field of Supply Chain Process Design (SCPD) (Simchi-Levi et al., 2000). At the core of gaining a competitive advantage through SCPD is supply chain integration; when process integration is achieved, the supply chain operates as a single entity (Farhoomand & Farhoomand, 2005).

In the context of customs supply chains, data integrity is a core concern due to the large number of actors involved, the complexity of their structural links, and the critical nature of interactions between these actors. Data integrity ensures the accuracy, reliability, and security of information as it flows through this intricate network, safeguarding against unauthorized alterations and data breaches that could disrupt the smooth operation of the customs supply chain. In fact, the theoretical and practical understanding of the concept of a customs supply chain is still marked by ambiguities (Ibourk et al., 2018).

Furthermore, supply chain management needs to be carefully planned to get the right product, in the right quantity, and in the right place at the right time to reach the customers, and necessarily at the right price as claimed by (Mangan & Lalwani, 2016).

The supply chain is crucial in the movement of commodities across borders in an increasingly integrated global economy. The cyber supply chain has grown equally important with the growth of digital technology and information systems. However, digitization presents new vulnerabilities and threats, potentially jeopardizing customs data integrity.

The purpose of this thesis is to thoroughly explore the vulnerabilities that endanger data integrity in the cyber supply chain for customs operations and to suggest appropriate solutions to prevent these risks.

2.0 STATEMENT OF THE PROBLEM

The modernization and digital transformation of customs operations have resulted in a network of interconnected systems and data flows throughout the supply chain. This network is vulnerable to a number of cyber threats that might jeopardize the integrity of important data, disrupt cross-border trade, and potentially have far-reaching economic and security consequences. There have been a lot of cyber-attacks and compromises to the Cyber Supply-Chain in recent times, some examples are the SolarWinds incident which significantly affected the Supply-Chain (SC) of 18000 customers Information Technology (IT) systems which included large organizations such as Microsoft and U.S. department of Justice (Lakshmanan, 2021; Dustin Volz, 2021). Additionally, (Shivajee et al., 2019) explained that the application of effective information technology tools ensures the organization's continued growth. Prominently, it regulates a set of techniques used to increase the security and integrity of a programme, network, and data from unauthorized and harmful access. Likewise, it refers to the process and technological body (P.S et al., 2018). Despite the crucial importance of customs operations and the supply chain in this setting, there is a gap in knowing the full range of associated vulnerabilities that can threaten data integrity and its subsequent solution.

3.0 RESEARCH QUESTIONS

- What are the key vulnerabilities that can compromise data integrity in the cyber supply chain within customs operations?
- What are the potential impacts of data integrity breaches on customs operations and cross-border trade?
- What existing cybersecurity measures and protocols are currently in place in customs operations, and how effective are they in safeguarding data integrity?
- What comprehensive and feasible solutions can be proposed to enhance data integrity in the cyber supply chain for customs operations?

4.0 AIM OF THE STUDY

The aim of this thesis is to thoroughly explore the vulnerabilities and threats to data integrity within the cyber supply chain in the context of customs operations. The research seeks to provide effective solutions and tactics that improve data integrity, thereby boosting the security and reliability of customs procedures in the ever-changing global trade context.

5.0 SPECIFIC OBJECTIVES

The primary objectives of this research are as follows:

1. To identify the key vulnerabilities that can compromise data integrity in the cyber supply chain within customs operations.
2. To analyses the potential impacts of data integrity breaches on customs operations and cross-border trade.
3. To explore existing cybersecurity measures and protocols in customs operations and evaluate their effectiveness in safeguarding data integrity.
4. To propose comprehensive and feasible solutions to enhance data integrity in the cyber supply chain for customs operations.

6.0 MOTIVATION

The motivation for this study derives from the growing relevance of customs operations in facilitating international trade and protecting national security. As supply chains grow increasingly digital, they become vulnerable to a variety of cyber threats that can disrupt operations, compromise data, and have a global impact on economies. Recent high-profile cyber-attacks on supply chain components, such as the SolarWinds incident, have highlighted the importance of strengthening cybersecurity safeguards across the whole supply chain, including customs operations. Furthermore, the research is motivated by the lack of comprehensive studies focusing on data integrity within the context of customs operations and the cyber supply chain. While cybersecurity discussions often focus on network protection and data confidentiality, the aspect of data integrity is equally critical. Unauthorized modifications or alterations of data within customs operations can lead to inaccurate assessments, regulatory violations, delayed shipments, and economic losses. Thus, understanding the vulnerabilities specific to data integrity and proposing effective solutions is imperative for maintaining the efficiency and security of global trade networks.

7.0 SCOPE OF THE STUDY

This research delves into data integrity within the cyber supply chain, focusing specifically on customs operations. While the study draws on global customs practices and supply chain dynamics, it centers on the Nigerian Customs Service to provide a geographical scope. This localized approach allows for a detailed examination of vulnerabilities, impacts, and solutions pertinent to Nigeria's unique customs environment.

Methodologically, the research employs a survey-based approach with the following scopes:

- Population Scope: The study targets customs officials, IT security experts, and supply chain professionals within Nigeria.
- Instrument Scope: Data collection relies on structured questionnaires designed to elicit specific information about data integrity challenges and cybersecurity practices.
- Data Collection Scope: Surveys will be distributed electronically across various customs departments and related entities within Nigeria.
- Analysis Scope: Responses will be analyzed using statistical methods to identify patterns, correlations, and insights specific to the Nigerian context.

The research aims to contribute to the body of knowledge on cyber supply chain security by providing a comprehensive analysis of the Nigerian Customs Service's data integrity measures. It will not reiterate the general objectives previously stated but will build upon the comparative analysis with similar studies conducted in Sweden, offering a focused examination of the Nigerian scenario.

8.0 SIGNIFICANCE OF THE STUDY

This research is critical for various types of stakeholders, including Nigeria customs administrations, supply chain players, and the broader cybersecurity community. The research contributes to improving the cybersecurity measures required for safeguarding customs operations by identifying vulnerabilities and suggesting solutions that are suitable. This is critical not only for securing sensitive data and facilitating trade but also for ensuring national security by enhancing border monitoring and regulation. The study's international implications will enhance global trade by improving trust and reducing trade barriers, while its findings aid in developing policies and serve as a platform for future research in cybersecurity, supply chain management, and customs operations. Furthermore, the study enhances public awareness about the supply chain's cybersecurity challenges, thereby improving practices and vigilance in this critical industry.

9.0 ORGANIZATION OF THE THESIS

The thesis is structured as follows; Chapter 1 presents the introductory section of this research. Chapter 2 discusses the literature in the domain of data integrity in supply chain security and highlights the research's contribution to the same. Chapter 3 presents the research methodologies used in this research. Chapter 4 presents results and discussion which was where the conceptual framework was also discussed. Chapter 5 presents summary, some concluding remarks and recommendations for the thesis.

CHAPTER TWO

LITERATURE REVIEW

2.0 Preamble

This section helps to build the foundation of the conceptual framework. Numerous research reports, policies, strategies, and related documentation emphasize the importance of incorporating data integrity into the operational objectives of customs capacity building projects. One example is the Declaration of the Customs Co-operation Council Concerning Good Governance and Integrity in Customs (WCO Revised Arusha Declaration), which lays down the key principles a customs administration should apply when launching a comprehensive integrity development program (WCO, 2003).

The global landscape of trade and commerce is increasingly reliant on sophisticated supply chain systems, driven by digital technologies and the seamless flow of information. Customs operations play a pivotal role in regulating and facilitating the movement of goods across borders, ensuring compliance with various regulations, and protecting national interests. Supply chain managers and suppliers share a large amount of data to support communication and collaborative efforts as well as build trust in the supply chain management process (Urciuoli & Hintsa, 2017).

As supply chains become more digitally connected and data-driven, they are also exposed to a growing array of cyber threats. Among the paramount concerns within this evolving paradigm is the assurance of data integrity. As we embark on this exploration, it is essential to recognize the dynamic nature of the customs and supply chain environment, where emerging technologies continually reshape the landscape and new threat vectors emerge. Due to the lack of significant academic research on data security and the fast changing dynamics in the field, information security and data security seminal conceptual and theorical literature in the field is still emerging and being developed (Burkhead, 2014; Djatsa, 2019; Okonofua, 2018).

This literature review endeavors to synthesize existing knowledge and research findings related to data integrity within the customs and supply chain domain, shedding light on the current state of the field and highlighting areas that warrant further investigation. Ultimately, it aims to contribute to the development of a comprehensive framework for enhancing data integrity in cyber supply chain security for customs operations and, in doing so, safeguarding the global trade ecosystem.

2.1 Data Integrity and Information Security Concepts

Data, cyber, and information security are broad topics that have applications in supply chain and logistics management. Organizational assets are often the target of attackers attempting to steal data or information (Burkhead, 2014; Djatsa, 2019; Okonofua, 2018). An asset can be a database, employee information, organizational intellectual property, technology system or application, or any other form of valuable digital information (Burkhead, 2014; Djatsa, 2019; Okonofua, 2018). All of these assets can be targeted and should be protected from attack as part of a comprehensive organizational security strategy (Burkhead, 2014; Djatsa, 2019; Okonofua, 2018) For supply chain and logistics organizations assets could be client lists, customer payment information, or even business operation protocols.

2.2 Cyber Supply Chain Security

According to (Gavin & Sarah, 2021) Cyber Supply chain security is the part of supply chain management that focuses on the risk management of external suppliers, vendors, logistics and transportation. Its goal is to identify, analyze and mitigate the risks inherent in working with other organizations as part of a supply chain. Supply chain security involves both physical securities relating to products and cybersecurity for software and services.

Due to the interdisciplinary nature of Cyber Supply Chain Security (CSCS), different industries have started to work in CSCS. Due to this, multiple coined terms have been made for essentially the same thing. (Bartol, 2014).

According to (Bartol, 2014) the following list are all essentially interchangeable:

- Information and Communications Technology Supply-Chain Risk Management (ICT SCRM)
- Information and Communications Technology Supply-Chain Security (ICT SCS)
- Supply-Chain Risk Management (SCRM)
- Cyber Supply-Chain (CSC)
- Cyber Supply-Chain Security (CSCS)
- Cyber Supply-Chain Risk Management (CSCRM)

Supply chain security should be a high priority for organizations, as a breach within the system could damage or disrupt operations. Vulnerabilities within a supply chain could lead to unnecessary costs, inefficient delivery schedules and a loss of intellectual property. Additionally, delivering products that have been tampered with or are unauthorized could be harmful to customers and lead to unwanted lawsuits (Gavin & Sarah, 2021).

Security management systems can help protect supply chains from physical and cyber threats. While threats cannot be completely erased, supply chain security can work towards a more secure, efficient movement of goods that can recover rapidly from disruptions (Gavin & Sarah, 2021).

2.3 Threats, Challenges, and Vulnerabilities in the Cyber Supply-Chain

(Kim & Im, 2014) found several CSC challenges which are: CSC management including complete integration of CSC modules and continued improvement, responsibility management and integration of CSCS both technical and human resources, general information security and Cyber Sec challenges. (Kim & Im, 2014) presented two future challenges to CSCS is to take advantage of new technologies and as the CSC moves down the SC to primary, secondary, and tertiary vendors security measures must be in place.

(Lu et al., 2017) and (Zage et al., 2013) said it is difficult to protect and maintain a CSC, as this spans over goods, factories, partners, fright, people, and information on numerous suppliers across multiple tires. However, (Windelberg, 2016) wrote that organizations typically only have visibility up- and downstream of one to two tiers and the complex and dynamic nature of the SC can make assessing risk and protecting the CSC difficult.

According to (Lu et al., 2017), (Pandey et al., 2020), (Wang & Franke, 2020), (Ghadge et al., 2019), (Zage et al., 2013) a breach or disruption at any point or node in the SC can affect the entire global CSC. Thus, the CSC is only as secure as the weakest link. (Wang & Franke, 2020) gave an example of where a business bought payment processing from a third-party whose services goes down. Now the business cannot process payments and concludes that any third-party services the business relies on whose services could go down could cause business interruptions. (Wang & Franke, 2020).

2.4 Current Frameworks, Models, and Approaches in Supply Chain Security

Various frameworks, models, and methods exist for enhancing supply chain security. These approaches are designed to address the challenges and vulnerabilities in the supply chain and ensure the integrity, confidentiality, and availability of goods and information.

(Hou et al., 2019) developed a framework that takes into consideration the number of suppliers and their tiers for addressing security requirements in the supply chain. They also found that none of the existing frameworks and methods for securing information control systems have taken into consideration cyber supply chain security (Hou et al., 2019). (Annarelli et al., 2020) discussed the concept of a cyber resilient system, where a system is cyber resilient if it has two

main features (1) robustness against potential predictable attacks, and (2) the ability to come back to a safe state without compromised system behavior and functionality when a successful attack has happened.

(Yeboah-Ofori et al., 2019) presented the concept of Cyber Threat Intelligence which is a proactive measure. They wrote that without Cyber Threat Intelligence it would be very difficult to effectively mitigate attacks, risk, and vulnerabilities against the CSC.

(Roy et al., 2012) broke down the SCS into hard and soft security. Where hard security is about physical theft, damage to supply and so on, and soft security is about data security, technology, and management. This soft security included the flow of information, information sharing, IT systems, human error and risk, and third-parties and vendors. (Roy et al., 2012) (Ghadge et al., 2019) classified points of penetration to the CSC as technical, human, and physical. (Lu et al., 2017) categorized the SCS practice in four classes, detection, prevention, response, and mitigation. Also stated that they believed prevention was the most important class.

According to (Boyes, 2015) and (Sawik, 2022) with these complex and sophisticated CPS in the SC the traditional Confidentiality, Integrity, and Availability (CIA)-triad is not enough, and a better suited method would be the Parkerian hexad. The authors continued to state that the objective of CyberSec is to protect the six areas in the Parkerian hexad. The Parkerian hexad consists of the CIA-triad and includes the addition of utility, authenticity, and possession. (Boyes, 2015) points out that Parkerian hexad does not include trustworthiness. Thus, (Boyes, 2015) suggested the Parkerian hexad should be augmented with safety and resilience to encompass trustworthiness. (Windelberg, 2016) listed the five objectives in Supply-Chain Risk Management (SCRM) as, security, reliability, safety, quality, and trustworthiness.

2.5 Public and Private Standards and Frameworks for Cyber Supply-Chain Security

(Bartol, 2014) argued that public, private, and academic stakeholders need to come together to help secure and maintain a good CSCS. (Ghadge et al., 2019) stated that the lack of accepted unified standards and guidelines for cyber defense to the CSC was hindering the development of a good cyber defense. (Bartol, 2014) continued that there are a number of standards for CSCS, however most of them originate from the National Defense Industrial Association (NDIA) Guidebook. (Bartol, 2014) explained that you can see an influence of the NDIA Guidebook in the following standards International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) 27036, National Institute of Standards and Technology (NIST) SP 800-53, and NIST Interagency Report (NISTIR) 7622.

2.5.1 NDIA Guidebook

(NDIA, 2008) discussed the vulnerabilities of SC and that no system was free of all vulnerabilities and that failure to a system may have greater consequences than just system functionality. (NDIA, 2008) presented the following vulnerabilities related to SCS: information sharing (sharing confidential information may lead to counterfeiters), change of supplier in the SC could introduce new vulnerabilities, and intentional undocumented addition to the product during development like insertion of Trojans, malware, and viruses.

2.5.2 ISO/IEC 27036

(ISO/IEC, 2022) stated that a large significant of organizations had relationships with other vendors. Thus, most of these suppliers needed some information or access to the information system to provide their service. This introduced an information security risk to all members in the SC. All members both supplier and acquirer needed to take equal responsibility to uphold good information security, while also having to trust that the other party upholds their information security. Examples of these risks are software vulnerabilities and intentional or unintentional release of sensitive information. When acquiring a product or services it could be difficult to enforce your information security requirements on tier two and three suppliers as visibility upstream is limited. (ISO/IEC, 2022) presented some vulnerabilities and inherent information security risk when working with suppliers: weakness in governance which may lead to loss of information, or supplier outsourcing part of the service thus reduction in control for the acquirer, miscommunication and misunderstanding in the supplier relationship, and geographical, social and cultural differences between supplier and acquirer. (ISO/IEC, 2022) continued with specific examples of information security risk in the SC as: software or services with pre-existing vulnerabilities introduced in the SC; poor quality of product and services; counterfeited products or services; physical access to onsite systems; access, processing, and storage of information by supplier; and use of application and services not controlled and monitored by acquires of their information on the supplier's systems. (ISO/IEC, 2022) specified how the life cycle of a supplier should be managed, including, planning, selection, agreement, management, and termination of a supplier relationship.

2.6 Customs Supply Chain Concept

Recent years have witnessed a notable upswing in scholarly attention towards supply chains, with an increasing focus on refining the concept and metrics of supply chains across diverse industries, ranging from retail, import-export, and healthcare to customs logistics (Elms & Low, 2013). While numerous scholars have proposed definitions for the term 'customs supply

chain,' many of these definitions lack specificity. Consequently, this study offers a structured definition of a customs supply chain for clarity and precision.

“Customs supply chain is a set of all aspects that incorporate the moving of cargo and information from the exporter through the transport process, the logistics operations, customs crossing and financial process to the final importer. The customs supply chain is no longer contained within a country’s borders, but encompasses all nations, whether they are exporters, importers or manufacturers. (Hammadi et al., 2015)”

As a result, our supply chain structure is composed of five blocks. That is the proposed building blocks of our definition come from the existing operations management within supply chain, emphasizing on customs operations: (Lamia et al., n.d.)

- **Customs operators:** the parties that receive and send the goods: an importer in the receiving country and an exporter from the sending country. Importation and exportation are the main financial transactions of international trade.
- **Transport process:** multimodal transport, which covers at least two modes of transport, with the main one being sea transport (CTBL: combined transportation bill of lading).
- **Customs crossing:** includes any point authorized by the customs authorities for the crossing of external borders. It covers declaration processing, custom clearance, data analysis, risk assessment, document checking, scanning, physical inspection, etc. Accordingly, customs crossing is the main bloc for securing the supply chain, due to customs intervention in all stages along the routing of cargo. It includes the border checks both for goods entering and exiting the country.
- **Logistics operations:** encompasses of all activities associated with the flow and transportation of goods, as well as the associated information. Such activities follow three steps: ‘organize’ (organize the activities for each function of the supply chain to deliver results); ‘carry out’ (implementing and controlling what was planned); and ‘monitor’ (which denotes checks and measurement of the functions and results against Customs’ policies, objectives and requirements). It comprises activities such as warehousing, inventory, materials, order fulfillment, supply/demand planning, and management of third-party logistics service providers.
- **Financial process:** supports financial transactions between the actors in the supply chain and facilitates the monetary flows.

2.6.1 Stakeholders in Customs Supply Chain

A customs supply chain is a complex network (Christopher, 2016). Based on their roles and responsibilities in the customs supply chain, stakeholders are grouped into categories related to managing their processes and activities and achieving their goals and objectives. These stakeholders are broadly grouped into five different categories, as listed in Table 1.

Category	Stakeholders
Commercial category	Importer, exporter
Organizing category	Forwarder; shipping line agent; logistics service provider
Physical category	Sea terminal operator; shipping line/sea carrier; pre- or on-carrier: air/rail/sea carriers; border highway carriers; logistics service provider; empty container depot operator
Authorizing category	Customs; port authorities; seaport police; river police; inspection authorities
Financial category	Bank; insurance company

Table 1: Stakeholders of customs supply chain

The commercial category is concerned with the importation and exportation and constitutes the commercial transactions (buying/selling). This category has competencies and direct interests in providing products to end-customers from a foreign country into a domestic country—import, or in the opposite direction, export. For transporting the products, logistics services provided by the second and third categories are employed. The organizing category mainly consists of brokers and intermediaries who integrate the cargo transportation, whereas the physical category performs the physical flows. These two categories usually have less interest in products but focus on the operational efficiency of the physical flow of cargo.

The authorizing category has the responsibility for monitoring and inspecting the cargo flow for the purpose of enforcing security and regulatory requirements and international standards. Lastly, the financial category supports financial transactions between the actors in the supply chain and facilitates the monetary flows. These five categories depend on one another to achieve the goals of the customs supply chain. These dependencies influence the configuration of a customs supply chain network and affect the many operational, tactical and strategic level decisions of the chain.

2.7 Summary/meta-analysis of Reviewed of Related Works

The reviewed literature provides a comprehensive overview of the critical aspects related to data integrity in cyber supply chain security for customs operations. The following key points summarize the literature:

Citation	Title	Explanation
(WCO, 2003)	Importance of Data Integrity in Customs Operations	Emphasizes the significance of incorporating data integrity into customs capacity building projects, as outlined in the WCO Revised Arusha Declaration (WCO, 2003).
(Urciuoli & Hintsa, 2017)	Digital Transformation and Cyber Threats in Supply Chains	Highlights the increasing reliance on sophisticated supply chain systems driven by digital technologies and the pivotal role of customs operations (Urciuoli & Hintsa, 2017).
(Burkhead, 2014; Djatsa, 2019; Okonofua, 2018)	Challenges and Vulnerabilities in Cyber Supply Chain Security	Discusses challenges and vulnerabilities in Cyber Supply Chain Security (CSCS), including management integration and information security challenges (Burkhead, 2014; Djatsa, 2019; Okonofua, 2018).
(Annarelli et al., 2020; Boyes, 2015; Hou et al., 2019; Roy et al., 2012; Sawik, 2022; Windelberg, 2016; Yeboah-Ofori et al., 2019)	Frameworks and Approaches for Supply Chain Security	Reviews existing frameworks, models, and methods for enhancing supply chain security (Hou et al., 2019; Annarelli et al., 2020; Yeboah-Ofori et al., 2019; Roy et al., 2012; Boyes, 2015; Sawik, 2022; Windelberg, 2016).
(Bartol, 2014; Gavin & Sarah, 2021)	Diverse Terminology in Cyber Supply Chain Security	Acknowledges the diverse terminology in Cyber Supply Chain Security (CSCS) and lists interchangeable terms. Emphasizes the need for standardization (Bartol, 2014; Gavin & Sarah, 2021).

(Elms & Low, 2013; Lamia et al., n.d.)	Stakeholders and Components in Customs Supply Chain	Outlines the concept of customs supply chain with five building blocks and categorizes stakeholders into commercial, organizing, physical, authorizing, and financial categories (Elms & Low, 2013; Lamia et al., n.d.).
(Bartol, 2014; Ghadge et al., 2019; ISO/IEC, 2022; NDIA, 2008)	Standards and Guidelines in Cyber Supply Chain Security	Emphasizes the importance of collaboration among public, private, and academic stakeholders for securing Cyber Supply Chain Security (CSCS). Discusses standards and guidelines (Bartol, 2014; Ghadge et al., 2019; NDIA, 2008; ISO/IEC, 2022).
(Kim & Im, 2014; Lu et al., 2017; Pandey et al., 2020; Wang & Franke, 2020; Zage et al., 2013)	Specific Vulnerabilities and Risks in Cyber Supply Chain	Highlights detailed vulnerabilities and risks in Cyber Supply Chain Security (CSCS), including information sharing, change of supplier, and software vulnerabilities (Kim & Im, 2014; Lu et al., 2017; Pandey et al., 2020; Wang & Franke, 2020; Zage et al., 2013).

Table 2 Summary/Table 2meta-analysis of Reviewed of Related Works

This chapter provides an overview of the academic research available on this topic focusing on the elements of Data integrity in cyber supply chain security for customs operations. Since cyber supply chain security is a highly connected field this review covered a variety of topics. After reviewing the recent literature on cyber supply chain, the researcher determined that there were several missing elements. Based on the data integrity ontology the preventive defense of systems is very well researched.

However, there are gaps in the literature regarding Data integrity in cyber supply chain security for customs operations including vulnerabilities, investigation, containment, and recovery as well as gaps in understanding the methods, sources, intentions, and purposes of attackers. Literature on research methods was also reviewed in order to establish an appropriate method for conducting research into this topic area. The remainder of this study addressed the research methods, analysis, and resulting conclusions. The next chapter contains the research methodology for addressing these gaps.

CHAPTER THREE

RESEARCH METHODOLOGY

3.0 Preamble

In this chapter the details of this methodology are presented including the research design, sample, sample methods, and sample procedures, data collection, instrument design, measurements, and data analysis methods. The validity and reliability as well as ethical considerations are also discussed in this chapter.

3.1 Problem Formulation

The research addresses the critical issue of data integrity within the cyber supply chain security for customs operations. The main problems identified include vulnerabilities in existing systems that compromise data integrity, potentially leading to security breaches, fraudulent activities, and disruptions in customs operations.

3.2 Research Strategy

The investigation conducted for this research involves an applied approach, focusing on the critical domain of data integrity in cyber supply chain security for customs operations. While the topic itself is not novel, existing academic literature extensively covers Cyber supply chain security (Sobb et al., 2020). In contrast, this research signifies a novel contribution by exploring the dimensions of data integrity within the context of cyber supply chain security for customs operations. Consequently, the study is designed to address vulnerabilities and propose effective solutions in this specialized area, contributing to the advancement of knowledge in the field.

3.3 Research method

To achieve the objectives of this research, a quantitative research approach was employed. Quantitative research is particularly suitable for large-scale data analysis and provides measurable and quantifiable outcomes (Apuke, 2017). This methodology differs fundamentally from qualitative research, as it emphasizes the statistical analysis of numerical data over subjective interpretation.

The primary advantage of quantitative research lies in its capacity to generate comprehensive and objective insights into the research subject while allowing for the examination of a larger scope and diverse nature of participant responses (Apuke, 2017). In contrast to qualitative research, which heavily relies on the skills and interpretations of researchers, quantitative

research minimizes the influence of personal judgments, enhancing the reliability of outcomes (Bell, 2010).

Furthermore, the use of quantitative research is advantageous for a study focusing on data integrity in cyber supply chain security for customs operations. It enables the systematic collection and analysis of numerical data related to vulnerabilities and potential solutions, offering a more rigorous and generalizable approach to understanding the broader implications of the research findings.

3.4 Data Collection Method and Tools

A quantitative research approach was adopted to systematically investigate the numerical aspects of vulnerabilities and propose effective solutions also a Multinominal Logistics Regression model (MNLR) to investigate the relationship between different variables of the dataset. The primary data collection method employed for this research was structured surveys. These surveys were designed to gather quantitative insights from participants regarding their perspectives on data integrity within the realm of cyber supply chain security for customs operations. Structured surveys offer a standardized and replicable means of collecting numerical data, ensuring consistency in the research process and facilitating rigorous statistical analysis (Dillman et al., 2014).

Structured surveys were chosen over in-depth interviews to maintain a focus on quantitative measurements and statistical rigor. Unlike in-depth interviews, structured surveys provide a more systematic and efficient way to collect data from a larger sample size. The survey instrument used in this research comprised carefully crafted questions specifically aligned with the research objectives, covering key dimensions related to data integrity, cybersecurity, and customs operations. This approach enhances the reliability and generalizability of the research findings, allowing for a comprehensive exploration of vulnerabilities and identification of effective solutions within the context of cyber supply chain security for customs operations.

3.5 Sample Selection

For this research, a purposive sampling was employed to develop a sample that is directly relevant to the research context. Purposive sampling, as a non-probability sampling technique, involves selecting sample members based on their specific knowledge, relationships, and expertise related to the research subject (Collier et al., 2009).

In this study, the participants were chosen deliberately due to their direct or indirect involvement with customs online services. The sample comprises individuals with specialized

knowledge and experience in customs operations, including Customs Officers, Customs License Agents, Customs Technical Services Providers and IT professionals. These individuals were selected for their expertise and active engagement in the realm of customs operations, making them well-suited to provide valuable insights into the data integrity issues within the cyber supply chain for customs operations. The goal is to gather insights from individuals who are actively involved in or have a deep understanding of the challenges and solutions related to data integrity in the context of cyber supply chain security for customs operations.

3.5.1 Population

The population of this study encompasses professionals involved in customs operations, including ICT Specialists, Customs Officers, Customs Technical Support companies, Customs Agents, and other relevant stakeholders within the cyber supply chain for customs operations. As the focus is on data integrity, the population includes individuals engaged in various aspects of customs operations worldwide.

3.5.2 Sample Size and Sampling Technique

The sample size for this study consists of 108 participants drawn from the aforementioned population. The sampling technique employed is convenience sampling, which allows for the selection of participants based on their accessibility and willingness to participate (Fleetwood, 2024). Given the specialized nature of the subject matter and the need for timely data collection, convenience sampling provides a practical approach to recruit participants efficiently.

3.5.3 Research Instruments

The primary research instrument utilized in this study is a structured questionnaire. The questionnaire comprises a series of closed-ended questions designed to gather quantitative data on participants' perceptions, experiences, and opinions regarding data integrity in the cyber supply chain for customs operations. The questionnaire covers various aspects, including participants' roles, years of experience, perceptions of vulnerabilities, experiences with data integrity breaches, cybersecurity measures employed, and preferences for data integrity enhancement solutions.

3.5.4 Validity and Reliability of Research Instruments

To ensure the validity of the research instruments, the questionnaire underwent rigorous pre-testing and pilot testing phases. During these phases, the questionnaire was administered to a small sample of participants to assess its clarity, comprehensiveness, and relevance to the research objectives. Feedback obtained from the pre-testing and pilot testing processes was

used to refine and improve the questionnaire, enhancing its validity by ensuring that it effectively measures the intended constructs.

3.6 MNL Regression Model

The Multinomial Logistic (MNL) regression model is employed to analyze data integrity within cyber supply chain security for customs operations. Its flexibility in accommodating multiple choice alternatives allows for a nuanced examination of factors influencing vulnerabilities and solutions in cybersecurity measures. In this study, MNL model was employed to investigate perceptions of vulnerability, effectiveness of cybersecurity measures, and feasibility of implementing technological solutions. By incorporating socio-economic and operational variables such as years of experience and types of customs operations, the research aims to provide comprehensive insights into the intricate dynamics shaping data integrity within customs operations. Through coefficient estimation via maximum likelihood criterion, the research seeks to enhance cybersecurity protocols in the cyber supply chain, contributing to the broader discourse on safeguarding data integrity.

3.7 Data Analysis

In this study, a mixed-methods approach, combining MNL Regression Model, qualitative and quantitative data analysis techniques, was employed to analyze the data collected through the structured surveys administered to Customs Officers, Customs License Agents, and Customs Technical Services Providers.

3.7.1 MNL Regression Model

MNL modeling was adopted in the research because of its capability in estimating the mode shares where more than two choices of modes of Vulnerability perception are available for a participant.

Variables Used in the Study

The following variables were considered as a set of variables crucial for understanding the complex dynamics at play.

- **Dependent Variable:**

  Perception of Vulnerability: On a scale from 1 to 5, where 1 indicates "Not a Concern" and 5 indicates "Highly Concerning," respondents rated their perception of the vulnerability of data integrity in the cyber supply chain within customs operations.

- **Independent Variables:**

1. **Years of Working Experience:** The number of years respondents have worked in their respective roles within customs operations.
2. **Position/Role:** The specific role or position held by respondents within customs operations.
3. **Type of Customs Operations:** The nature or type of customs operations in which respondents are involved.

These variables were chosen to examine the relationship between perceptions of vulnerability and various socio-economic factors within customs operations, providing insights into the challenges and opportunities for enhancing data integrity in the cyber supply chain.

3.7.2 MNL Regression Analysis:

The MNL regression analysis conducted on the dataset yielded significant insights. Coefficients and odds ratios were estimated to quantify the impact of various factors on the perceived vulnerability levels. For instance, the coefficient (B) for a specific variable indicates the change in the log-odds of vulnerability perception associated with a one-unit change in that variable, while the odds ratio (Exp(B)) provides a more interpretable measure of effect size.

These findings contribute to understanding the intricate dynamics influencing data integrity within the cyber supply chain context, with implications for customs operations. For example, a significant odds ratio above 1 suggests a positive association between certain variables and vulnerability perception, highlighting areas warranting heightened attention and potential intervention strategies. Conversely, odds ratios below 1 indicate factors that may mitigate vulnerability perception, offering insights into protective mechanisms or best practices.

The chi-square statistic facilitated model comparison and assessment of fit, pinpointing areas where the inclusion or exclusion of specific variables enhances explanatory power. From the above analysis, the presence of a relationship between the dependent variable and combination of independent variables is based on the statistical significant of the final model Chi-square value.

The null hypothesis that there was no difference between the model without independent variables and model with independent variables is rejected. Thus, there exists sufficient evidence that a relationship between the independent variable and the dependent variable was statistically significant at 5% significance level.

- **Qualitative Analysis:**

Thematic Categorization: Qualitative data related to vulnerabilities and solutions in the cyber supply chain security for customs operations were systematically categorized into themes and sub-themes. This process allowed for a nuanced exploration of participants' perspectives.

Structuring Insights: Content analysis, inspired by (Ndongfack, 2015), was utilized to structure qualitative insights, ensuring that the data was organized in a manner aligned with the research objectives. This facilitated a comprehensive understanding of the qualitative aspects of data integrity within customs operations.

- **Quantitative Analysis:**

Quantification of Responses: Survey responses were quantified to enable numerical analysis, allowing for statistical examination of trends and patterns related to participants' perceptions of vulnerabilities and proposed solutions in the cyber supply chain for customs operations.

- **Software use**

Two main tools were used to perform the research:

a. Google Forms: google forms is used to create the survey.
b. IMB SPSS Software: the software is used to conduct the statistical tests and analysis

CHAPTER FOUR

RESULT AND DISCUSSION

4.0 Preamble

This section presents the outcomes of a comprehensive investigation into the realm of Data Integrity in Cyber Supply Chain Security for Customs Operations. Vulnerability and Solutions. The research methodology employed a structured questionnaire, with insights drawn from 108 participants. The chapter is organized as follows: System Evaluation, Results presentation, Analysis of the Results, Discussion of the Results, Implications of the results, Benchmark of the results (comparing current results with results from previous similar studies). The Survey commencing with an introduction, where participants position/role is assessed. The subsequent questionnaire delves into five categories of a conceptual framework, capturing perceptions of vulnerabilities and impacts of data integrity breaches. Participants reflect on challenges faced, leading to a summary of findings in Section 4.8.

The questionnaire comprises multiple sections, including demographic information, the identification of key vulnerabilities, analysis of the impacts of data integrity breaches, exploration of current cybersecurity measures, and proposals for enhancing data integrity. Participants were probed on their positions, years of experience, and the type of customs operations they engage in. Noteworthy questions included rating the vulnerability of data integrity, identifying critical vulnerabilities, sharing experiences of data breaches, and evaluating confidence in existing cybersecurity measures.

The presented findings aim to deepen understanding and inform strategies for enhancing data integrity in this critical domain.

4.1 System Evaluation

The evaluation of the research system employed is fundamental to comprehending the robustness of the methodology and framework. The research design primarily utilized a questionnaire-based approach, strategically crafted with multifaceted questions aligning with the research objectives. Participant recruitment targeted relevant stakeholders, and the inclusion of 108 participants enhances statistical robustness, though potential selection bias could exist due to the voluntary nature of participation. The questionnaire underwent rigorous development and pilot testing to ensure clarity and relevance.

Ethical considerations prioritized participant anonymity and confidentiality, with informed consent obtained. Despite these measures, limitations emerged, including the challenge of following up on anonymous responses and the potential for subjective interpretation in self-reported data. Robust data analysis methods, both quantitative and qualitative were employed as well as Multinominal Logistics Regression model, yet the complexity of certain responses and the subjective nature of qualitative analysis may introduce interpretation bias. Throughout the study, reflexivity was maintained, acknowledging the researcher's biases and perspectives to mitigate their impact on data interpretation. This comprehensive evaluation establishes transparency, laying the foundation for the subsequent presentation and analysis of research results while providing insights into the reliability and generalizability of the findings within the broader research context.

4.2 Results Presentation

This section provides a detailed and nuanced understanding of the key findings in each section of the Result Presentation based on the survey data.

4.2.1 Demographic Overview:

In analyzing the demographic profile of the 108 respondents, it is observed that the majority of participants identified as Customs Officers, constituting 44% of the sample. Following closely, Customs Technical Support companies comprised 21%, while Customs Agents and representatives from ICT Specialist represented 16% and 14%, respectively. Additionally, a small percentage fell into the 'Other' category, signifying a diverse range of roles within the customs operations landscape as shown in Figure 1. Regarding years of working experience, a significant portion (45%) reported 1-5 years, while 35% had 6-10 years of experience. A smaller percentage had more than 10 years (10%) or (9%) less than 1 year of experience. Importantly, the survey captured a comprehensive snapshot of participants involved in a spectrum of customs operations, including Import (28%), Export (14%), and ICT-related activities (47%) as shown in Figure 2.

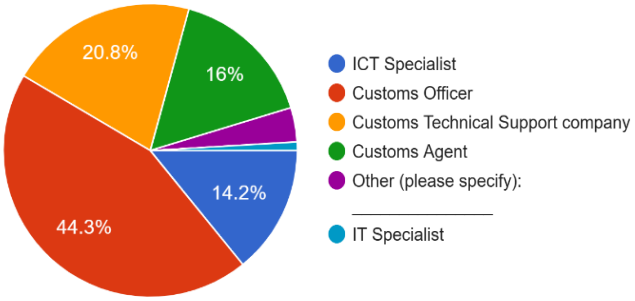

Figure 1 Position/Role

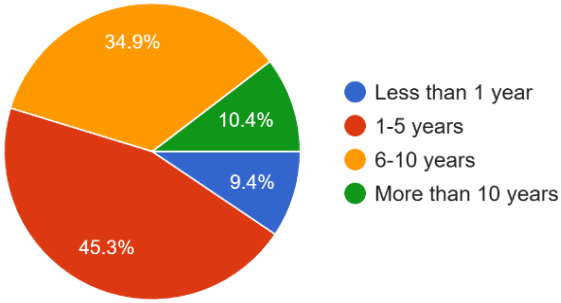

Figure 2 Years of working Experience

4.2.2 Objective 1: Identify Key Vulnerabilities:

As participants assessed the vulnerability of data integrity in the cyber supply chain for customs operations, the collective perception leaned toward concern, evidenced by a mean rating of 3.7 on a scale from 1 to 5. In dissecting the specific vulnerabilities, participants pointed to a range of critical issues. These included Lack of Regular Cybersecurity Training, Vendor and Third-Party Risks, Insufficient Physical Security Measures, inadequate authentication measures, insufficient encryption protocols, and the challenge of dealing with outdated software and systems. The identification of these vulnerabilities lays the foundation for understanding the intricacies and potential weak points in the current cyber supply chain security landscape as shown in Figure 3.

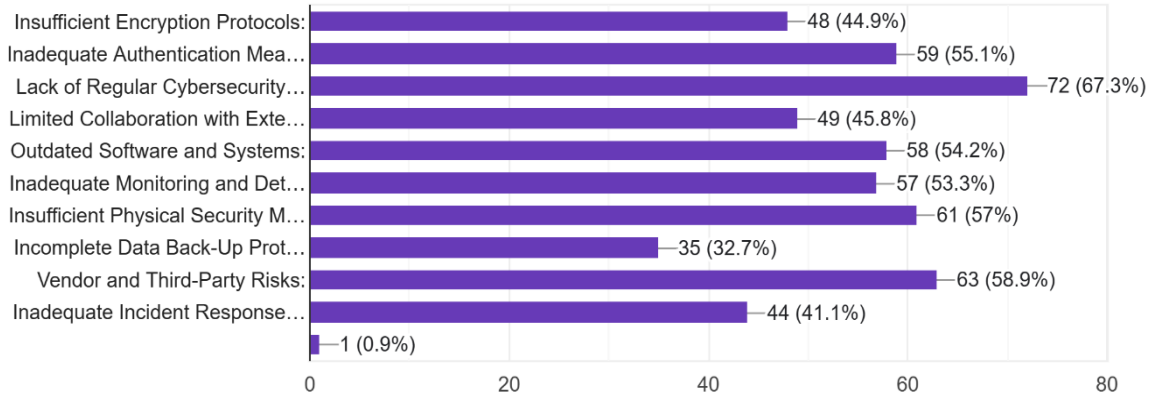

Figure 3 What do you believe are the most critical vulnerabilities that could compromise data integrity in the cyber supply chain for customs operations? (Check all that apply)

4.2.3 Objective 2: Analyze Impacts of Data Integrity Breaches:

A noteworthy finding emerged as approximately 37 respondents representing 38% of respondents reported having experienced data integrity breaches in the cyber supply chain for customs operations. When asked to elucidate the impacts of these breaches on organizational operations, respondents provided insights into a multifaceted set of consequences. These included financial losses, trade disruptions and delays, compromised national security, Erosion of public trust in customs operations and an increase in security risks as shown in Figure 4. This section provides a tangible understanding of the real-world ramifications of data integrity breaches within the surveyed population.

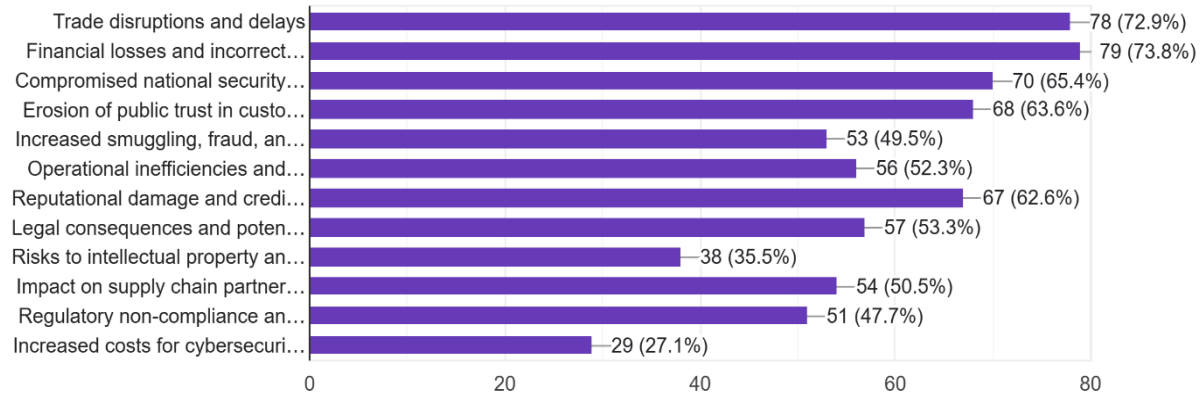

Figure 4 Please select the most applicable adverse impacts of data integrity breaches on customs operations and the broader supply chain: (Check all that apply)

4.2.4 Objective 3: Explore Cybersecurity Measures and Protocols:

Participants exhibited a low level of confidence (mean rating of 2.3) in the effectiveness of current cybersecurity measures and protocols in safeguarding data integrity within customs operations. Delving into the specifics, respondents outlined a range of measures commonly employed in their organizations. These encompassed access controls, encryption, data backups, multi-factor authentication, and regular security audits. Notably, participants identified encryption protocols, System software updates, regular cybersecurity training, data backup protocols, collaboration with external experts, and incident response planning as the most effective cybersecurity measures as shown in Figure 5. This insight contributes to the understanding of the existing cybersecurity landscape and sheds light on preferred strategies for data integrity protection.

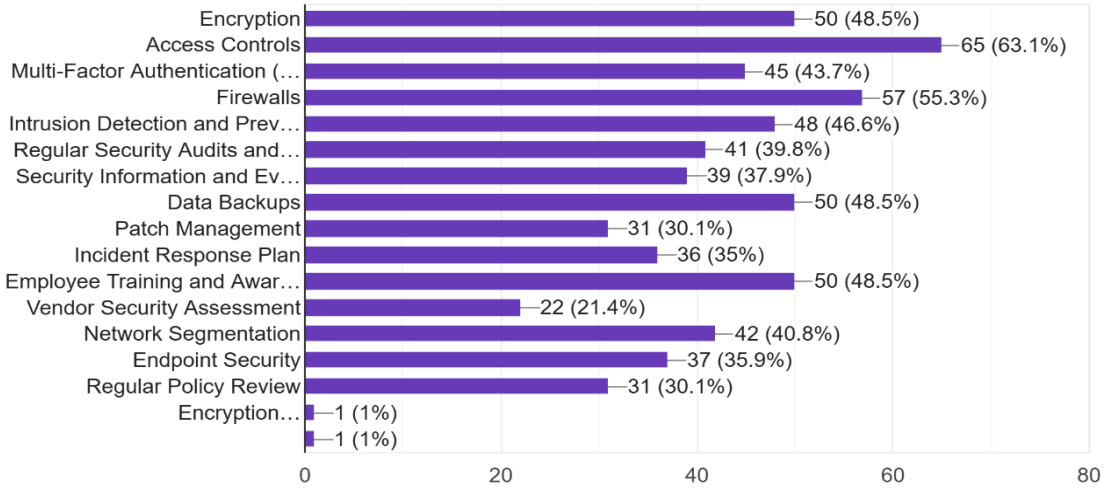

Figure 5 Please list the cybersecurity measures and protocols currently employed in your organization to maintain data integrity. (Check all that apply)

4.2.5 Objective 4: Propose Solutions for Data Integrity Enhancement:

Concerning the feasibility of implementing technological solutions for data integrity enhancement, participants provided a moderate rating (mean of 3.8). Their opinions on comprehensive solutions underscored the importance of Regular Cybersecurity Training for Staff, Adoption of Advanced Monitoring and Detection Systems, Implementation of blockchain technology, enhanced encryption protocols, and collaboration with external cybersecurity experts. Additionally, participants ranked solutions, with a clear preference for enhanced encryption protocols, Implementation of Blockchain Technology, Regular Cybersecurity Training for Staff and robust incident response planning as shown in Figure 6. This section illuminates the participants' perspectives on feasible and impactful strategies for bolstering data integrity within the cyber supply chain for customs operations.

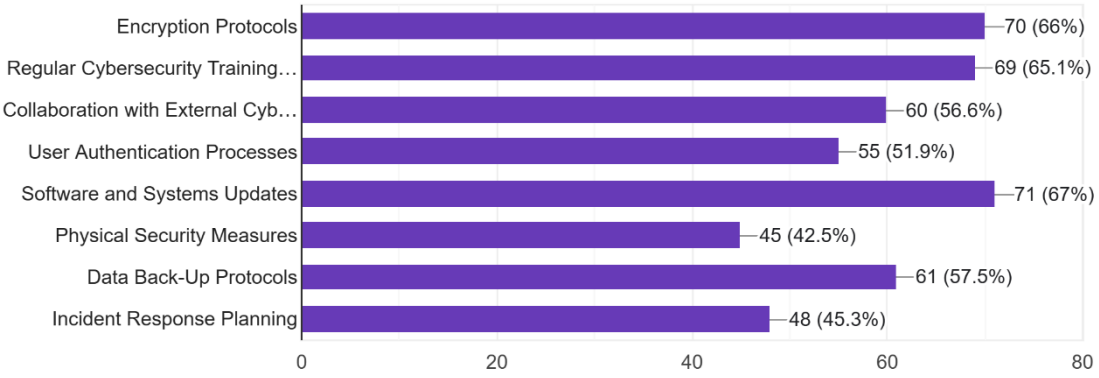

Figure 6 Which of the following cybersecurity measures do you think is most effective in ensuring data integrity in the cyber supply chain for customs operations?

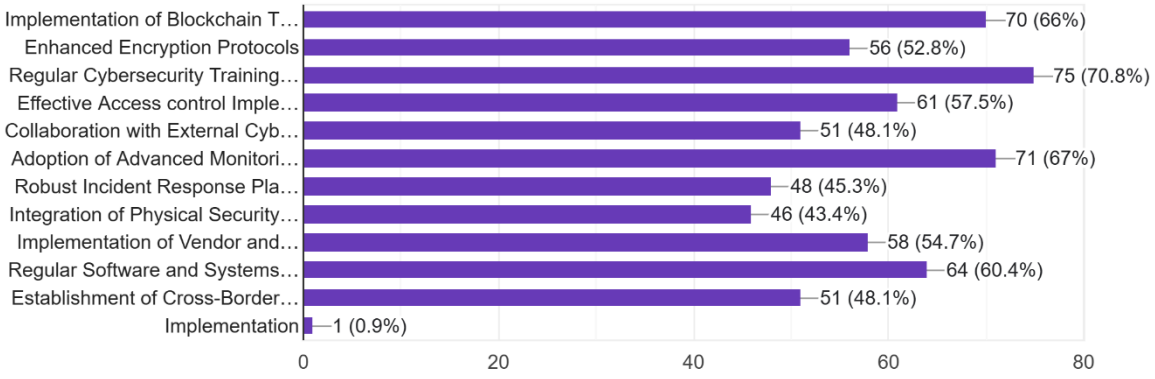

Figure 7 In your opinion, what comprehensive solutions do you believe would be effective in enhancing data integrity in the cyber supply chain for customs operations? (Check all that apply)

4.2.6 International Collaboration:

Finally, the survey probed participants on the extent to which they believed international collaboration and information sharing could contribute to enhancing data integrity in the cyber supply chain for customs operations. A substantial majority, constituting 62% of respondents, expressed a belief in the significant role of international collaboration in this context. This finding underscores the perceived importance of a global approach to addressing data integrity challenges, emphasizing the interconnected nature of cyber supply chains across borders.

4.3 Analysis of the Results

This analysis provides a deeper understanding of the implications of the presented results, connecting them to broader industry contexts and shedding light on potential areas for improvement and strategic focus within customs operations cybersecurity.

4.3.1 Multinominal Logistics Regression Analysis

The multinomial logistic regression analysis, indicates that the variables "Years of Working Experience," "Position/Role," and "Type of Customs Operations" do not significantly impact the perception of the vulnerability of data integrity in the cyber supply chain within customs operations.

Likelihood Ratio Tests

Effect	Model Fitting Criteria: -2 Log Likelihood of Reduced Model	Likelihood Ratio Tests: Chi-Square	df	Sig.
Intercept	105.419[a]	.000	0	.
Years of working Experience:	119.882[b]	14.462	16	.564
Position/Role:	123.467[b]	18.048	24	.801
Type of Customs Operations:	156.055	50.636	56	.677

Table 3 MNL Regression Model Fitting Information

- **Years of Working Experience:** The model shows no significant effect on the perception of data integrity vulnerability (Chi-Square = 14.462, df = 16, Sig. = 0.564). This high p-value suggests that the years of experience do not predict perceptions of vulnerability.
- **Position/Role:** This variable also does not significantly affect perceptions of data integrity vulnerability (Chi-Square = 18.048, df = 24, Sig. = 0.801). The high p-value indicates no significant relationship.

- **Type of Customs Operations:** This variable does not significantly influence perceptions of data integrity vulnerability (Chi-Square = 50.636, df = 56, Sig. = 0.677). The high p-value suggests no significant effect.

4.3.2 Demographic Overview

Analysis: The demographic overview reveals a diverse representation within the respondent pool, with Customs Officers being the majority. This diversity is crucial as it ensures a broad perspective on data integrity in the cyber supply chain for customs operations. The distribution across experience levels and types of customs operations further enriches the study, offering insights into varying perspectives based on roles and tenure (*Chapter 9 Survey Research | Research Methods for the Social Sciences*, n.d.).

4.3.3 Objective 1: Identify Key Vulnerabilities

Analysis: The mean rating of 3.7 indicates a collective perception of concern regarding data integrity vulnerabilities. The identified vulnerabilities, such as Lack of Regular Cybersecurity Training and Vendor Risks, align with industry-recognized challenges (Gurchiek, 2019). The emphasis on outdated software and systems underscores the need for technological updates. This section sets the stage for a deeper understanding of specific areas requiring attention in cybersecurity practices within customs operations.

4.3.4 Objective 2: Analyze Impacts of Data Integrity Breaches

Analysis: The reported 38% incidence of data integrity breaches substantiates the significance of the issue. The impacts, ranging from financial losses to compromised national security, underline the far-reaching consequences. Notably, the emphasis on erosion of public trust emphasizes the interconnectedness of cybersecurity and public perception, an essential consideration for customs operations.

4.3.5 Objective 3: Explore Cybersecurity Measures and Protocols

Analysis: The low mean rating of 2.3 in confidence regarding current cybersecurity measures signals a perceived inadequacy. Participants' preference for encryption protocols, regular cybersecurity training, and collaboration with external experts indicates a desire for a multifaceted approach. The identified effective measures align with industry best practices, emphasizing a need for continuous improvement and adaptation in cybersecurity strategies.

4.3.6 Objective 4: Propose Solutions for Data Integrity Enhancement

Analysis: The moderate feasibility rating of 3.8 indicates cautious optimism toward implementing technological solutions. The prioritization of Regular Cybersecurity Training,

Adoption of Advanced Monitoring Systems, and enhanced encryption aligns with proactive cybersecurity strategies. The clear preference for certain solutions suggests a roadmap for organizations seeking to enhance data integrity in the cyber supply chain for customs operations.

4.3.7 International Collaboration

Analysis: The strong belief (62%) in the role of international collaboration underscores a global perspective on cybersecurity challenges. Recognizing the interconnected nature of cyber supply chains and the potential benefits of information sharing, this finding suggests that collaborative efforts could play a pivotal role in fortifying data integrity in customs operations.

4.4 Discussion of the Results

The examination of the results illuminates crucial aspects of data integrity in the cyber supply chain for customs operations. This comprehensive discussion delves into key findings, their implications, and potential avenues for further exploration.

4.4.1 Multinominal Logistics Regression:

The analysis consistently indicates that the independent variable (perception of the vulnerability of data integrity) is not significantly influenced by the dependent variables (Years of Working Experience, Position/Role, and Type of Customs Operations). Future research should broaden the scope of investigation to include other possible determinants to develop a more comprehensive understanding of the factors influencing these perceptions.

4.4.1 Demographic Overview:

The diverse demographic composition of respondents is noteworthy, with Customs Officers constituting the majority. This diversity ensures a holistic view of data integrity challenges within customs operations. The distribution across experience levels and customs operations types adds granularity to our understanding, allowing for nuanced insights into the perspectives of different roles and tenures.

This demographic diversity is crucial in interpreting the findings, as it reflects the broader landscape of professionals engaged in customs operations (Nynikka & Esteban, 2023). It suggests that the identified vulnerabilities, impacts, and proposed solutions are representative of a spectrum of roles within the field.

4.4.2 Objective 1: Identify Key Vulnerabilities:

The mean rating of 3.7, signifying a collective concern about data integrity vulnerabilities, highlights the significance of the issue within the customs operation's community. The

identified vulnerabilities align with industry-recognized challenges, emphasizing the importance of addressing these specific areas to enhance the overall cybersecurity posture.

Particular attention should be directed towards Lack of Regular Cybersecurity Training and Vendor Risks, as these emerged as critical vulnerabilities. This highlights the need for continuous education and awareness programs, along with robust vendor risk management practices.

4.4.3 Objective 2: Analyze Impacts of Data Integrity Breaches:

The reported 38% incidence of data integrity breaches corroborates the industry trend of increasing cyber threats. The multifaceted impacts, from financial losses to compromised national security, emphasize the far-reaching consequences of such breaches. Notably, the emphasis on erosion of public trust underscores the interconnectedness of cybersecurity and public perception, emphasizing the need for not only technical but also reputational safeguards. This finding necessitates a holistic approach to cybersecurity, recognizing that breaches not only impact operations and finances but also have broader implications for organizational reputation and public trust.

4.4.4 Objective 3: Explore Cybersecurity Measures and Protocols:

The low mean rating of 2.3 in confidence regarding current cybersecurity measures signals a perceived inadequacy in the existing strategies. The preference for encryption protocols, regular cybersecurity training, and collaboration with external experts indicates a collective desire for a multifaceted and proactive approach to cybersecurity.

Organizations within customs operations should consider revisiting and strengthening their cybersecurity measures, focusing on the identified effective strategies. Regular training and collaboration could play pivotal roles in enhancing the overall cybersecurity posture.

4.4.5 Objective 4: Propose Solutions for Data Integrity Enhancement:

The moderate feasibility rating of 3.8 suggests a cautious optimism toward implementing technological solutions. The prioritization of Regular Cybersecurity Training, Adoption of Advanced Monitoring Systems, and enhanced encryption aligns with proactive cybersecurity strategies. This presents a roadmap for organizations seeking to fortify data integrity in the cyber supply chain for customs operations.

The discussion surrounding solutions underscores the practicality and potential effectiveness of certain measures. Organizations can leverage these insights to tailor their cybersecurity enhancement initiatives, with a focus on the most feasible and impactful strategies.

4.4.6 International Collaboration:

The strong belief (62%) in the role of international collaboration highlights the interconnected nature of cybersecurity challenges in the customs operation's domain. This finding underscores the potential benefits of global information sharing and collaborative efforts in fortifying data integrity.

Customs organizations should explore opportunities for international partnerships and information exchange to collectively address the evolving landscape of cybersecurity threats. A shared approach could lead to more robust defenses against cyber threats that transcend national borders.

4.5 Limitations and Future Research:

This study has limitations, which should be addressed in prospective studies. In prospective studies, much more comprehensive models can be built adding new factors to the model. Transforming the dependent variable into an ordered categorical structure, ordered logit models can be applied to the subject matter, which can be contrasted with multinomial logit models for goodness of fit. In conclusion, this discussion provides a nuanced interpretation of the results, offering actionable insights for customs organizations aiming to enhance data integrity in their cyber supply chains. The findings serve as a foundation for future research and as a guide for organizations seeking to fortify their cybersecurity practices in an ever-evolving digital landscape.

4.6 Implications of the results

The findings of this research carry significant implications for the field of customs operations, particularly in the context of bolstering data integrity within the cyber supply chain. The diverse demographic profile of respondents, predominantly comprising Customs Officers, underscores the need for tailored approaches that cater to the varying roles within the sector. Understanding the nuances of data integrity challenges across experience levels and types of customs operations is imperative for implementing effective and targeted cybersecurity measures.

The identification of key vulnerabilities, as indicated by the mean rating of 3.7, highlights a shared concern among participants. This collective apprehension suggests a recognized need for proactive measures to address these vulnerabilities. Notably, the emphasis on Lack of Regular Cybersecurity Training and Vendor Risks implies a crucial need for continuous education programs and robust vendor risk management protocols. Implementing targeted

interventions in these specific areas could significantly enhance the overall cybersecurity posture of customs operations.

The revelation that 38% of respondents have experienced data integrity breaches underscores the urgency of addressing cybersecurity challenges. The multifaceted impacts, ranging from financial losses to compromised national security and erosion of public trust, necessitate a comprehensive and resilient cybersecurity strategy. Customs organizations must recognize the interconnected nature of cybersecurity and public perception, acknowledging that breaches not only impact operational efficiency but also have broader implications for trust and reputation.

The low confidence level (mean rating of 2.3) in current cybersecurity measures implies a perceived inadequacy in the existing strategies. The preference for specific measures such as encryption protocols, regular cybersecurity training, and collaboration with external experts indicates a collective desire for a multifaceted and proactive approach. Customs organizations should view this as an opportunity to reassess and strengthen their cybersecurity measures, with a focus on these identified effective strategies.

Regarding the feasibility of implementing technological solutions, the moderate rating of 3.8 suggests cautious optimism among participants. The prioritization of Regular Cybersecurity Training, Adoption of Advanced Monitoring Systems, and enhanced encryption provides a practical roadmap for organizations. While organizations express openness to technological solutions, they should approach implementation with a strategic mindset, ensuring feasibility and impact align with organizational goals.

The strong belief (62%) in the role of international collaboration signifies a global perspective on cybersecurity challenges within customs operations. This finding implies that customs organizations recognize the interconnected nature of cyber threats and understand the potential benefits of global information sharing. Actively seeking international partnerships and exploring collaborative frameworks could be instrumental in fortifying data integrity on a broader scale.

In conclusion, these implications offer valuable guidance for customs organizations aiming to navigate the complex landscape of cybersecurity. Tailoring interventions to address specific vulnerabilities, acknowledging the broader impacts of breaches, strengthening existing measures, strategically implementing technological solutions, and fostering international collaboration emerge as key pathways toward fortifying data integrity in the cyber supply chain for customs operations.

4.7 Benchmark of the results (comparing current results with results from previous similar studies) –

In the realm of cybersecurity, thist research, anchored in the exploration of "Data Integrity in Cyber Supply Chain Security for Customs Operations, Vulnerabilities, and Solutions," converges and diverges with a prior study titled "Cyber Supply-Chain Security Challenges in the Context of Interorganizational Collaboration." This comparative analysis endeavors to shed light on the unique dimensions uncovered by each study, enriching our comprehension of data integrity challenges within the intricate tapestry of cyber supply chains.

4.7.1 Methodologies: Interviews and Questionnaires.

The previous research opted for a qualitative approach, conducting four interviews within the realm of Swedish government organizations. This choice facilitated an in-depth exploration, offering nuanced insights into the challenges of Cyber Supply-Chain Security (CSCS) within a specific context. In contrast, the current research employed a quantitative methodology, utilizing questionnaires to draw responses from a diverse pool of 108 participants. This approach, spanning Customs officers, Customs technical service providers, Customs Agents, and ICT professionals, provided a mosaic of perspectives within the customs operations landscape. The quantitative nature of the questionnaire allowed for a broader sampling of opinions and experiences, enriching the overall understanding of data integrity vulnerabilities and potential solutions.

4.7.2 Tailored Approaches for Customs Operations:

The distinct organizational challenges illuminated in the previous research, where vendor organizational sizes present unique hurdles, resonate with our current exploration of customs operations. Acknowledging the diversity of roles within this landscape becomes paramount as we delve into the vulnerabilities and solutions intricately woven into the fabric of data integrity.

4.7.3 Holistic Security Strategies:

Challenging the conventional notion of evaluating supply chains as mere "weakest links," the prior research emphasizes the importance of additional security measures. While not explicitly addressed in our current research, this perspective prompts contemplation on the multifaceted strategies required for safeguarding data integrity within customs operations. It introduces a thought-provoking layer to our understanding, emphasizing a holistic approach beyond singular vulnerabilities.

4.7.4 Multidisciplinary Threads in Cybersecurity Challenges:

Both studies converge in recognizing the multidisciplinary nature of cybersecurity challenges. From information security to Cyber Supply-Chain Risk Management, the puzzle pieces of cybersecurity intricacies are unveiled. Our current research echoes this sentiment within the customs operation's context, emphasizing the convergence of challenges across diverse domains within the cyber supply chain.

4.7.5 Common Categories Shaping Cybersecurity Challenges:

The categorization of challenges emerges as a common thread in both studies, revealing consistent dimensions such as communication, life cycle, points of penetration, cyber security objectives, and multiple vendors. These shared elements provide a foundational understanding, allowing us to identify key dimensions shaping challenges faced in interorganizational collaborations and customs operations.

4.7.6 Geographical and Organizational Focus: Tailored Perspectives:

The previous research, centered on Swedish government organizations, offered a geographically specific lens into CSCS challenges in the context of interorganizational collaboration. On the other hand, our current research focuses on Nigeria Customs Services, encompassing various roles within its operations. This nuanced difference allows for tailored perspectives on data integrity challenges within distinct organizational landscapes.

4.7.7 Practical Implications for Cybersecurity Practices:

Both studies offer practical implications for enhancing cybersecurity practices. The previous research's emphasis on the devastating consequences of Cyber Supply-Chain Security resonates with our recognition of the real-world ramifications of data integrity breaches in customs operations. Together, these insights pave the way for future research directions, inviting a continued exploration of emerging trends and practical strategies for mitigating cybersecurity challenges in the dynamic landscape of customs operations.

In conclusion, the comparative exploration of these two research endeavors provides a captivating panorama of data integrity challenges within cyber supply chains. From tailored organizational approaches to holistic security strategies, the insights garnered contribute to the evolving narrative of cybersecurity in interconnected supply chains and customs operations.

CHAPTER 5

SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Summary

In this comprehensive exploration, the research aimed to unravel the intricacies of data integrity within the cyber supply chain for customs operations, focusing on vulnerabilities and potential solutions. Engaging a diverse cohort of 108 participants, including Customs officers, technical service providers, Agents, and ICT professionals, the study unfolded across four key objectives. The demographic overview painted a vivid picture of the customs operations landscape, revealing the diverse roles, experiences, and operational domains within our respondent pool. From this varied perspective, we delved into the core of our research, identifying key vulnerabilities perceived by participants. The concerns echoed through insufficient encryption protocols, authentication challenges, and outdated software, setting the stage for a nuanced understanding of the cyber supply chain's weak points.

Moving beyond perception, we examined the real-world impacts of data integrity breaches, discovering that approximately 38% of respondents had experienced such incidents. The fallout encompassed financial losses, trade disruptions, and threats to national security, underscoring the gravity of these breaches on organizational and broader supply chain operations. A critical evaluation of current cybersecurity measures exposed a prevalent lack of confidence among participants. Encryption protocols, software updates, and collaboration with external experts emerged as focal points for potential improvement. Meanwhile, our exploration of the feasibility of technological solutions for data integrity enhancement received a moderate rating, guiding us toward areas of strategic focus for future implementations.

In the analysis phase, mean ratings, qualitative responses, and categorical preferences were dissected to distill actionable insights. This analytical lens allowed us to discern patterns, correlations, and emerging trends, enriching our understanding of the multifaceted cybersecurity landscape within customs operations. Our discussion delved into the implications of our findings, situating them within the broader cybersecurity discourse. By drawing connections between our outcomes and industry-specific considerations, we illuminated the practical significance of identified vulnerabilities and proposed solutions. Through this research, we not only shed light on the challenges faced by customs operations but also provided a valuable platform for ongoing dialogue and practical advancements in the ever-evolving realm of cybersecurity.

5.2 Conclusion

In conclusion, this research on Data Integrity in Cyber Supply Chain Security for Customs Operations, Vulnerabilities, and Solutions has uncovered critical insights into the state of cybersecurity within the customs domain. The rich tapestry of perspectives from Customs officers, technical service providers, Agents, and ICT professionals has provided a subtle understanding of the challenges and opportunities inherent in safeguarding data integrity.

The identified vulnerabilities, ranging from encryption concerns to authentication challenges, underscore the pressing need for strategic interventions. The real-world impacts of data integrity breaches, as reported by a significant percentage of respondents, highlight the tangible consequences on financial stability, trade continuity, and national security.

While current cybersecurity measures were met with skepticism among participants, specific strategies such as encryption protocols, software updates, and collaborative efforts with external experts have emerged as focal points for improvement. The feasibility of implementing technological solutions, though moderately rated, serves as a roadmap for future enhancements.

The analysis phase allowed us to distill actionable insights, discern patterns, and understand the intricacies of the cybersecurity landscape within customs operations. By drawing connections between our findings and the broader discourse, our research contributes not only to academic knowledge but also to practical advancements in the field.

In essence, this study serves as a catalyst for ongoing dialogue and strategic advancements in the dynamic intersection of customs operations and cybersecurity. As the cyber supply chain continues to evolve, our research provides a foundation for informed decision-making, laying the groundwork for resilient and secure customs practices in the digital era.

5.3 Recommendations

Based on the findings of the research on Data Integrity in Cyber Supply Chain Security for Customs Operations, Vulnerabilities, and Solutions, the following recommendations are proposed to enhance the cybersecurity posture within customs operations:

1. **Strengthen Encryption Protocols:**

Nigeria Customs Service should prioritize the implementation of robust encryption protocols to safeguard data during transmission and storage. Regular assessments and updates to encryption standards are essential to counter emerging threats.

2. **Enhance Cybersecurity Training:**

Establish comprehensive and regular cybersecurity training programs for customs officers, technical service providers, agents, and ICT professionals. This will empower personnel with the knowledge and skills needed to identify and mitigate cybersecurity risks effectively.

Facilitate Collaboration with External Experts:

NCS should actively seek collaboration with external cybersecurity experts and stay abreast of industry best practices. Engaging with external specialists can provide fresh insights, proactive threat intelligence, and a collaborative approach to addressing evolving cyber threats.

3. **Implement Multi-Factor Authentication (MFA):**

Enforce the adoption of multi-factor authentication across customs operations to add an extra layer of security. MFA mitigates the risk of unauthorized access, especially considering the sensitive nature of customs data.

4. **Regular Software and Systems Updates:**

Prioritize the timely updating of software and systems to address vulnerabilities and ensure that customs operations are running on secure and up-to-date technology stacks.

5. **Develop and Test Incident Response Plans:**

Establish robust incident response plans tailored to the unique challenges of customs operations. Regularly test and update these plans to ensure a swift and effective response in the event of a data integrity breach.

6. **Explore Blockchain Technology:**

Investigate the feasibility of implementing blockchain technology within the customs supply chain. Blockchain can enhance data integrity by providing a tamper-proof and transparent ledger, reducing the risk of fraudulent activities.

7. **Foster Cross-Border Information Sharing:**

Actively participate in international collaborations and information-sharing frameworks to create a united front against cyber threats. Shared intelligence and best practices can enhance the overall cybersecurity resilience of customs operations globally.

8. **Regular Cybersecurity Audits:**

Conduct regular cybersecurity audits and assessments to identify potential vulnerabilities and areas for improvement. Continuous monitoring and evaluation are critical components of a proactive cybersecurity strategy.

9. **Invest in Advanced Monitoring and Detection Systems:**

Explore and invest in advanced monitoring and detection systems to proactively identify and respond to potential cyber threats in real-time. This proactive approach can significantly reduce the impact of data integrity breaches.

These recommendations are designed to provide a holistic and proactive approach to enhancing data integrity in the cyber supply chain for NCS operations, ensuring a resilient and secure framework in the face of evolving cyber threats.

5.4 Contribution to the study

The research on "Data Integrity in Cyber Supply Chain Security for Customs Operations, Vulnerabilities, and Solutions" contributes significantly to the existing body of knowledge in several key areas.

Firstly, the study enhances understanding of cyber supply chain vulnerabilities by surveying 108 participants from diverse roles, addressing the narrow focus of previous work like (Filho et al., 2021), which mainly concentrated on technical aspects.

Secondly, it documents real-world impacts of data integrity breaches from 37 respondents, offering empirical evidence of financial losses, trade disruptions, and compromised security, thus substantiating theoretical frameworks proposed by (Anre Garrett, 2022).

Thirdly, the study evaluates current cybersecurity measures and protocols, providing a practical assessment of their effectiveness based on participants' confidence levels and preferences. This builds on the work of (Politeknik Mukah Sarawak, Sarawak, Malaysia et al., 2021) , who discussed strategies without practical evaluations.

Lastly, it proposes feasible solutions for enhancing data integrity, such as regular training and advanced monitoring systems, offering detailed, actionable plans that were lacking in previous studies like (Cyb, 2023).

By addressing significant gaps, providing empirical data, and offering practical solutions, this research is invaluable for NCS, policymakers, and cybersecurity practitioners seeking to improve data integrity in the digital landscape.

5.5 Future Research Directions

In conclusion, this research provides a foundation for future investigations into the dynamic landscape of cybersecurity within customs operations. To deepen our understanding over time,

longitudinal studies tracking the evolution of challenges are recommended. Additionally, cross-industry comparative analyses could unveil adaptable strategies, while exploring the behavioral aspects of cybersecurity among customs personnel would inform targeted training initiatives. The integration of Artificial Intelligence (AI) and Machine Learning (ML) technologies stands as a promising avenue for enhancing threat analysis and response mechanisms. Proposing global cybersecurity frameworks tailored for NCS operations would foster international collaboration. Further research should quantitatively assess the economic impacts of data integrity breaches and delve into the legal and regulatory landscape governing cybersecurity in NCS. User-centric design principles for cybersecurity tools, resilience testing, and simulation exercises within customs operations could be explored to enhance usability and response preparedness. Investigating emerging technologies like the Internet of Things (IoT) for supply chain transparency may contribute to a more secure and transparent customs ecosystem. By addressing these future research directions, we can advance the field, offering innovative solutions and proactive strategies to mitigate evolving cybersecurity threats within customs operations.

NATIONAL OPEN UNIVERSITY OF NIGERIA
ACETEL

A ZERO TRUST SECURITY IMPLEMENTATION MODEL IN DECENTRALIZED NETWORKS FOR INSTITUTION OF HIGHER LEARNING.

BY NALWADDA DOROTHY
ACE21120011
UGANDA(KAMPALA)

SUPERVISED BY

Professor IDRIS ISMAILA

A THESIS TO BE SUBMITTED TO NATIONAL OPEN UNIVERSITY OF NIGERIA, IN PARTIAL FULFILMENT OF THE REQUIRMENTS FOR THE AWARD OF THE MASTERS OF SCIENCE IN CYBER SECURITY

July 2024

Declaration

I hereby declare that this thesis is my contribution to the Master of Science in Cyber Security program and that, to the best of my knowledge, it contains no material that has been previously published by another person or material that has been accepted for the award of any other University degree, except where appropriate acknowledgment has been made in the text.

Signed: _____  _____ Date: _____25/July/2024_____

DOROTHY NALWADDA – ACE21120011

Certification/ Approval

This project work was written, arranged and compiled by Dorothy Nalwadda with the Registration number ACE21120011 under the supervision of Prof. Idris Ismaila in partial fulfillment for the award of a Master of Science in Cyber Security.

Signed: _____ Date: 25/7/2024

PROF. IDRIS ISMAILA

Acknowledgement

I express my gratitude to all my professors and the director ACETEL for the invaluable support given during my stay in the course. I greatly appreciate my classmates who have been very supportive especially through the whatsapp group to give me updates about the course. I cannot forget to thank World Bank for giving us the opportunity to study Masters on an international Level. All the support granted to us is highly appreciated and may the good LORD bless them all. I thank my supervisor Professor IDRIS ISMAILA and all faculty members who took time to guide and review my work to completion, all the time is appreciated. Lastly, I thank my family for the support and thank Makerere University for providing space for us to sit and access internet for our research. All ACETEL and NOUN management are highly appreciated. I am grateful to you for your encouragement and support throughout our study. Finally, to all my friends who contributed in diverse ways to making this project a reality, I say God bless

ZT - Zero Trust

ZTS- Zero Trust Security

MFA- Multifactor Authentication

LPA- Least Privileged Access

ZTNA- Zero Trust Network Architecture

Abstract

As institutions of higher learning increasingly rely on decentralized network resources to support their academic, administrative, and research activities, ensuring the security and integrity of these networks becomes paramount. This abstract discusses the methodology and results of implementing a Zero Trust security approach in the context of decentralized network resources for institutions of higher learning. The study began with a comprehensive assessment of the existing network infrastructure, identifying potential vulnerabilities and attack vectors that could compromise data security. A cross-functional team of cybersecurity experts, network administrators, and IT professionals collaborated to design and implement the Zero Trust security model. The first step was to define the access control policies based on the principle of "never trust, always verify." This involved mapping out the various user roles within the institution and the resources they needed to access. Additionally, an inventory of devices and applications used across the decentralized network was created. Next, a multifactor authentication (MFA) system was deployed to ensure that only authorized users could access sensitive data and resources. MFA added an extra layer of security, requiring users to verify their identities through multiple factors, such as passwords, biometrics and tokens. In conclusion, implementation of ZTS in decentralized network resources for institutions of higher learning proved to be highly effective in enhancing cybersecurity measures. The methodology and results of this study demonstrate the value of Zero Trust in safeguarding sensitive data, maintaining academic continuity, and protecting the institution from evolving cyber threats. As educational institutions continue to face challenges in securing their digital infrastructure, embracing a Zero Trust approach can provide a robust and adaptable security framework for a safer and more productive academic environment.

Chapter 1 INTRODUCTION

1.1. Background to the study

Zero Trust (ZT) stands out as a favored security approach for both corporate entities and governmental organizations (Deshpande et al., 2021). Institutions of Higher Leaning implement Zero trust for records management (assignments, presentations, tests and examinations) and other application (Dwivedi et al.,2020). Organizations frequently find themselves uncertain about the initial steps for implementing Zero Trust, focusing on foundational shifts in strategy and design required by the Zero Trust approach (Jewell et al., 2022). The research can be applicable in fields of government institutions for successful zero trust implementations (Atiff et al., 2021). The students and staff appreciate adopt without hurting students experience and differ access privilege, identity and access management. The Zero Trust (ZT) model prioritizes a data and identity-centric approach over a network-focused one, emphasizing the development of capabilities for enhanced visibility across users, applications, and data spanning various devices (Loukkaanhuhta, 2021). Consequently, it enforces policies regardless of whether the devices are connected to corporate networks (Mehraj & Banday, 2020). One of the difficulties associated with Zero Trust is that malicious actors can find ways to circumvent the system, giving users a temporary respite from potential threats (Nyamasvisva et al., 2020). The ZT pillars together in the context of Institutional Higher Education consider critical applications, data, and assets. Zero Trust is used in identity and access management technologies that solve Higher Institution of Learning (DelBene et al., 2019). The ZT adopts the Zero Trust IAM (Identity and Access Management), security professionals' solution to access problems. The likelihood of project approval, funding, and successful completion is enhanced by the incorporation of multifactor authentication and single sign-on (SSO) (Zhang et al., 2021). Implementing these measures not only addresses compliance, security, and productivity concerns but also necessitates an annual proof/access review process in Institutes of higher learning. During this process, managers, along with applications and data owners (Villareal, 2021), scrutinize user entitlements, either granting or revoking access within an identity management and governance platform. Furthermore, in the context of Zero Trust authentication, it becomes imperative for Institutes of higher learning to ensure that privileged users only have access to the necessary admin functions for their roles. Notably, Zero Trust retires the use of passwords in institutional applications, eliminating vulnerabilities associated with passwords that are susceptible to snooping, cracking, and stuffing

(Mehraj & Banday, 2020).Higher Learning Institutions use a minimum of Multi-Factor Authentication that protects critical applications and data assets (Liluashvili,2021). Using password less authentication methods such as biometrics, tokens, or keys, reduce the surface of man-in-the-middle attacks and noted vendors to include, Google, Ivanti, Microsoft, Okta, and others deliver solutions. A robust cloud governance structure, not only bolsters security but also guarantees comprehensive coverage across all cloud environments - on-premises, private, and public. This, in turn, extends Zero Trust's benefits beyond security, encompassing cost optimization, regulatory compliance, and enhanced threat detection. Transactions on cloud-platforms consider cloud-native security and management solutions (Mehraj & Banday, 2020). Cloud computing emphasizes the importance of establishing a sound governance structure to address issues like data sprawl, insufficient data protection, high costs, and audit findings. In public cloud usage, configurations are often insufficient, and there is limited protection for on-premises workloads as needed(Sneider,2021).Expanding insights into Zero Trust on cloud platforms highlight that cloud migrations present significant opportunities to re-platform, reconfigure, or refactor applications, incorporating cloud-native storage, databases, containerization, and logging practices.The application of ZT can liable to segmentation to manage devices (Sheikh et al., 2021) and can be used to quarantine potentially infected or compromised devices from propagating malware hence reducing risk of cyber security incidents. Zero Trust can be used to reduce user risk created by BYOD (Bring Your Own Device) policies. (Morolong et al., 2020; Stafford, 2020) to connect enterprise network and access data. Ends points ensure security through end points that present malicious software infections, ransomware events, and malware. Higher institutions ensure secure implementation by allowing them (eg backdoor and virus programs and software updates especially those related to security) to connect to the network or access systems (Jusas et al.,2021). The use of the zero-trust paradigm ensures a need to shut down all the non-used and threat-riddled apps your users want to run on their BYOD devices (Mehraj & Banday, 2020). Ensuring the data integrity of employed IoT devices involves incorporating features such as secure firmware, trusted execution environments, and obscured binary modification. These measures aim to reduce the likelihood of device and data tampering, as well as unauthorized access. In the context of Zero Trust, segmentation policies are taken into consideration, delineating access permissions between different groups, including associated hosts, peers, and services. This strategy defines and restricts access based on specified policies and trust levels, enhancing overall security. Zero Trust uses modern enterprise firewalls to augment cloud security controls (Mehraj & Banday, 2020). The next-generation

firewall (NGFW) was the backbone for Zero Trust. Next-generation firewalls are equipped with cryptographic chips to decrypt and analyze all data passing through a boundary. Enhance your application traffic inspection by incorporating a tier of autoscaling virtualized firewalls behind a gateway load balancer, as recommended by Abdalla et al. (2022). Higher Learning Institutions Integrate management of container security policies and cloud firewalls into their cloud-delivered or cloud-connected security dashboards, signaling a path forward. Devised push control approaches leverage north-south perimeter for human-generated traffic for risk clicks and malware and applicable in Domain Name Servers. The growing prominence of cloud computing, remote work, and the Internet of Things (IoT) has challenged traditional perimeter-based security models in higher institutions of learning. These decentralized environments expose data and information to diverse attacks, demanding a shift towards more dynamic and granular security approaches. Zero Trust, a security paradigm built on "never trust, always verify," emerges as a powerful solution for safeguarding institutions in this evolving landscape. Zero Trust, a security paradigm built on "never trust, always verify," emerges as a powerful solution for safeguarding institutions in this evolving landscape. (The Zero Trust Association, 2023). Traditional security methods rely on a clearly defined network perimeter to protect against external threats while maintaining trust in within entities. Decentralized networks, on the other hand, obfuscate these distinctions by distributing resources among multiple sites and access points. This leaves sensitive data and systems exposed and makes it is challenging to recognize and manage trusted entities.This strategy is turned on its head by Zero Trust. Regardless of where an access attempt originates, it constantly validates all of them and makes no implicit trust assumptions. Three fundamental ideas can be derived from this principle: Prior to gaining access to any resource, all users, devices, and applications must be authenticated and permitted.Applications and users are only given the minimal amount of access necessary to do their tasks. Zero Trust provides a robust security model for decentralized networks in institutions. By shifting focus from perimeter defense to continuous verification and least privilege access, institutions can significantly enhance their security posture and adapt to the evolving digital landscape. While challenges exist, the potential benefits for data protection, user privacy, and overall digital resilience make Zero Trust a worthwhile investment for institutions embracing decentralized technologies.

1.2. Statement of the problem

The Introduction of Information Technology (IT) systems within Higher-level Education administration has increased cybersecurity challenges due to the evolving skills of hackers and malicious actors (Desouza et al., 2020). Traditional perimeter-based network security measures are no longer sufficient, especially with the increasing trend of remote learning among students, which blurs the concept of a defined perimeter (Ameer et al., 2022). Consequently, there is a pressing need to devise effective security strategies that do not rely on implicit trust in the system, leading to the emergence of Zero Trust security model implementations (He et al., 2022). While enterprise environments, particularly in higher learning institutions, are deemed more trustworthy for Zero Trust authentication, challenges persist in strengthening the authentication of student records stored in the cloud and ensuring secure access for both staff and students (Abbott et al., 2020). Previous studies have highlighted the benefits of Zero Trust discipline in accounting, architecture management, and the implementation of Multi-Factor Authentication to protect critical applications and data assets (Alagappan et al., 2020). However, despite advancements in Zero Trust environments, there remains a need to provide cybersecurity defenders with more opportunities to detect novel threat actors and deploy response options swiftly to address sophisticated threats (US National Security Agency, 2021). In this study we shall do a comprehensive examination of the unique cybersecurity challenges faced by higher learning institutions and propose a zero-trust model solution to address these challenges. Additionally, incorporating insights from industry best practices and emerging technologies to enhance the effectiveness of proposed security strategies and ensure a proactive approach to cyber security defence.

1.2.1 Research Questions

1. What are the requirements for zero-trust on cyber-crimes for effective High Learning Institutions data records?
2. What challenges do information system administrators face in use of zero-trust authentication mechanism for effective higher Learning Institutional interaction?
3. How to evaluate the present zero-trust authentication weakness in administration of High Learning Institutions data records?

1.2.2 Aim of the Study

To develop a Zero Trust Security implementation model in Decentralized Network Resources for Institution of Higher Learning.

1.2.3 Objectives

1. To establish requirements for ZTS implementation in decentralized Network Resources for Institution of Higher Learning.
2. To design a ZTS implementation model in Decentralized Network Resources for Institution of Higher Learning.
3. To evaluate the model within different stakeholders in the Higher Learning Institutions like staff and students.

1.3 Scope of the Study

1.3.1. Time scope

The research is an assignment for a dissertation for a master's degree that lasts a period of one year. The time period will consider the field studies in Uganda and focus on ensuring security in Higher Learning Institutions. The study will strictly ZTS Implementation Consideration in Decentralized Network Resources for Institution of Higher Learning.

1.3.2 Technical scope

The technical scope considers the ZTS Implementation Consideration in Decentralized Network Resources for Institution of Higher Learning. The Zero Identity model will be designed to strengthen the trust in the network. Higher Learning institutions appreciate the Zero trust Multifactor authentication paradigm to overcome the challenges in records management among, staff and students in the institution. The staff and students will be liable to trust the zero-trust authentication for secure data records (notes, presentations, tests and examination scores). The decentralized network resources for Institution of Higher Learning for data management and the firewall to align availability of information in institutions. Limiting factors include, channels of data protection within people, workloads, devices and networks for an efficient communication.

1.3.3 Geographical scope

The Higher Education specifies the Higher Learning Institutions for exchange of notes, presentations, tests and examination results. The discussions between experts consider the insights of data records a management within staff and students. The zero-trust authentication paradigm ensures a complete security among the administrators.

1.4. Significance of the study

The student and staff records are expressly verified by the ZT Authentication. discrepancies in the explicit verification coverage of multifactor authentication across networks. Identity, endpoint, and network data that is readily available are used in the zero-trust paradigm. Regardless of the access protocols employed, access requests are authenticated by higher education establishments. Higher education institutions utilize ZT and Least Privilege Access (LPA) to restrict users' access to the environments, devices, and resources they require, hence making it more difficult for attackers to compromise critical systems and data. Access to attackers with fewer options to move laterally within the network beyond the inches is restricted due to wide spread privileges. The ZT shows that there have been ineffective communication breakdowns amongst Information System Security users. Zero Trust functions with an assumption that a breach occurred or was anticipated. In order to facilitate near real-time prevention, response, and remediation (error reduction), redundant security methods like ZTS detect anomalies and generate insights.

1.5 Justification

A report by Amy McIntosh of EdTech shows that cyberattacks in higher education institutions had resulted in the exposure of more than 1.3 million identities, education sector has by far been the most affected industry for malware attacks. And these modern attacks take advantage of organizations that don't have a Zero Trust architecture or strategy, partially due to the fact that many of these attacks are long and drawn out(Lee, 2021). The Zero Identity model will be designed to strengthen the trust in the network. Higher Learning institutions appreciate the Zero trust Multifactor authentication paradigm to overcome the challenges in records management among, staff and students in the institution. The discipline of ZT authentication touches channels of data protection within people, workloads, devices and networks for an efficient communication.

Chapter 2: LITERATURE REVIEW

This section describes the different aspects of ZT approaches and some of the models used to support successful implementation of zero trust in a decentralized environment. The literature helped us understand how institutions like Universities can implement zero trust technologies and our case university was Makerere University in Uganda.

2.1. Zero Trust

The Zero Trust model moves from securing the network perimeter to continuously verifying the trustworthiness of users, devices, and data access requests. (World Economic forum, 2022).It is the original ZT idea. While it can appear like a straightforward task, this calls for significant adjustments to both the implementation and utilization of security solutions as well asa shift in mindset. ZT is a principle-based model designed within a cybersecurity strategy that enforces a data-centric approach to continuously treat everything as an unknown – whether a human or a machine, to ensure trustworthy behavior (Elliott,2023). In its current form, the concept of ZT has mostly been applied to the information technology (IT) industry. It is difficult to maintain both IT and OT (operational technology) systems secure in the age of digitization since they overlap across enterprises. The idea of ZT must go beyond a restricted focus on theIT environment in order to defend the entire company against cyber risks and threats. Although some zero trust techniques (such network segmentation and multifactor authentication) can be adapted from the IT environment anddeployed in the OT context, OT systems were not designed with cybersecurity in mind (CISA, 2022).

According to World Economic forum, 2022, ZT is not a novel idea, but it has gained popularity in recent years for a variety of reasons. First, it is a key component of US President Barack Obama's Executive Order 14028, which aims to strengthen the country's cybersecurity position. As part of the actions taken to modernize approaches to cybersecurity, the executive order directs government entities to implement zero trust.(World Economic forum, 2022). The tremendous move to remote work and the rising acceptance of "bring your own device" (BYOD) practices, which highlights the importance for enterprises to secure their workforce and digital workplaces, are both contributing factors to the increased focus on zero trust. Gartner draws attention to this rise in awareness for some crucial components of zero trust. For instance, Zero Trust Network Access (ZTNA) is predicted to reach the so-called "plateau of productivity" over the next five

years, which is defined by widespread adoption and use. ZTNA's popularity surged by 230% between 2019 and 2020. The idea of zero trust has primarily been used in the field of information technology (IT) in its current form. In the age of digitization, it is challenging to keep both IT and OT (operational technology) systems secure as they intersect across businesses. In order to secure the entire enterprise from cyber risks and threats, the notion of zero trust must extend beyond a narrow emphasis on the IT environment. OT systems were not created with cybersecurity in mind, despite the fact that several zero trust methods.

Figure 2.1; Showing the guiding principles of zero trust (World Economic forum, 2022)

2.2 Zero Trust model

The ZT idea was first presented in a study titled "No More Chewy Centers, Introducing The Zero Trust Model Of Information Security" by Forrester Research analyst John Kindervag in 2010. The Report identifies typical issues with old network architectures that affect trust. The fact that some parts of the network are viewed as trustworthy by default presents a significant problem for network security. By connecting to the network, users may instantly access many different network regions and services. Since proper user authentication and access control can be difficult to establish, they are frequently disregarded and clients are assumed to be trustworthy. Building visibility and controls might be expensive. Another problem is that employees who work for the organization are instantly regarded as trustworthy individuals and are given automatic access to several network and service areas. The report emphasizes that insiders might be harmful as well and should never be trusted. The basic tenet of zero trust is thatall network traffic should be regarded as untrusted since it is impossible to establish confidence based on it.

This implies that access to resources must constantly be guarded and that access must only be permitted with legitimate access privileges. It is necessary to monitor and record all traffic. Professionals in network security are aware of these ideas, but putting them into action has proven difficult. By enhancing accuracy in network access choices and policy enforcement, Zero Trust offers concepts and approaches to make this a reality. With an emphasis on authentication and authorization, Zero Trust is emphasizing having the most precise access controls while still retaining usability and availability (Rose et al., 2020). Every person and every device is by default distrusted in architecture with zero trust. Before devices and users may access data, they must first authenticate and obtain authorization. In different studies pertaining to higher learning institutions, several zero trust models and frameworks have been proposed to enhance cybersecurity and mitigate risks associated with network breaches and data compromises. These models emphasize the principle of assuming zero trust in all network activities, requiring continuous verification and validation of users, devices, and applications. Here are some similar zero trust models discussed in the literature:

Forrester Zero Trust Model: Forrester Research introduced a comprehensive zero trust security framework that emphasizes continuous verification and strict access controls to protect against insider threats and external attackers (Forrester, 2020). This model advocates for the segmentation of networks and the implementation of granular access controls based on user identity, device posture, and contextual information.

NIST Zero Trust Architecture: The National Institute of Standards and Technology (NIST) developed a zero trust architecture that focuses on securing the modern enterprise network by assuming that threats exist both inside and outside the network perimeter (NIST, 2020). This model emphasizes the importance of micro-segmentation, identity management, and continuous monitoring to prevent lateral movement and unauthorized access.

Google BeyondCorp: Google's BeyondCorp model is a zero trust security approach that shifts the focus from network-based security to user and device-centric security (Kampanakis et al., 2014). BeyondCorp relies on strict access controls, device attestation, and context-based policies to enforce least privilege access and protect against advanced threats.

Cisco Zero Trust Model: Cisco's zero trust model emphasizes the integration of identity and access management (IAM), endpoint security, and network segmentation to enforce least privilege access and protect critical assets (Cisco, n.d.). This model advocates for the adoption of software-defined perimeters (SDPs) and continuous monitoring to detect and respond to security threats in real-time.

Palo Alto Networks Zero Trust Framework: Palo Alto Networks offers a zero-trust framework that combines network segmentation, least privilege access, and threat prevention capabilities to secure modern enterprise networks (Palo Alto Networks, n.d.). This framework emphasizes the importance of visibility, automation, and orchestration to streamline security operations and reduce risk exposure.

These zero trust models provide valuable insights and guidelines for higher learning institutions seeking to strengthen their cybersecurity posture and protect sensitive data from unauthorized access and exploitation.

2.2.1. Steps of Zero Trust Maturity

According to Sarkar et al., 2022, with increased infrastructure visibility and automated security controls, network managers will be able to better prevent threats and mitigate risks before significant harm can happen—far more than a typical perimeter security system can offer. Figure 2, below illustrates the simple steps to go through for an institution to achieve ZT maturity.

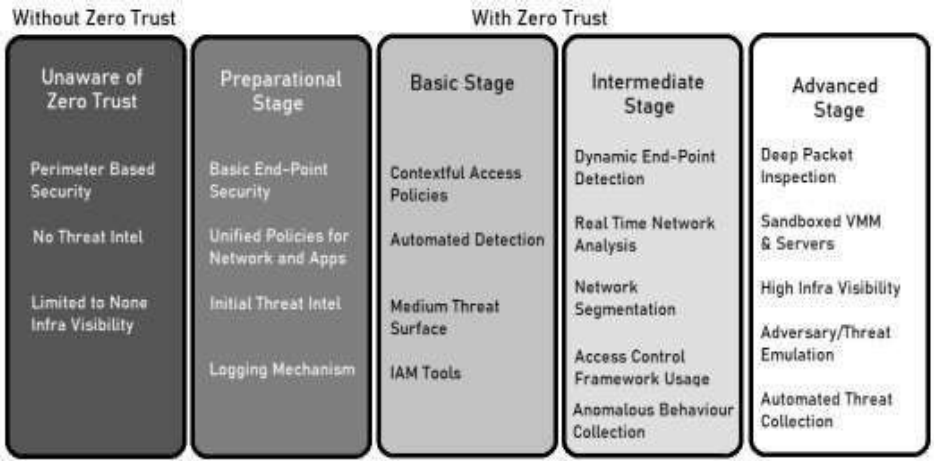

Figure 2.2; Showing the stages of Zero Trust (Sarkar et al., 2022)

2.2.2. The three pillars of Zero Trust

Zero Trust for the Workforce:

Zero Trust for the workforce focuses on securing user identities and ensuring that only authorized individuals gain access to network resources. This pillar emphasizes the importance of identity verification, authentication, and authorization mechanisms to validate the identity of users and devices attempting to

connect to the network. Organizations implement multi-factor authentication (MFA), biometric authentication, and identity federation to strengthen identity verification processes (NIST, 2020). Workers, contractors, partners, and suppliers are among the individuals who access work apps on their own or company-managed devices. This pillar ensures that only authorized users and secure devices can access apps, no matter where they are. Moreover, Zero Trust for the workforce involves continuous monitoring and analysis of user behavior and access patterns to detect anomalous activities indicative of potential security threats. User and entity behavior analytics (UEBA) tools and security information and event management (SIEM) systems play a vital role in identifying suspicious behavior and enforcing least privilege access based on contextual information (Forrester, 2020). To further enhance security, organizations employ access controls and role-based access policies to restrict user privileges based on their job roles and responsibilities. Zero Trust for the workforce also emphasizes the need for regular user training and awareness programs to educate employees about cybersecurity best practices and the importance of maintaining security hygiene (Google Cloud Platform Blog, 2014).

Zero Trust for Workloads:

Zero Trust for workloads focuses on securing applications, data, and workloads hosted in cloud environments, data centers, and hybrid IT environments. This pillar emphasizes the importance of workload segmentation, encryption, and micro-segmentation to minimize the attack surface and prevent lateral movement within the network (NIST, 2020). This pillar focuses on safe access when an application's database is accessed via an API, microservice, or container. Organizations implement network segmentation and micro-segmentation techniques to isolate workloads and enforce strict access controls based on workload identity, attributes, and communication patterns. Additionally, encryption technologies such as data-at-rest encryption and data-in-transit encryption are employed to protect sensitive data and communications (Forrester, 2020). Furthermore, Zero Trust for workloads involves continuous vulnerability assessment and patch management to identify and remediate security vulnerabilities in software and applications. Automated configuration management tools and container security solutions help ensure that workloads adhere to security policies and compliance requirements (Google Cloud Platform Blog, 2014).

Zero Trust for the Workplace:

Zero Trust for the workplace focuses on securing devices, networks, and physical spaces within the organization's premises. This pillar emphasizes the importance of device verification, network segmentation, and access control mechanisms to protect against physical and cyber threats (NIST, 2020). Organizations implement endpoint security solutions, network access control (NAC) systems, and

physical access controls to verify the security posture of devices and restrict network access based on device health and compliance status. Additionally, network segmentation techniques such as virtual LANs (VLANs) and software-defined perimeters (SDPs) help isolate critical assets and limit lateral movement within the network (Forrester, 2020).

Moreover, Zero Trust for the workplace involves surveillance and monitoring of physical spaces through the use of video surveillance cameras, access logs, and biometric authentication systems. Organizations also conduct regular security audits and risk assessments to identify vulnerabilities and strengthen security controls (Google Cloud Platform Blog, 2014). Zero Trust principles applied to the workforce, workloads, and workplace provide a comprehensive framework for securing digital assets and mitigating cybersecurity risks in modern organizations. By implementing robust identity verification, access controls, and continuous monitoring mechanisms, organizations can strengthen their security posture and adapt to evolving threat landscapes.

2.3. Application of Zero Trust identity

Due to the inherent complexity of Zero Trust, no single vendor or service currently encompasses its entire spectrum of capabilities and elements. Consequently, institutions pursuing Zero Trust implementation must navigate a multi-vendor landscape, necessitating careful partnerships with various providers. To navigate this complexity effectively, crafting a realistic and practical roadmap becomes crucial. Such a roadmap empowers institutions to systematically identify, assess, and select the most suitable vendors and specific technologies tailored to their unique needs and context(Gartner,2023). The recruitment of institute (business) and IT stakeholders in the development of the roadmap will be necessary for the Zero Trust implementation, which will also result in an avalanche of technological and organizational change. The institution must atthe very least include the following individuals when identifying the key players who are essential to the institute's Zero Trust approach. Board members of the institute, who frequently make the final decisions, as well as business and IT executives, who will approve your budget. ii. The enterprise architects and application owners of the institute. (Garbis & Chapman, 2021; Lowdermilk & Sethumadhavan, 2021). The IT operations team of the university (who will oversee the infrastructure you are creating). (Liu et al., 2022) discusses a data driven zero trust algorithm, The access object is the primary protected resource under its ZT architecture, andfor the protected resources—which may also include but are not limited to important information infrastructure like business applications,

service interfaces, operation functions, and data—a protection surface is developed. The study explains trust evaluation as the core practice of ZT architecture to build trust from scratch. -rough the trust evaluation engine, the ability of identity- based trust evaluation can be realized. The study incorporates the normal cloud theory into the measurement of user behavior trust despite the fact that the boundary of user behavior trust level is hazy and user behavior is extremely variable. The uncertain translation from a qualitative concept to a quantitative representation is realizable using standard cloud theory.

2.4. The Zero Trust architecture

Traditionally, "perimeter security" reigned, operating on the principle of "trust but verify." Once inside the castle walls (the network), users who'd cleared security checkpoints enjoyed free movement. External threats were the primary concern. However, the Zero-Trust model shatters this trust zone, replacing it with "verify without trust" – every access attempt, internal or external, undergoes rigorous and continuous scrutiny. In essence, Zero-Trust Architecture (ZTA) embodies a fundamental shift: recognizing that threats can lurk anywhere within the network, not just outside. This requires a coordinated set of design principles built on continuous authentication, authorization, and access control, dismantling the illusion of a secure inner sanctum(NIST,2020) This proposed network architecture embraces a philosophy of perpetual skepticism. Unlike traditional models that extend trust once entities pass initial scrutiny, here, near-constant verification and analysis become the lifeblood of the system. Every network node, service, application, and user group exist under a microscope of continual examination. Access to resources, be it databases, other nodes, servers, or even policies, is granted only after rigorous verification and with a strict time-bound trust window. Upon expiry, elements must re-enter the verification cycle, ensuring continuous vigilance against both internal and external threats(Forster,2020). Internal applications are exposed outside of the network perimeter in a zero trust architecture, often known as a perimeter less network design. As opposed to conventional network designs, which prioritize network edge protection, Zero Trust prioritizes resource protection. Strongauthentication, encryption, and unified policy enforcement are used to implement protection. Perimeter becomes application-specific with zero trust. Zero Trust Architecture aims to give apps from any network a uniform user experience while also safeguarding the applications. (Goerlich, Wolfgang, Wendy Nather, Pham, Thursday, 2020.) (Gartner, 2019) Architecture and Solutions for Zero Trust.

2.5. Zero Trust Identity in Higher institutions.

In order to shift from a network-oriented, perimeter-based security approach to one that is focused on continuous trust verification, Zero Trust is a conceptual and architectural framework to be applied (Lowdermilk & Sethumadhavan, 2021). Built on the fundamental concept of Zero Trust, its establishment may appear straightforward at first glance. However, adopting this approach necessitates a shift in perspective and significant alterations to the implementation and utilization of security measures. Crafting a comprehensive roadmap becomes imperative to delineate the key workstreams and responsibilities essential for the successful implementation of a Zero Trust approach (N. Forster & A. Askari,2020).The delivery timetable, financial needs, and particular business and security advantages related to investing in Zero Trust can all be evaluated by administrators. Before formalization, institutions should assess the strategy and conduct the following actions:

1. Identify their overarching Zero Trust strategy.
2. Describe the seven fundamental tenets or elements of Zero Trust within their institutional context.
3. Specify the essential institutional capabilities required to fulfill all requirements.
4. Engage both institutional and IT stakeholders in the roadmap development.
5. Recognizing connections with other security, IT, and institutional endeavors is crucial.

In terms of data security, institutions need to guarantee the capacity to categorize, store, archive, or remove data in alignment with established policies (Garbis & Chapman, 2021b; Horne & Nair, 2021). Given that a singular vendor or organization cannot offer all the functionalities and elements of the Zero Trust model, collaboration with multiple vendors becomes imperative. Creating a practical roadmap will enable institutions to identify and evaluate suitable vendors and technologies. Engaging both institutional and IT stakeholders in the roadmap development is essential, involving the institute's board members, business and IT executives, enterprise architects, application owners, and IT operations team (Garbis & Chapman, 2021a; Lowdermilk & Sethumadhavan, 2021). Understanding stakeholder concerns and addressing them is vital. Institutions should communicate their vision clearly, listen to feedback, and ensure understanding among stakeholders. Interdependencies with other security, IT, and business projects should be identified. Zero Trust efforts should incorporate existing security, IT, and business initiatives such as cloud migrations or collaborations with new partners (Greenwood, 2021; Wylde, 2021). As additional stakeholders are recruited, related roadmaps should be integrated into the Zero Trust endeavor. It is crucial to map

and communicate project dependencies, considering existing requirements. For instance, overly granular micro-segmentation may disrupt network functions and hinder IT operations (Sheikh et al., 2021). Identifying the starting point for Zero Trust implementation in higher learning institutions involves assessing their current maturity level and the desired future state for each phase. This helps in focusing on specific initiatives and tasks. For example, if an institution already has mature identity and access management capabilities, they may begin with less mature areas like cloud workload protection. Building a successful Zero Trust roadmap requires pinpointing your institute's current security readiness, navigating existing projects, leveraging internal expertise, and charting a clear course for future maturity with defined timeframes(NIST,2020).

2.6. Network Resources

There is no central authority in the form of a server that can audit requests and manage information in a decentralized peer-to-peer network. Instead, depending on the situation, every user, or node as they are commonly known in peer-to-peer networks, act as both a client and a server(Fagerlund, 2021). As a result, when a new node enters the network and starts producing more network requests, there is no need for more server resources to fulfill those requests because the new node also supplies the network with additional resources(Fagerlund, 2021). According to Fagerlund 2021, decentralized P2P networks can scale to the number of users due to this type of self-sufficiency without the addition of more specialized resources. There is no reliable central authority that a client can rely on because each node is free to establish its own rules. No one in the network can be trusted because all calculations and information managementare instead handled by the client's peers. When users of a file sharing program want to exchange resources with one another without the knowledge or interference of centralized authority, the network type has historically been particularly a popular one. In higher learning institutions, network resources play a crucial role in supporting various academic and administrative activities, including research, collaboration, and communication. To effectively manage and secure these network resources, institutions often rely on a variety of network tools and technologies. Below are some of the key network tools useful for enhancing network performance, security, and management in higher learning institutions:

Network Monitoring Tools: Network monitoring tools such as SolarWinds Network Performance Monitor (NPM) and Nagios provide real-time visibility into network performance metrics, including bandwidth usage, latency, and packet loss (SolarWinds, n.d.; Nagios, n.d.). These tools help administrators identify and troubleshoot network issues promptly, ensuring optimal performance and reliability for academic and administrative applications.

Intrusion Detection and Prevention Systems (IDPS): IDPS solutions like Snort and Suricata help detect and mitigate security threats and malicious activities on the network (Snort, n.d.; Suricata, n.d.). By analyzing network traffic patterns and signatures, IDPS tools can identify and block suspicious behavior, protecting sensitive data and critical infrastructure from cyberattacks.

Network Access Control (NAC) Systems: NAC systems such as Cisco Identity Services Engine (ISE) and Aruba ClearPass provide centralized authentication and authorization for devices connecting to the network (Cisco, n.d.; Aruba, n.d.). These systems enforce security policies based on user identity, device posture, and contextual information, ensuring compliance with institutional security standards and regulations.

Virtual Private Network (VPN) Solutions: VPN solutions like OpenVPN and Cisco AnyConnect enable secure remote access to institutional network resources for faculty, staff, and students (OpenVPN, n.d.; Cisco, n.d.). By encrypting network traffic and establishing secure tunnels over public networks, VPNs protect sensitive data and ensure privacy and confidentiality for remote users.

Network Configuration Management Tools: Network configuration management tools such as ManageEngine OpManager and SolarWinds Network Configuration Manager (NCM) streamline the configuration and provisioning of network devices (ManageEngine, n.d.; SolarWinds, n.d.). These tools automate routine tasks such as device backups, firmware updates, and configuration changes, reducing the risk of human error and ensuring consistency across the network infrastructure. These network tools provide essential capabilities for managing and securing network resources in higher learning institutions, supporting the diverse needs of academic and administrative stakeholders. By leveraging these tools effectively, institutions can enhance network performance, mitigate security risks, and optimize resource utilization to support teaching, learning, and research activities.

2.6.1 Network Security

It is crucial to realize that the network itself has an identity within the Zero Trust framework, depending on whether it is trusted and what time of day data is accessible. In addition to technology relating to grouping host servers, data connections, interfaces between hosts, network segmentation, intrusion detection, and cryptography of host-to-host flows (such as SSL, VPNs), the network component can also include more esoteric ideas like "time of day" and the proximity of multi-factor mechanisms to the network.. Depending on where the network traffic is coming from, an organization could have various access restrictions. An organization might have a policy that prohibits access to sensitive data from a coffee shop on a public network. Security engineers can

partition critical on-premises resources into their own groups by using their knowledge of endpoint locations, and they can only grant access to individuals and roles that are both acceptable and allowed(Sarkar et al., 2022).

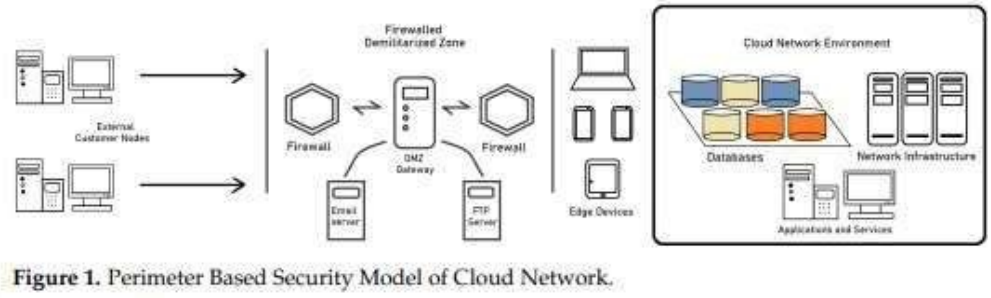

Figure 1. Perimeter Based Security Model of Cloud Network.

Figure 2.3; Showing a perimeter Based Security Model of Cloud Network(Sarkar et al., 2022)

2.7. Challenges with Network-based Security

Traditional network-based security has some serious flaws nowadays(Baraković & Skorin- Kapov, 2013). The networks are under strain because to the rise in digital goods and services as more devices are connected to the network, such as smart gadgets and cloud services ((Baraković & Skorin-Kapov, 2013). A network can now be exposed to a vastly increased variety of threats, which has further complicated the task of defending it from harm(Borky & Bradley, 2019). The fact that many organizations do not adequately monitor their networks is a cause for growing worry. "Network security is the same as Murphy's law in the sense that, if something can go wrong, it will go wrong," is a common saying, additionally, it suggests that the entire security level is determined by the security architecture's weakest link(Yaacoub et al., 2022)

As a result, it is simple for hackers to penetrate software or hardware with insufficient security and get access to the organization's internal network without authorization(Hansen, 2022). Bring your own device (BYOD), distant offices, increasingly sophisticated assaults, and a lack of trust are the four main causes of network-based security's growing weaknesses. Verification happens less frequently than trust, yet trust is commonly overdone. Without sufficient verification, the trust-giving generosity of organizations leads to failures in the trust model and, further, to a significant vulnerability in network security(John Kindervag, 2010).Increased digital identity creation and automated malicious threats have exposed vulnerabilities in identifying individuals through IP addresses (Dobos, 2020). The dynamic nature of IP addresses poses challenges in accurately determining the true identity and authorization of users or devices (Dobos, 2020). The concept of

network-based security, which relied on devices within the physical office perimeter,is no longer sufficient due to the advent of cloud services and the surge in remote work,particularly during the COVID-19 pandemic (Deshpande, 2021; Buck et al., 2021; Teerakanok, 2021; Chen et al., 2019; Ward & Beyer, 2014). Remote work has blurred the boundaries of the network perimeter, making it difficult to protect all internal assets (Ward & Beyer, 2014). Bring Your Own Device (BYOD) policies add complexity to security as devices that are not closely monitored by the organization can gain access to internal networks and resources (Chen et al., 2019). Sophisticated attacks can exploit legitimate user access points, undermining the effectiveness of traditional control measures (Kindervag, 2010). Traditional security solutions rely on static rules, which are insufficient to counter dynamic and advanced threats (Buck et al., 2021). As a result, these solutions are no longer considered fully effective in ensuring network security (Kindervag, 2010). While Zero Trust architectures offer advantages, they also present challenges. Transitioning from traditional network-based security to a Zero Trust approach carries risks and requires significant changes in IT infrastructure, processes, and user training (Buck et al., 2021; Daley, 2022). This transformation can be time-consuming and costly (Buck etal., 2021; Daley, 2022). Determining and defining trust levels for users and devices pose challenges, as overly strict or lenient criteria can disrupt workflows or compromise data protection (Teerakanok et al., 2021). Minimizing disruptions to end-users during the implementation phase is crucial for a seamless transition to Zero Trust, but it can be challenging to achieve (Teerakanok et al., 2021). Organizations often introduce restrictions in existing systems while implementing new Zero Trust principles, and eventually replace old processes with new Zero Trust solutions, which can disrupt workflows and negatively impact user experience (Teerakanok et al., 2021; Chen et al., 2019). Limited knowledge and uncertainties surrounding the implementation of Zero Trust further complicate the assessment of its disadvantages compared to its benefits (Buck et al., 2021).

In summary, the increase in digital identity creation and automated threats has exposed vulnerabilities in relying on IP addresses for identification. The evolving nature of remote work and BYOD policies has challenged the traditional network-based security paradigm. Sophisticated attacks and the limitations of static control measures necessitate the adoption of Zero Trust architectures. However, transitioning to a Zero Trust approach involves risks, costs, and complexities in defining trust levels and minimizing disruptions to end-users. Limitedknowledge of implementation challenges adds to the difficulty of accurately assessing the disadvantages of Zero Trust compared to its benefits. Currently, the basic principles of Zero Trust Architectures (ZTAs)

have been established, but achieving the standard of ZTA with various technologies remains a challenging problem. Access control, identity authentication, and trust assessment in ZTA are still in the early stages of research. A hot topic for future research is how to utilize these technologies to enhance the security and practicality of ZTA. Once a new ZTA is proposed, the challenge lies in applying it to real enterprise network environments. In the realm of identity authentication, single-factor authentication is vulnerable because it relies on a single unique factor for authentication. If the unique password or biometrics are stolen, the authentication collapses entirely. Multifactor authentication mitigates this concern by enhancing the limitations of single-factor authentication, substantially diminishing the risk of network attacks. Even in scenarios where an attacker manages to intercept password information, the complexity of obtaining authorization for the second or third factor is notably heightened. Furthermore, continuous authentication changes the traditional approach of granting access rights after a one-time authentication. It continuously verifies the user's identity and grants access rights throughout the session, thereby reducing the security risks posed by attackers during the session and enhancing system security. The evolution from single-factor to multifactor authentication and from one-time authentication to continuous authentication signifies the ongoing improvement of security measures.

As cyber threats escalate, Zero Trust architectures are turning to sophisticated authentication methods like multi-factor and continuous authentication for enhanced security. These diverse protocols, encompassing certificates, encrypted, and non-encrypted variants, present a spectrum of security versus resource consumption trade-offs. Striking the optimal balance – minimizing resource drain while maximizing system security – lies at the heart of future identity authentication within Zero Trust frameworks. This evolution reflects the alarming rise in the number and sophistication of cyberattacks targeting enterprises, a trend projected to continue. This trend will further complicate the computing environment. Therefore, the access control system needs to be dynamically adjusted, and risk assessment should be integrated into the access control process. Access control decisions will consider various factors, such as the trust level of users and devices, as well as the situational environment of users and wireless communications. In summary, although the basic principles of ZTA have been established, there are still challenges in aligning various technologies with these principles. Future research focuses on utilizing technologies to enhance the security and practicality of ZTA, as well as applying ZTA to real enterprise network environments. Multifactor and continuous authentication methods play a significant role in improving security within ZTA. Additionally, finding a balance between security and resource consumption in identity authentication

protocols is crucial. The increasing complexity of security attacks and computing environments necessitates dynamic access control systems with integrated risk assessment.

2.8 Benefits of Zero trust implementation in Institutions.

In today's interconnected digital landscape, institutions face an ever-evolving cybersecurity threat that can compromise sensitive data, disrupt operations, and damage reputation. Traditional security measures, such as perimeter-based defenses, are proving inadequate against sophisticated attacks. In response, institutions are increasingly turning to a Zero Trust security model to mitigate risks and fortify their defenses. This paper explores the benefits of implementing Zero Trust in institutions, emphasizes its role in enhancing security and resilience. One of the primary benefits of Zero Trust implementation is its ability to mitigate insider threats. Insider threats, whether malicious or unintentional, pose significant risks to institutional security. By adopting a Zero Trust approach, institutions scrutinize and authenticate every user, device, and transaction, regardless of their location within the network. This granular level of verification minimizes the likelihood of unauthorized access and reduces the attack surface, thereby enhancing protection against insider threats (Lindstrom, 2020). Furthermore, Zero Trust emphasizes the principle of least privilege, ensuring that users only have access to the resources necessary for their roles, limiting the potential damage caused by compromised credentials or malicious insiders. Institutions operate in dynamic environments characterized by evolving business requirements, technological advancements, and emerging threats. Zero Trust's adaptive nature aligns well with these dynamics, offering flexibility and scalability to accommodate changing needs. Unlike traditional security models that rely heavily on static perimeter defenses, Zero Trust continuously assesses and adapts security measures based on real-time data and contextual information (Weinschenk, 2019). This adaptive approach enables institutions to swiftly respond to emerging threats, adjust access privileges based on evolving user roles, and seamlessly integrate new technologies into the security framework.

Zero Trust implementation enhances visibility into network activities and facilitates centralized control over security policies. By implementing robust identity and access management (IAM) solutions, institutions gain comprehensive insights into user behavior, device posture, and data transactions across the network (Palo Alto Networks, 2021). This visibility enables proactive threat detection and incident response, allowing security teams to swiftly identify and mitigate potential risks. Moreover, Zero Trust empowers institutions to enforce consistent security policies across diverse environments, including on-premises, cloud, and hybrid infrastructures, thereby reducing

complexity and ensuring compliance with regulatory requirements (Forrester, 2020). Institutions face a myriad of threats, ranging from ransomware attacks to natural disasters, which can disrupt operations and jeopardize continuity. Zero Trust implementation enhances resilience by adopting a holistic approach to security that encompasses prevention, detection, and response capabilities. By leveraging advanced security controls, such as micro-segmentation, encryption, and multifactor authentication, institutions can minimize the impact of security incidents and maintain business continuity (Cybersecurity & Infrastructure Security Agency, 2021). Additionally, Zero Trust's focus on continuous monitoring and risk assessment enables institutions to identify vulnerabilities proactively and implement timely remediation measures, thereby reducing the likelihood and severity of disruptions. Institutions are under constant pressure to safeguard sensitive data, preserve business continuity, and mitigate cybersecurity risks. Zero Trust offers a paradigm shift in security strategy, emphasizing the importance of continuous verification, adaptive controls, and granular access policies. By adopting a Zero Trust approach, institutions can enhance protection against insider threats, adapt to dynamic environments, improve visibility and control, and enhance resilience in the face of evolving threats. As cybersecurity threats continue to evolve, institutions must embrace innovative approaches like Zero Trust to safeguard their assets and maintain trust in an increasingly interconnected world.

2.9 Review of Related works

(Mandal et al., 2021) produced a policy that uses access control, based on the transport access control (TAC) layer to extract and analyze the TCP packets of incoming traffic, a hypertext transfer protocol (HTTP) was also used as the application layer protocol. In the policy Individual untrusted IP addresses are verifed explicitly by the zero-trust network at the time of establishing a session with the cloud resources. The existing identity access management (IDM), such as Amazon Web Services (AWS) or Microsoft Web Directory cloud services, takes the control of the authentication of IP addresses ARP queries from verified hosts include their matching IP addresses. After receiving the ARP answers, the network parameters that match the IP addresses were put in the ARP table. The ARP protocol also does MAC address retrieval. Instead of inspecting the full TCP packet, the explicit TCP header is checked for the port numberand destination IP address, which minimizes the time required to examine each individual TCP packet. It now keeps the network's high bandwidth and low latency. Our access control policy should be put into effect at a virtual security gateway where authenticated IP addresses are sent through. Mandal et al.'s access control policy offers a robust framework for securing network traffic and enabling secure access to cloud resources in a zero-trust environment. By leveraging the TAC layer and integrating with existing identity access management systems, the model provides a foundation for

enhancing network security and mitigating potential threats. However, further research and refinement are needed to address scalability, performance, and authentication challenges, ensuring seamless adoption and effectiveness in higher learning institutions. Mandal et al. (2021) introduced a novel access control policy leveraging the Transport Access Control (TAC) layer to extract and analyze TCP packets from incoming traffic. Their model primarily focuses on utilizing HTTP as the application layer protocol for establishing TCP connections with cloud servers/resources, ensuring secure access in a zero-trust network environment. In this review, we delve into the key components and implementation strategies outlined by Mandal et al., highlighting the strengths and potential areas for improvement:

Transport Access Control (TAC) Layer: Mandal et al. emphasize the utilization of the TAC layer to extract and scrutinize TCP packets, enabling fine-grained control over network traffic. This approach enhances security by scrutinizing packets at the transport layer, where critical information such as source, destination, and session details are available. **Application Layer Protocol (HTTP):** The model leverages HTTP as the application layer protocol for initiating TCP connections with cloud resources. This choice enables seamless integration with existing cloud services and facilitates secure communication between clients and servers. **Identity Access Management (IDM):** Existing identity access management systems, such as Amazon Web Services (AWS) or Microsoft Web Directory, play a crucial role in the authentication of IP addresses. IDM verifies untrusted IP addresses and grants explicit trust to authenticated hosts, enabling the creation of TCP sessions for accessing cloud services securely. A**RP Queries and IP Address Credentials:** Credentialed hosts send IP addresses associated with ARP queries, allowing for dynamic verification and authentication of hosts. This dynamic approach ensures that only authorized hosts gain access to cloud resources, mitigating the risk of unauthorized access and potential security breaches. The model implementation begins with the interception of incoming traffic at the TAC layer, where TCP packets are extracted and analyzed in real-time. HTTP is employed as the primary application layer protocol for establishing TCP connections with cloud resources, ensuring compatibility and interoperability with existing cloud services.Identity access management systems, such as AWS or Microsoft Web Directory, are integrated to authenticate IP addresses and validate hosts before granting access to cloud services. Dynamic verification mechanisms, including ARP queries and IP address credentials, are utilized to dynamically authenticate hosts and establish secure TCP sessions based on trust levels. **Strengths:** Seamless Integration with Existing Cloud Services. Fine-Grained Control Over Network Traffic. Dynamic Authentication Mechanisms for Host Verification. **Areas for Improvement:** Scalability and Performance Optimization. Enhanced Support for Multi-factor Authentication. Comprehensive Logging and Auditing Mechanisms

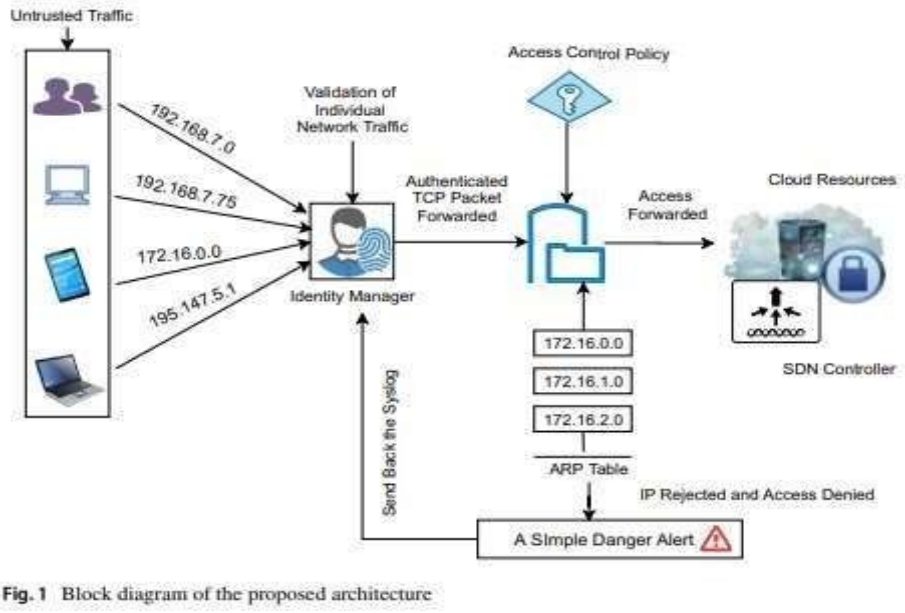

Fig. 1 Block diagram of the proposed architecture

Figure 2.4 ; (Mandal et al., 2021)

A zero trust cloud data center network proposed by (Eidle et al., 2017) used identity management along with automated threat response and packet-based authentication for establishing trust. The model generated eight distinct networks trust levels and was able to dynamically manage them. The table below shows the different levels

Level 7	Least restrictive; by default, forward all traffic on trusted and untrusted interfaces (note: requires a configured route table or NAT table to operate properly in some cases)
Level 6	Customer Policy, Group Level
Level 5	Customer Policy, Group Level
Level 4	Customer Policy, Group Level
Level 3	Customer Policy, Group Level
Level 2	System Wide policy defined by admin only
Level 1	System Wide policy defined by admin only
Level 0	Most restrictive, System Wide policy; blocks all traffic on trusted and untrusted interfaces

Users deemed trustworthy receive identity tokens, which Gateway One then inserts. In contrast, untrusted users do not receive such authentication tokens. The authentication of these identity tokens occurs at the initiation of a TCP connection request, preceding the completion of the traditional 3-way Ethernet handshake and the establishment of sessions with cloud or network resources. This early authentication process establishes a clear and explicit trust. Each unique entity seeking access to a network resource, with a pre-defined static identity on the gateway, generates its own token.

These entities typically represent users or devices. (Eidle et al., 2017). Unwanted network traffic is outright rejected, and any endeavor by a potential attacker to fingerprint the system results in no response from the transport layer or lower-level resources, which are typically users or devices (Eidle et al., 2017). (Decusatis et al., 2016) employed tokens embedded in the initial Transmission Control Protocol (TCP) packet to authenticate and verify user identity as part of their methodology. This approach showcased the capability of their network model to safeguard against DDoS attacks, identity spoofing, and network fingerprinting by adversaries across diverse scenarios. These scenarios included enterprise-class servers, cloud computing data centers, and a campus-based network connecting multiple physical locations. The method of first-packet authentication with tokens was subsequently extended to address the specific needs of geographically dispersed cloud networks in higher education.

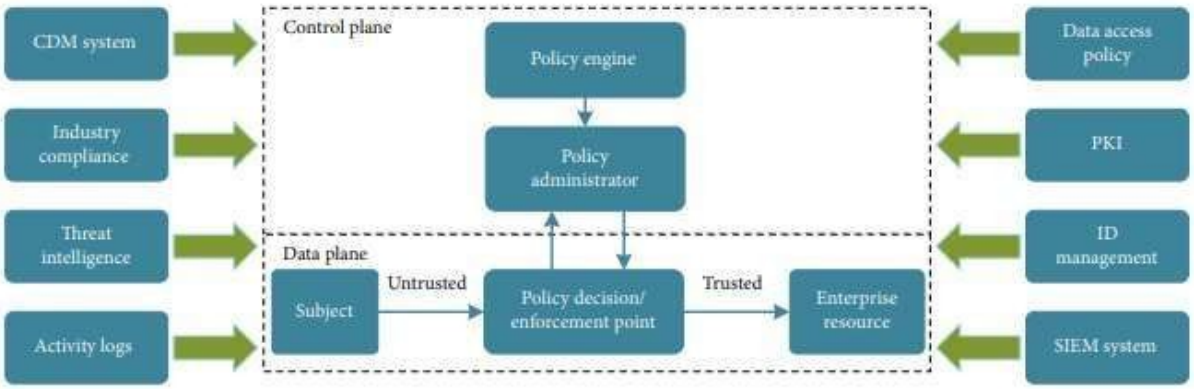

Figure 2.5 Showing the implementation of the Zero Trust Architecture (He et al., 2022)

In 2021, da Silva et al. proposed a smart home system using Zero Trust principles and continuous authentication based on user behavior. This system utilizes edge computing to identify and block unauthorized access and unreliable service providers, enhancing overall security. Continuous identity authentication within the Zero Trust framework aims to consistently validate the legitimacy of the user. However, its precision remains uncertain as it has not undergone testing in a real-world setting and has not assessed the impacts of concurrency or latency. Hatakeyama et al. (2021) introduced a groundbreaking access control model for Zero Trust networks that breaks free from traditional assumptions of trust based on factors like source networks. Instead, this dynamic approach meticulously evaluates each access request on its own merits. By scrutinizing the requester's identity, purpose, and context, the system determines whether to grant access, ensuring a continuous assessment of trustworthiness rather than relying on pre-established trust zones. It is

unable to run the authorization server or the identifier that is used when the context cannot be shared, and it does not standardize the format or semantics of the context in ZTF. The same year, Mandal et al. (2021) established a MAC spoofing defense mechanism in the SDN framework of the cloud architecture to support the COVID-19-driven work-from-home approach, thereby proposing a cloud-based zero trust access control strategy. When the enterprise structure's access control strategy needs to be modified, it performs more accurately by looking at the source TCP/IP traffic and the MAC addresses that go along with it, gathering specific network traffic from untrusted zones. Its AI-based models help lower thresholds and normalize traffic when the network is growing rapidly.

However, facing the security challenges posed by sophisticated attackers, ensuring optimal security while reducing access thresholds and utilizing cloud resources becomes a complex task. Additionally, the time-intensive process of analyzing network traffic and addressing compromised user accounts remains unresolved. Yang et al. (2022) presented an innovative solution—a dynamic access control model incorporating blockchain and short-term tokens. This model integrates user trust assessment into the role-based access control (RBAC) framework, incorporating a deep learning-based algorithm for detecting abnormal user behavior. The system dynamically assesses user actions, updates trust levels, and adjusts access rights based on the continuous modification of short-term tokens. However, it shares common challenges with RBAC, such as difficulties in establishing an initial role structure and a lack of flexibility in adapting to evolving IT technologies.In a related study, Chuan et al. (2020) outlined seven factors to evaluate zero trust, providing a practical method. These factors include assessing vulnerabilities in the operating system and network, identifying weak passwords, scrutinizing high-risk ports, safeguarding sensitive information, and monitoring accounts and passwords. The proposed method encompasses essential procedures such as host vulnerability detection, password checks, website evaluations, configuration assessments, security reinforcement, defense against brute force attacks, and micro-isolation control. (Yao et al., 2020) introduced a dynamic system for access control and authorization based on the Zero Trust (ZT) security architecture. This system, leveraging the Trusted Behavior Access Control (TBAC) model, creates a user profile and assesses user trust through behavior analysis. For flexible and precise access control, the system employs real-time hierarchical control across different situations.

Table 1; Summary of related work

Publication Year	Authors	Tittle	Main Contribution
2021	da Silva et al.	Zero Trust Access Control with Context Awareness and Behavior-Based Continuous Authentication for Smart Homes	Proposed a zero-aware smart home system with continuous identity authentication, powered by edge computing, for access control in smart homes.
2021	Hatakeyama et al.	A New Access Control Model for Zero Trust Networks	Introduced an access control model for zero trust networks that does not assume trusted properties and evaluates the worthiness of each access request.
2020	Chuan T et al.	Method for Implementing the Concept of Zero Trust	Outlined the seven evaluation components for the zero trust assessment, which included the necessary steps, vulnerabilities in the operating system and network security, weak passwords, high-risk ports, accounts, and the protection of sensitive information.
2020	Yao et al.	Dynamic Access Control and Authorization System based on Zero Trust	Proposeda system for dynamic access control that generates user portraits and trust by utilizing the TBAC model and user behavior. Real-time hierarchical control was put into place for granular authorization and access control.
2021	Mandal et al.	Cloud-Based Zero Trust Access Control Strategy	Proposed a cloud-based zero trust access control method for the SDN framework in the cloud architecture that included a MAC spoofing defense mechanism. decreased thresholds and normalized traffic using AI-based models.

Chapter 3: RESEARCH METHODOLOGY

This section describes the main methods and research design we followed in order to achieve the objectives of the study. The study mainly based on literature and also had a discussion with the network administrators within the institution. Through literature we were able to understand the challenges associated with the non-zero trust networks and also the problems the users connectedon the network may face.

3.1. Research Design

This section describes the methods and techniques applied to conduct the study. This allowed us understand the suitable methods for this study. The research design chosen allowed us achieve the objectives of the study. In the research design we came up with a plan for collecting and analyzing data that will help us come up with recommendation and evidence about the use of Zero trust models within the University.

3.1.1 Case study methodology

This research used a case study methodology, where Makerere University was used to do the evaluation of the challenge institutions face while applying zero trust models. The Case Study as a qualitative design helped in exploring the in depth of the processes within the University network, in this we worked with the network administrators, students and system administrators to find-out the challenges with zero trust implementations. In the institutions there were decentralized networks, where resources have been distributed across various locations and managed by different departments or entities. In this study we performed a comprehensive understanding of the network architecture, user behaviors, and potential threats. A case study methodology offered a structured approach to analyze and document the implementation of Zero Trust security in decentralized networks within institutions of higher learning. The figure below shows the steps followed while applying the case study methodology.

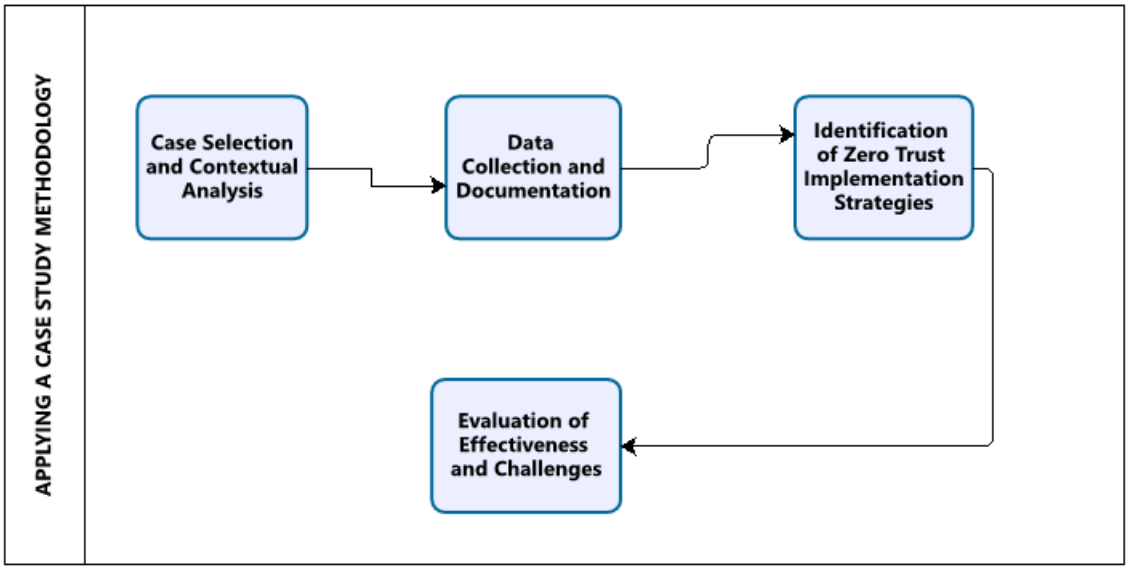

Figure 3.1 ; showing the follow of the case study methodology applied.

1. Case Selection and Contextual Analysis

The study started with selecting an appropriate institution of higher learning with a decentralized network infrastructure as the subject of investigation. The selected institution has a range of departments, academic disciplines, and administrative units to capture the complexity of decentralized networks. We then gathered information about the institution's network architecture, existing security measures, compliance requirements, and specific challenges related to decentralized operations. In the selection of the institution and network environment we considered the following factors.

Size and Complexity of the Institution: The University has large number of departments and a diverse network infrastructure which is distributed within the university environment.

Technological Maturity: There is a high technological maturity within the University where they embrace learning through hybrid, online and in-person studies, this helped us understand the security measures in place and areas of improvement.

Geographical Distribution: The University has multiple campuses or distributed networks hence presents unique challenges in terms of network segmentation and access control.

Previous Security Incidents: Any history of security incidents or breaches within the institution guides the selection of facilities and environments requiring heightened security measures. These factors justify the selection by ensuring that the chosen facilities and environments represent a diverse range of network infrastructures and security challenges commonly encountered in higher learning institutions.

2. Data Collection and Documentation

Qualitative data collection methods were used like interviews and questionnaires. In the interview we used purposive sampling where we discussed with a few people in the network department of the University to ask questions around zero trust implementation. Majority of them were aware of the multifactor authentication but did not have ideas on how to implement zero trust models in the institutions. We also issued out questionnaires to 15 people within the University and this enabled in the collection data that helped us get recommendations on how best a zero-trust model can be implemented within the University. Data collection methods like interviews with key stakeholders such as IT administrators, network engineers, faculty members, and students was done to gain insights into their experiences, perceptions, and expectations regarding cybersecurity and Zero Trust implementation. Additionally, we did document analysis of network security, security policies, incident reports, and compliance documentation to provide a comprehensive understanding of the institutional context and security posture. Through observation and working with the network administrator we collected information about network topology information, access control policies, authentication protocols, encryption standards, and monitoring tool configurations. The data is collected in various formats, including configuration files, network diagrams, policy documents, and system logs. The data composition included details about network devices, user accounts, access permissions, encryption keys, and security policies. The data collection focused on the department of ICT within the University. We mainly used interviews, questionnaires and observation to gather this information.

This data helped us get a comprehensive understanding of the institution's network infrastructure, security posture, and compliance with established security standards. It facilitates analysis and comparison of network segmentation, access control policies, authentication protocols, encryption standards, and monitoring tools across different facilities and environments.

3. Identification of Zero Trust Implementation Strategies

Based on the collected data, we analysed the network segmentation, access control mechanisms, authentication protocols, encryption standards, and monitoring tools employed to enforce Zero Trust principles. The analysis involves evaluating the effectiveness of network segmentation in isolating critical assets and limiting lateral movement of threats. This includes assessing the segmentation policies, firewall configurations, and network architecture. Access control mechanisms such as role-

based access control (RBAC) and access control lists (ACLs) are analysed to ensure that only authorized users and devices have access to specific resources. This includes reviewing user accounts, group memberships, and permissions. Encryption standards such as AES, RSA, and TLS are evaluated to ensure data confidentiality and integrity. This includes reviewing encryption algorithms, key management practices, and SSL/TLS configurations. Monitoring tools such as SIEM (Security Information and Event Management) systems, IDS/IPS (Intrusion Detection/Prevention Systems), and endpoint detection and response (EDR) solutions are examined to detect and respond to security incidents. This includes reviewing alerting mechanisms, log retention policies, and incident response procedures. This analysis provided an insights into the strengths and weaknesses of each security component and identifies areas for improvement to enhance the overall security posture of the institution.

4. Evaluation of Effectiveness and Challenges

The study also evaluated the effectiveness of Zero Trust security implementation in addressing cybersecurity threats and enhancing security posture within the decentralized network of the institution. Key performance indicators such as reduction in security incidents, improvement in threat detection and response capabilities, user satisfaction with access controls, and compliance with regulatory requirements are assessed. Additionally, the stakeholders were able to give recommendations and challenges such as resistance to change, resource constraints, technical complexities, and organizational silos. We evaluated the network availability, data confidentiality for students, user authentication and multifactor authentication. Through a survey we issued inform of a questionnaire we benchmarked the use of zero trust within the institutions and found out some limiting factors. This helped the study find out the gaps and challenges and how zero trust can be implemented within the institution. An analysis from the evaluation was done as shown in chapter 4 below. The case study methodology provided a systematic approach to examine the implementation of Zero Trust security in decentralized networks within institutions of higher learning. By selecting appropriate case subjects, collecting relevant data, analyzing implementation strategies, evaluating effectiveness, and documenting lessons learned. The case study offers valuable insights and best practices for enhancing cybersecurity resilience and mitigating threats in complex network environments. As institutions continue to navigate evolving cybersecurity challenges, the case study methodology serves as a valuable tool for knowledge sharing, collaboration, and continuous improvement in cybersecurity practices.

3.1.2. The methodological steps of implementing zero trust within the institution.

In the ever-evolving landscape of cybersecurity, where traditional security models are becoming

inadequate against sophisticated threats, the Zero Trust model has emerged as a paradigm shift. Institutions are entrusting sensitive data and critical systems to Zero Trust techniques inorder to increase on security. This approach challenges the conventional notion of a trusted perimeter and advocates for continuous verification, irrespective of the user's location or the network's boundaries. Implementing Zero Trust within an institution requires a step by step approach from initial assessment to continuous evaluations. The methodology below provides a structured approach to implementing a Zero Trust within an institution, emphasizing having a dedicated team, a road map for implementation, and also evaluating iteratively.

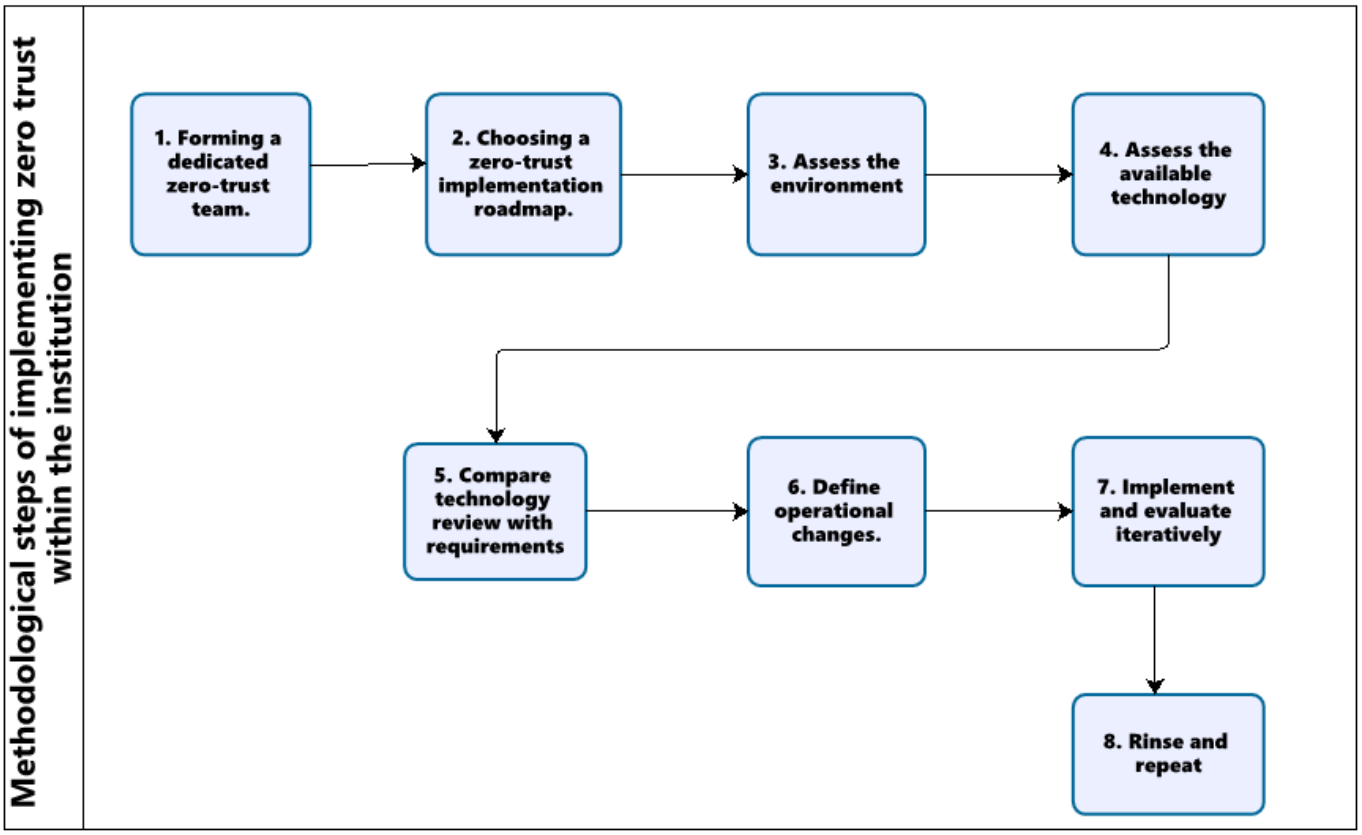

Figure 3.2; Showing the methodological steps of implementing zero trust (Irei,2022)

1. Forming a dedicated zero-trust team.

In the first step of implementation we formed a team in order to sensitize them about zero-trust. We discussed that zero-trust is the most important initiative an enterprise can undertake. A list of participants was formed which included the network administrators, infrastructure admin and then the end users for example students. All these helped us in coming up with a strong implementation team.

Table 3.1; The parameters used to form teams for implementation;

TASK	ACTIVITY
Identified Key Stakeholders:	Determined the key stakeholders who will be involved in the Zero Trust implementation. This may include representatives from IT, security, compliance, operations, and executive leadership.
Established Leadership	Appointed a senior leader or executive sponsor to oversee the Zero Trust initiative. This individual should have the authority to drive decision-making and allocate resources effectively.
Assembled Cross-Functional Team	Formed a cross-functional team comprising experts from various departments, including IT, security, networking, compliance, and risk management. Ensured diversity in expertise to cover different aspects of Zero Trust implementation, such as identity management, network security, data protection, and compliance.
Defined Roles and Responsibilities:	Clearly define roles and responsibilities for each team member based on their expertise and domain knowledge. Assign specific tasks and objectives to team members, aligning them with the overall goals of the Zero Trust initiative.

2. Choosing a zero-trust implementation roadmap.

After selecting a team we worked together to form a zero-trust strategy based on the University environment. We considered users and device identity within the organization because there are a

lot of students that access the institution platform using these devices especially online for example the eLearning platforms. In the eLearning platform users mostly use login credentials as an identity and access management method, this helped us understand how to improve on the security. We proposed a multifactor authentication technique to strengthen the login of the platform. We worked with the network administrator to improve on the network of the University. The network administrator was advised to apply automatic network controls to make access dynamic, through the use of scripts to revoke authorization. This was use to improve on the security within the network of the institutions. The administrator was also advised to use network encryption and secure routing, this was done within the devices where routing was controlled and validated and sessions encrypted. The institution was advised to use a centrally managed firewall to manage all resources in the network.

3. Assess the environment

In this step we looked at understanding the controls across the environment inorder to help us deploy the zero trust strategy smoothly. In this we asked questions around the security controls. We asked questions around the security controls with the institutions in terms of firewalls and web application gateways. What are the security controls in terms of endpoint security? The administrators were asked if there are any access controls. What information gaps are there? If you are unaware of the security classification of the data, it is impossible to grant granular access to that data. Unclassified data is an area of information that has to be filled in as part of a zero- trust approach. We also applied tools like **SSL Checkers**: Tools like SSL Labs' SSL Test can help you verify the SSL configuration of the website. **Security Headers Checkers**: Tools like SecurityHeaders.com can help you assess if the website is using appropriate security headers. **Vulnerability Scanners**: Tools like OWASP ZAP or Nessus can help you scan the website for potential security vulnerabilities. These helped us check the vulnerabilities within the e-learning platform.

4. Assess the available technology

Evaluating the existing technology landscape and identify potential gaps in achieving a zero-trust architecture. Concurrently or subsequently, analyze emerging technologies that can support a zero- trust initiative, such as micro segmentation, virtual routing, and stateful session management.

Recognize the evolving capabilities of Identity and Access Management (IAM) systems, focusingon increasing granularity and dynamism.

5. Compare technology review with requirements

Compare the findings from the technology review with the specific technology requirements for your zero-trust implementation. Determine which technologies align closely with your objectives and can address the identified gaps. This comparison will inform the development, prioritization, andlaunch of key zero-trust initiatives.

6. **Define operational changes.**

Understand that zero-trust strategies have the potential to bring significant changes to security operations. Identify the manual tasks that can be automated to align with the zero-trust approach. Modify or automate these manual tasks to ensure seamless integration with the evolving security landscape and prevent any security gaps.

7. **Implement and evaluate iteratively**

Begin implementing the chosen technologies and initiatives based on the defined priorities. Continuously assess the effectiveness of the implemented solutions by using security Key Performance Indicators (KPIs). Measure metrics such as mean total time to contain incidents, aiming for a significant decrease as the organization progresses towards a zero-trust model.

8. **Rinse and repeat**

Iterate on the implemented solutions and initiatives based on the evaluation results and evolving security landscape. Continuously review emerging technologies and advancements to stay updated with the latest opportunities for enhancing the zero-trust architecture. Repeat the methodology periodically to ensure ongoing improvements and adaptability to changing security requirements.

3.2 Proposed design of the model.

The transport access control (TAC) layer is used by the proposed access control policy to extract and examine TCP packets from incoming traffic. However, HTTP is utilized as the application layer protocol to establish a TCP connection with the cloud server/resources. When establishing a session with cloud resources, the zero-trust network manually verifies each untrusted IP address. The authentication of IP addresses is handled by the existing identity access management (IDM), which includes cloud services like Amazon Web Services (AWS) or Microsoft Web Directory. The IP addresses arriving from each host are given explicit trust, and IDM enables the creation of TCP sessions for extending access to the cloud services. Credentialed hosts send the IP addresses associated with the ARP queries. After receiving the ARP answers, the network parameters that match the IP addresses were put in the ARP table. The ARP protocol also does MAC address retrieval. Instead of inspecting the full TCP packet, the explicit TCP header has

been checked for the port number and destination IP address, which minimizes the time required to examine each individual TCP packet. It now keeps the network's high bandwidth and low latency. Our access control policy should be put into effect at a virtual security gateway where authenticated IP addresses are sent through. The proposed approach's architecture is shown below. The obligation for giving access to particular IP traffic is further taken on by the access control policy. The policy would automatically discard any IP addresses that match the network characteristics, and an alert message would be produced.

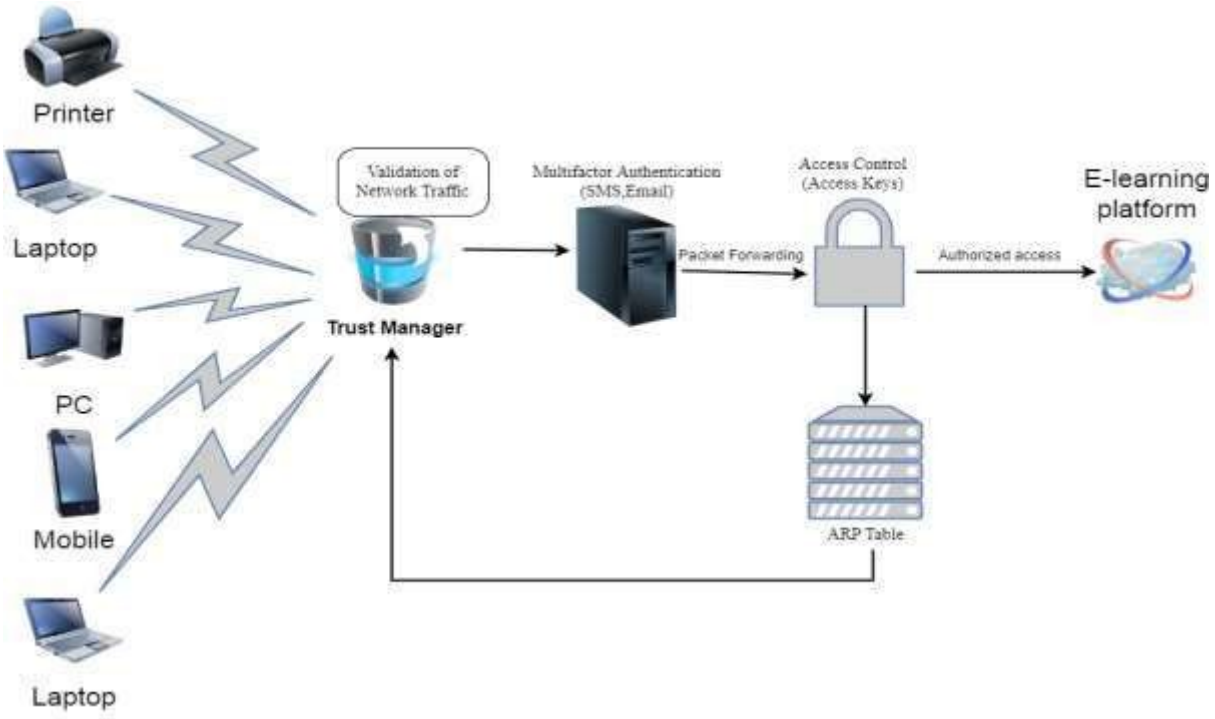

Figure 3.3;Showing the proposed architecture for higher institutions of learning.

In response to the evolving cyber security landscape and the unique challenges faced by higher learning institutions, we propose a comprehensive Zero Trust Implementation Framework. This framework aims to establish a proactive and adaptive security posture that eliminates implicit trust and ensures continuous verification and validation of all users, devices, and network traffic.

Key Components:

1. **Identity-Centric Authentication:**

Our model prioritizes identity-centric authentication, requiring users to authenticate their identities before accessing any network resources. Multi-factor authentication (MFA) mechanisms, including biometrics, tokens, and one-time passwords (OTPs), are implemented to enhance security and mitigate the risk of unauthorized access.

2. **Micro-Segmentation of Network:**

Micro-segmentation is employed to divide the network into smaller, isolated segments based on user roles, device types, and sensitivity of data. Each segment is assigned unique access controls, minimizing the lateral movement of threats and limiting the impact of potential breaches.

3. **Continuous Monitoring and Anomaly Detection:**

Continuous monitoring and anomaly detection mechanisms are integrated to analyze network traffic patterns, user behavior, and device activities in real-time. Machine learning algorithms are utilized to detect suspicious activities, anomalies, and deviations from established baselines, enabling proactive threat response and mitigation.

4. **Encryption and Data Protection:**

Encryption protocols, such as TLS/SSL, are implemented to secure data in transit and at rest. Data encryption ensures confidentiality and integrity, safeguarding sensitive information against unauthorized access and interception by malicious actors.

5. **Zero Trust Policy Enforcement:**

Zero Trust policies are enforced at every layer of the network infrastructure, including endpoints, applications, and data repositories. Access controls are dynamically enforced based on contextual factors such as user identity, device posture, and location, ensuring that only authorized entities are granted access to specific resources. Our proposed Zero Trust Implementation Framework offers a holistic approach to enhancing cyber security in higher learning institutions. By prioritizing identity-centric authentication, micro-segmentation, continuous monitoring, and policy enforcement, this framework enables institutions to mitigate security risks, protect sensitive data, and maintain a secure and resilient network infrastructure in an evolving threat landscape. Further research and collaboration with industry partners are recommended to validate and refine the proposed model for practical implementation.

3.4. System Architecture

Network security has long interfered with people's ability to study and work normally and has greatly slowed the advancement of Internet technology. Information and data in the network system are greatly at danger of leakage in an unsecure network environment. So at the information and data stored in the network may be safely secured and the risks of virus invasion and control are avoided, it is vital to strengthen network security management and optimize the network environment through network security maintenance.

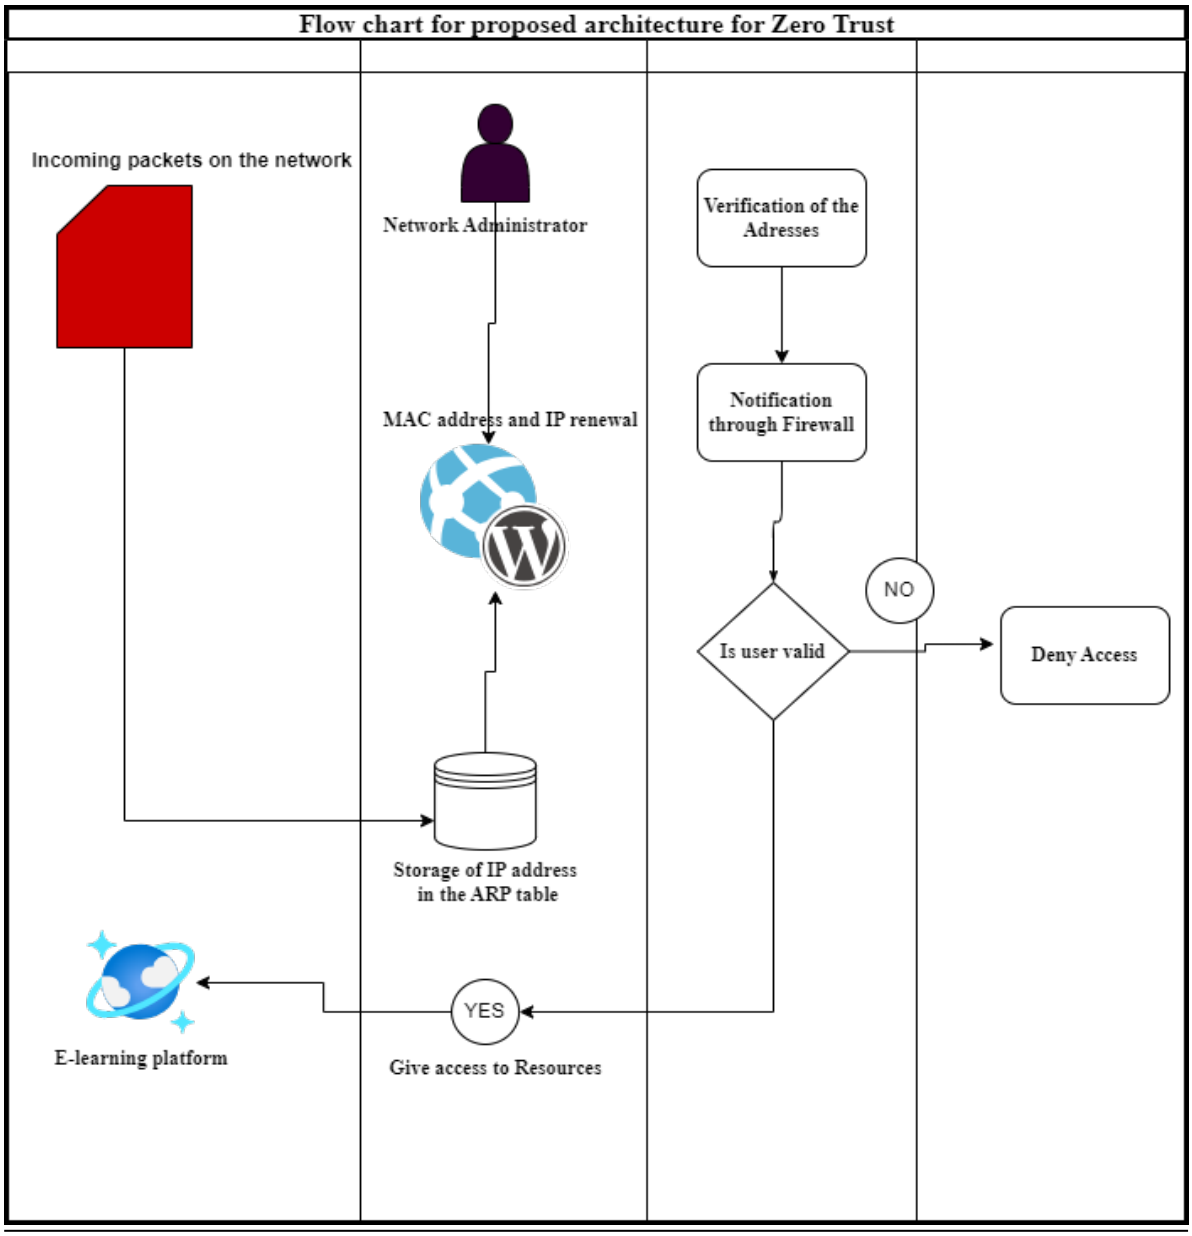

Figure 3.4 Showing the flow chart of the proposed zero trust network

3.4.1 Evaluation Metrics

In a system architecture for implementing Zero Trust in higher learning institutions, several performance metrics can be used for evaluation to ensure the effectiveness and efficiency of the implementation. Here are some key performance metrics commonly used in such contexts:

1. Authentication Success Rate:

This metric measures the percentage of authentication attempts that are successfully validated. A high authentication success rate indicates that the authentication mechanisms implemented as part of the Zero Trust model are functioning effectively.

2. Network Latency:

Network latency refers to the time it takes for data packets to travel from the source to the

destination across a network. Monitoring network latency can help assess the performance impact of implementing Zero Trust measures, such as encryption and authentication, on network communication.

3. Access Control Violations:

This metric measures the number of access control violations detected within the system. A low number of access control violations indicates that the access control policies implemented as part of the Zero Trust model are effectively preventing unauthorized access to resources.

4. User Experience Feedback:

User experience feedback collected from students, faculty, and staff can provide valuable insights into how the Zero Trust model is perceived and experienced by end-users. Feedback on factors such as ease of access, performance impact, and overall satisfaction can help identify areas for improvement.

5. Incident Response Time:

Incident response time measures the time it takes to detect, analyze, and respond to security incidents within the system. A lower incident response time indicates that the organization is effectively detecting and mitigating security threats in a timely manner.

6. Resource Utilization:

Monitoring resource utilization metrics, such as CPU usage, memory usage, and disk I/O, can help assess the impact of implementing Zero Trust measures on system performance and resource consumption.

7. Compliance with Security Standards:

Compliance with relevant security standards and regulations, such as GDPR, HIPAA, or FERPA, can serve as a performance metric for evaluating the effectiveness of the Zero Trust implementation in meeting regulatory requirements and ensuring data protection and privacy.

8. Audit Trail Integrity:

Audit trail integrity measures the completeness and accuracy of audit logs generated by the system. Ensuring the integrity of audit trails is critical for maintaining accountability, traceability, and compliance with security policies. Discussing these performance metrics allowed stakeholders to assess the effectiveness, efficiency, and impact of the Zero Trust implementation on the organization's security posture, user experience, and overall operational efficiency. Regular monitoring and evaluation of these metrics enable organizations to identify areas for improvement and continuously optimize their Zero Trust architecture to address evolving security threats and requirements.

Chapter 4. R ESULT ANALYSIS AND DISCUSSION

To obtain user feedback we talked with stakeholders like network administrators, system users and web administrators to gauge how easy it is to use, how it affects productivity, and how the decentralized network resources safeguarded by the zero-trust paradigm are generally applied within the university environment. We encouraged the stakeholders to carryout training and awareness on the guidelines of understanding and adhering to the zero trust security rules.

4.1. Result Analysis.

The study performed a result analysis where the answers from interviews and questionnaires were analysed and reported as below. The results show the magnitude of using zero trust within the organization, challenges and recommendations from the respondents. It provides an insight of the performance of different departments when it comes to zero trust implementation.

Table 4.1, Showing the responses from participants

Individual Role	Years of Experience	Department	4. How familiar are you with the concept of Zero Trust Security?	5. Have you received any training or education on Zero Trust Security?	6. How would you describe the current security measures in place within your institution's network?	7. Are there specific security challenges you have encountered within the current network infrastructure?	8. To what extent do you believe a Zero Trust Security model is suitable for decentralized networks in higher education?
Student	1	Programming	Somewhat familiar	No	Adequate but could be improved	No	
Student	7	Computing	Somewhat familiar	No	Adequate but could be improved	Not Sure	
Administrator	2	IT	Not familiar at all	No	Adequate but could be	No	

					improved		
Student	Since 2012	BLIS in 2012 and MIS in 2018	Not familiar at all	No	Adequate but could be improved	Yes	Theft , I have ever lost my laptop
Student	4		Very familiar	No	Strong and effective	No	
Staff	3	Information Technology	Somewhat familiar	No	Adequate but could be improved	No	
Student	3	MIT	Very familiar	Yes	Adequate but could be improved	No	
Staff	2	Information Technology	Not familiar at all	No	Adequate but could be improved	No	
Student	6	Networks	Somewhat familiar	No	Adequate but could be improved	Not sure	
Administrator	1	IT	Somewhat familiar	Yes	Inadequate	Not sure	
Staff	8	IT	Very familiar	No	Adequate but could be improved	Yes	
Student	10	Information Systems	Not familiar at all	No	Adequate but could be improved	No	

Recommendations from Respondents.

In this research we were able to get recommendations from respondents on how zero trust can be implemented successfully. The respondents were chosen purposively and issued questionnaires in order to evaluate an understanding of zero trust.

10. What recommendations do you have for a successful implementation of a Zero Trust Security model?
Ensure you have resources to implement and maintain the model once in use. Training
Train members before use of the model and to show them the purpose of t
Planning is very key on a strategy to use that will include, operational considerations,

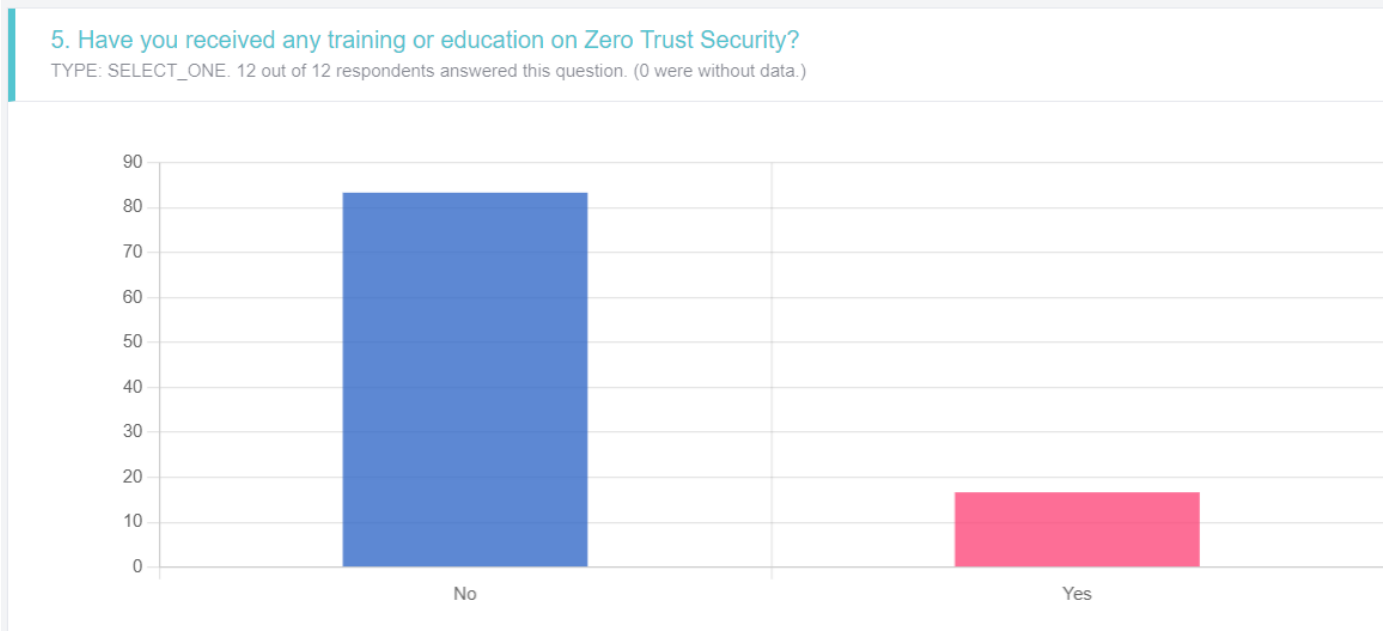
technology tools etc
Create Awareness before implementation
Awareness is key
Implement multi factor authentication mechanism to ensure CIA.
Creating awareness on the importance of such an implementation for application end users.

Graphical Representation of Results.

In the evaluation we asked questions around the familiarity of zero trust within the University, where 40% of the participants showed that they are somewhat familiar with zero trust implementations. The current state of Zero Trust implementation in higher education institutions shows significant alignment with baseline research recommendations. While there is a reasonable level of familiarity with Zero Trust principles, increased training and continuous adaptation are necessary to address the specific challenges of decentralized networks. By following a phased approach and leveraging advanced security tools, institutions can enhance their security posture and protect their sensitive data against evolving cyber threats.

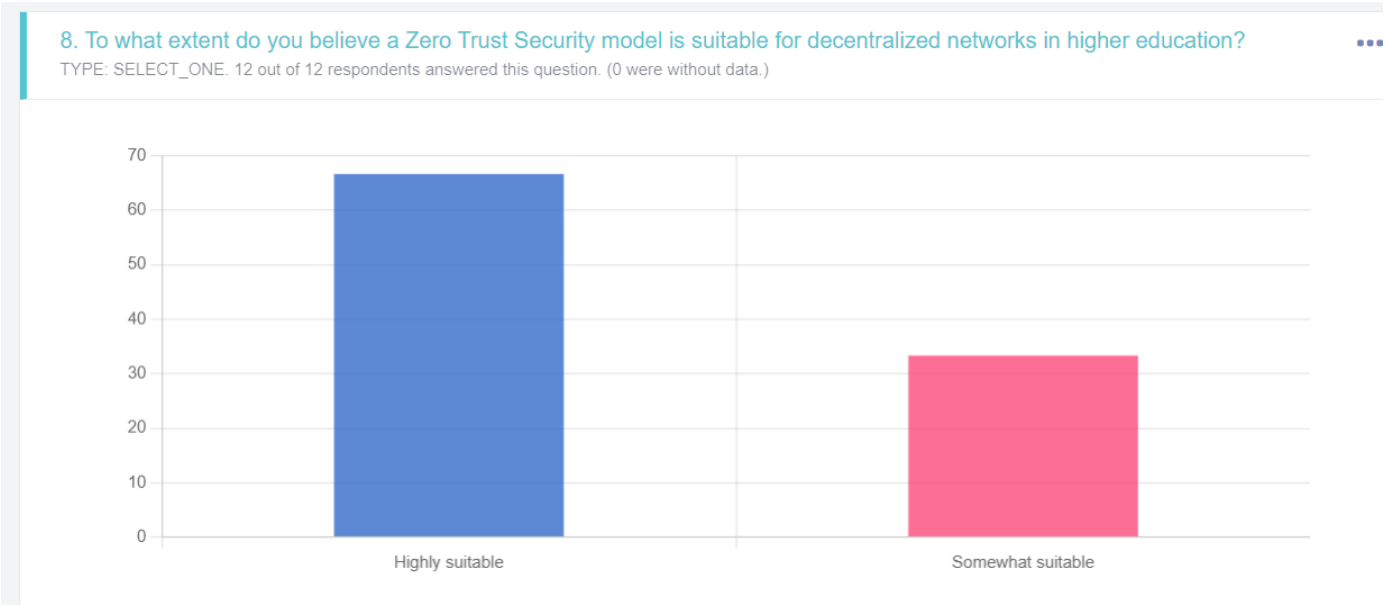
In the evaluation we also wanted to understand whether the institutions provides training on zero trust, almost 80% of the respondents said they have not had training or education on zero trust security. This shows that there is still a gap in terms of awareness on zero trust. The evaluation reveals a significant gap in training and awareness regarding Zero Trust security within higher education institutions. By benchmarking against baseline research, it is evident that comprehensive training programs and

effective resource allocation are crucial for successful Zero Trust implementation. Addressing these gaps through targeted initiatives will enhance the institution's security posture and resilience against cyber threats



In the evaluation, almost 80% of participants agreed that there is a pressing need for improvement in the security measures within their institutions, indicating that current systems are inadequate. This overwhelming consensus reflects a widespread recognition of vulnerabilities and the potential risks associated with insufficient security protocols. Also less than 10% of the institutions were reported to have strong and effective security measures in place. This disparity highlights a critical gap between existing security frameworks and the robust, adaptive measures required to mitigate modern cyber threats effectively. Institutions of higher learning, with their open and collaborative environments, face unique challenges that necessitate the adoption of comprehensive security strategies such as Zero Trust. The low percentage of institutions with effective security underscores the urgency for deploying advanced security solutions, continuous monitoring, and dynamic access controls to safeguard sensitive data and infrastructure against evolving cyber threats.

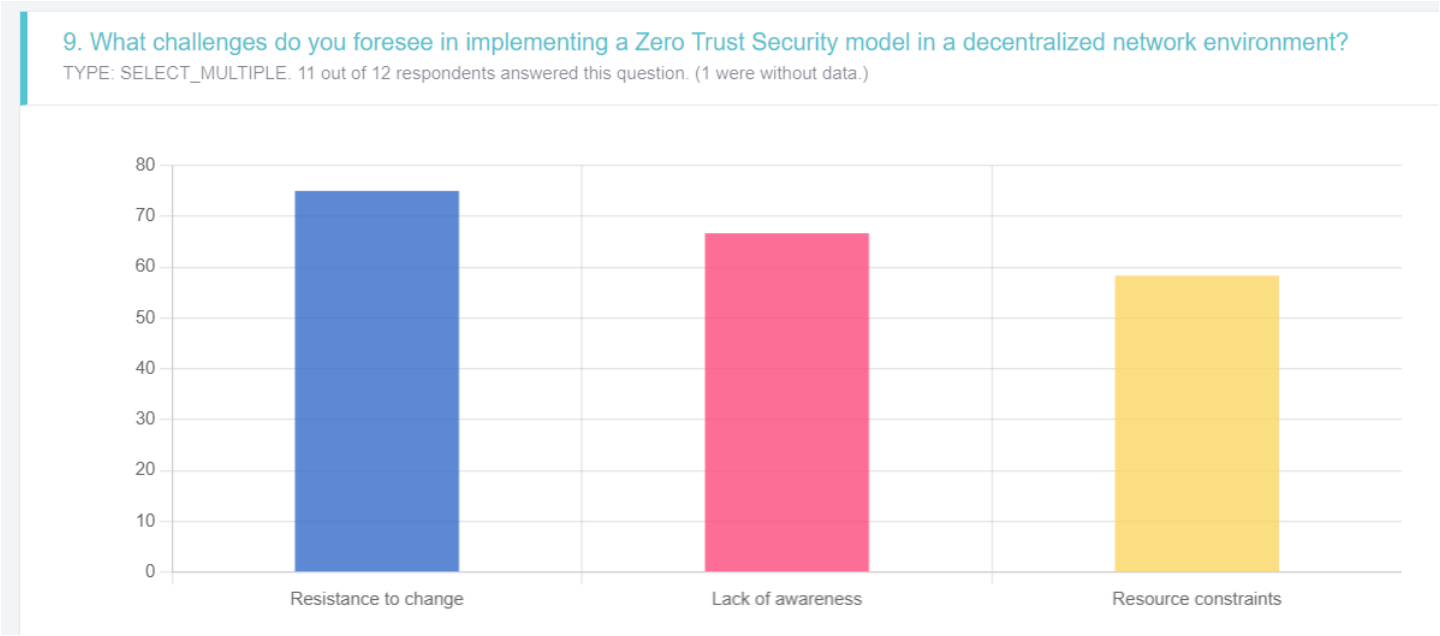
In the evaluation almost 70% believe a Zero Trust Security model is suitable for decentralized networks. This shows that institutions are increasingly recognizing the necessity of adopting a Zero Trust approach to bolster their network defenses. Given the distributed nature of decentralized networks, traditional perimeter-based security measures are insufficient in safeguarding against sophisticated cyber threats. Instead, embracing a Zero Trust framework entails verifying every user and device, regardless of their location within the network, and continuously monitoring for anomalous behavior. This proactive stance aligns with the dynamic nature of decentralized networks, where traditional notions of trust must be re-evaluated in favor of a more vigilant and adaptive security posture. Therefore, institutions are urged to support the need for Zero Trust adoption and prioritize its implementation to fortify their digital infrastructures against evolving cyber risks.



There are different challenges that were identified in the implementation of zero trust with a high rate of resistance to change with a percentage of over 70%, 65% agree that there is lack of awareness within the institutions. A significant barrier in the implementation of zero trust strategies is the high rate of resistance to change among employees and organizational leadership. Research indicates that over 70% of organizations encounter resistance when attempting to transition to a zero trust model. This resistance is often rooted in several factors: Cultural Resistance: Many organizations have established cybersecurity protocols and frameworks that employees are familiar with but transitioning to a zero-trust model often meets resistance because employees this it disrupts established workflows and necessitates retraining. In an interview with the networks department they reported that Zero trust architecture is perceived as complex and demanding. That it requires a comprehensive overhaul of existing security systems, the implementation of continuous monitoring and verification processes, and the integration of advanced technologies. This perceived complexity can deter organizations from fully embracing the change. Many also reported that implementing zero trust requires significant investments in terms of time, money, and human resources which is not provided by institutions. Institutions may resist due to concerns over the costs associated with the necessary technology upgrades, training, and potential disruptions during the transition period.

In addition to resistance to change, a lack of awareness and understanding of zero trust principles and benefits is a critical challenge. Studies show that 65% of organizations agree that there is a significant lack of awareness within their institutions. This lack of awareness manifests in several ways: Knowledge Gaps: Many employees and even IT professionals were not fully understanding what zero trust entails. They reported that there is need for proper training on the advantages of zero trust. Also effective communication about the need for zero trust and its benefits is often lacking.

Organizational leadership may fail to adequately convey why zero trust is necessary and how it improves security posture, leading to misconceptions and skepticism among employees. Hence comprehensive training is essential to ensure that all stakeholders understand zero trust principles and how to apply them in their daily operations. Without such training, employees are ill-prepared to adapt to the new security measures. Forrester research has emphasized that organizational inertia and cultural barriers are primary obstacles to zero trust adoption. Their findings suggest that leadership commitment and comprehensive change management strategies are crucial to overcoming these hurdles. Gartner also reports that many organizations struggle with the transition due to inadequate understanding of zero trust's operational and technical requirements. They highlight the need for clear communication and education to bridge the awareness gap.



Ponemon Institute identified that resistance to change is exacerbated by a lack of skilled personnel who can manage and implement zero trust frameworks. Their studies recommend investing in training and development to build the necessary expertise within organizations.

Chapter 5. Recommendations and Conclusion

5.1. Recommendation and Future Research

The zero-trust idea is a novel strategy; no standard has yet been made public. For most implementers, selecting a model is always a time-consuming process. Interviewing all parties always takes a lot of time and resources because everything pertaining to higher education is private. To guarantee a low rate of cyberattacks on the new and emerging institutions, one of the ideas for future research that needs to be looked into is the comparison of security models employed in various institutions. The study's next steps involve creating a zero-trust algorithm to protect the data and information stored within the university and putting the suggested approach into practice within an organization. Ensuring the security of all data and infrastructure inside an institution requires addressing all important departments. Given the high percentage of respondents calling for enhanced security measures, it's clear that there is a substantial need for institutions to prioritize the development and implementation of Zero Trust security models. These models focus on continuous verification, the principle of least privilege, and assuming breaches as inevitable, thereby minimizing the potential impact of any security incidents. Educational institutions should allocate resources to not only bolster their technological defenses but also to educate and train staff and students on Zero Trust principles. By doing so, they can create a more secure and resilient digital environment that protects against both internal and external threats

5.2. Conclusions

In an institution we recommend that Zero trust should be put at the forefront inorder to keep all information of given organizations safe. Many staff members do not understand the importance of zero-trust and why an institution should implement it especially in the networks. The head of security should always be advised to ensure trainings are done frequently for the institutions to be safe. The major goal of zero trust is to make the institution safe and all its data protected from any intruders. More security tools are advised to be installed especially those that manage access control within the organization. In further research we encourage a more intensive study that focuses on challenges and outcomes of neglecting zero trust in institutions of higher learning. This will help appreciate this study and also focus on encouraging institutions to embrace zero trust models. Institutions need to have a wider awareness that security threats are real and find ways of how to tackle them.

COMPARATIVE ANALYSIS OF SOME DIGITAL FORENSIC TOOLS USED BY THE NIGERIA POLICE FORCE

BY

OLUSOJI ABRAHAM OBIDEYI

ACE22120039

A Dissertation Submitted in Partial Fulfilment of the Requirements for the Award of the Degree of Masters of Science in Cyber Security (M.Sc Cyber Security)

At the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), National Open University of Nigeria (NOUN)

DECLARATION

I, Olusoji Abraham Obideyi, hereby declare that the project work entitled **COMPARATIVE ANALYSIS OF SOME DIGITAL FORENSIC TOOLS USED BY THE NIGERIA POLICE FORCE** is a record of an original work done by me, as a result of my research effort carried out in the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), National Open University of Nigeria under the supervision of Professor Idris Ismaila.

_____

Student's Signature & Date

CERTIFICATION/ APPROVAL

This is to certify that this study was carried out by Olusoji Abraham Obideyi (ACE 22120039) in the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), National Open University of Nigeria, under my supervision.

Prof. Idris Ismaila _____
Supervisor

Dr. Adeyinka Abiodun _____
Course Coordinator

Prof. Grace E. Jokthan _____
Director, ACETEL-NOUN

… … … … … … … _____
External Examiner

DEDICATION

This research work is dedicated unto God Almighty, the Maker of Heaven and Earth, who is my Creator and Helper. To Him alone be all the glory forever and ever! Amen.

ACKNOWLEDGMENTS

I, first and foremost, thank the Almighty and All-Sufficient God, who has given me the opportunity of life and livelihood to go through this phase of life successfully. I cannot thank Him enough. However, with every breath of mine, I will continue to serve Him and His people as He has so purposed for me.

I also thank so immensely my parents, Reverend and Pastor (Mrs.) Theophilus Olaniyi Obideyi for their parental guidance and support from my birth till date. I thank my other family members as well for their unflinching support throughout the process of producing this work. I also thank the Inspector-General of Police and my colleagues at the Nigeria Police Force (NPF) for allowing me to improve on the job through this exercise, I will never take this privilege for granted by the grace of God. I also need to thank all the respondents to my questionnaire for this study, who are my senior and junior colleagues in the NPF, for their feedbacks and input on this work.

I am unreservedly indebted with gratitude to my indefatigable supervisor, Prof. Idris Ismaila, who has remained my great helper, motivator, and inspiration throughout the period of putting this work together. His input to this work is immeasurable, I appreciate his professional prowess at guiding me to ensuring this piece is worth the time and resources committed to it. Thank you so much, Sir. In like manner, I must thank so profusely the entire Management and Staff of Africa Center of Excellence on Technology Enhanced Learning (ACETEL) at the prestigious National Open University Nigeria (NOUN) for their professional impact in my life over this Masters Degree awarding programme. I need to specially thank my Course Coordinator, in person of Dr. Adeyinka Abiodun for making my sojourn on this study a huge success.

At this juncture, I want to lovingly appreciate my adorable wife, Mrs. Oluwaseun Adeola Obideyi, and our lovely children who understood my frailty and stood by me all through the thick and thin of the process involved in producing this research work.

God bless you all for helping me go through this successfully.

NPF – The Nigeria Police Force

ABSTRACT

The digital realm presents a complex battleground for modern law enforcement, demanding robust digital forensics capabilities. This study investigates the effectiveness of three digital forensics tools – EnCase, AccessData FTK, and Cellebrite – employed by the Nigerian Police Force (NPF).

Through a survey approach, the research gathered data from NPF officers regarding their user experiences with these tools. The analysis focused on effectiveness, ease of use, data integrity, processing speed, interoperability, and adaptation to evolving encryption technologies.

The findings reveal that all three tools offer functionalities relevant to the NPF's needs. However, user experiences suggest Cellebrite is perceived as the most effective tool, with strengths in user-friendliness, data integrity, and processing speed. EnCase integration challenges and concerns regarding its effectiveness in handling encrypted evidence warrant further investigation.

Based on the analysis, the study recommends investing in training programs, exploring standardization on Cellebrite, addressing EnCase integration issues, implementing standardized benchmarks for objective performance evaluation, and providing continuous training on encryption trends for officers.

This research contributes to the field by offering a user-experience-focused analysis of digital forensics tools within a developing nation context. It highlights the importance of balancing user experience with objective performance metrics for effective tool selection within law enforcement agencies.

CHAPTER ONE: INTRODUCTION

1.1 Background to the Study

Cybercrime is a global phenomenon, and Nigeria has experienced a significant rise in recent years (Babayo et al., 2021). The increase in cybercrimes presents numerous challenges for law enforcement, highlighting the critical role of digital forensics in combating these digital threats. In addition, the widespread adoption of technology across various sectors has fuelled the surge in cybercrime, necessitating the development and use of advanced digital forensics tools by law enforcement agencies worldwide (Smith, 2018; Jones & Brown, 2016).

In Nigeria, the growth of internet penetration and mobile phone usage has provided new opportunities for cybercriminals (Oladokun, 2020). The high unemployment rates and harsh economic conditions further exacerbate the situation, pushing individuals towards cybercrime as a means of survival (Oladokun, 2020). Additionally, inadequate educational systems and limited awareness about cybersecurity best practices leave many individuals and organizations vulnerable to attacks (Oladokun, 2020). Law enforcement agencies, particularly the Nigeria Police Force (NPF), face significant hurdles due to these factors and the increasing sophistication of cyber threats (Oladokun, 2020).

The NPF's ability to effectively combat cybercrime is also hindered by limited resources and training. The rapid technological advancements in data storage formats, encryption techniques, and device types necessitate continuous adaptation and upgrading of digital forensic capabilities. The challenges faced by the NPF are not unique; law enforcement agencies globally are in a constant race to stay ahead of evolving cyber threats and criminal methods.

To address these challenges, the NPF has incorporated digital forensics into its operations, relying on various tools to gather, analyse, and present digital evidence. Digital forensics involves the identification, preservation, extraction, and documentation of digital evidence

from various devices and storage media. It plays a crucial role in investigations, helping to uncover cybercrimes, fraud, and other illicit activities conducted through digital means.

Three prominent digital forensics tools employed by the NPF are EnCase, AccessData FTK, and Cellebrite. These tools are used to examine digital devices, recover deleted files, analyse file systems, and decode encrypted data. Each tool has its unique features, strengths, and weaknesses, making it imperative for the NPF to understand their comparative effectiveness in addressing specific investigative needs.

Digital forensic tools are indispensable in modern investigations, providing the means to handle vast amounts of digital evidence. EnCase, developed by Guidance Software, is widely acclaimed for its comprehensive features, including data acquisition, analysis, and reporting (Carrier, 2016). Its robustness in dealing with complex file systems and extensive support for various data formats make it a preferred choice among law enforcement agencies globally. Studies have highlighted EnCase's effectiveness in high-profile investigations, particularly in recovering deleted and encrypted files (Rogers et al., 2013).

AccessData FTK (Forensic Toolkit) is another critical tool, known for its powerful data indexing and search capabilities. It facilitates rapid processing and analysis of large data sets, making it highly efficient in time-sensitive investigations (Al Mutawa et al., 2016). FTK’s integration with database management systems enhances its ability to handle complex cases involving multiple data sources (Quick & Choo, 2018). Researchers have emphasized its utility in cybercrime investigations, particularly in scenarios requiring detailed content analysis and quick turnaround times (Casey, 2011).

Cellebrite, renowned for its expertise in mobile device forensics, offers unparalleled capabilities in extracting and analysing data from smartphones and tablets (Ovens & Morison, 2016). Its widespread use in law enforcement is attributed to its ability to support a broad range

of devices and operating systems, ensuring comprehensive data acquisition from diverse sources (Husain et al., 2019). Cellebrite's tools are particularly noted for their user-friendly interfaces and efficient data recovery processes, making them indispensable in mobile forensic investigations (Samani et al., 2019).

Despite the advancements in digital forensic tools, several challenges persist. The ever-evolving nature of digital technology means that forensic tools must constantly adapt to new devices, file formats, and encryption methods. This rapid evolution often outpaces the ability of law enforcement agencies to update their forensic capabilities, leading to potential gaps in their investigative processes (Garfinkel, 2010).

Furthermore, the volume of data involved in modern investigations can be overwhelming. As digital storage capacities increase, so does the amount of potential evidence that must be sifted through, analysed, and stored securely. This necessitates tools that not only have robust processing capabilities but also efficient data management and storage solutions (Grobler & Louwrens, 2017).

Interoperability between different forensic tools is another critical issue. The ability to seamlessly integrate various tools and share data without loss of integrity is essential for comprehensive investigations. Studies have highlighted the need for standardized data formats and interoperability protocols to ensure that forensic tools can work together effectively (Kohn et al., 2013).

In the context of the Nigeria Police Force, the adoption and effective utilization of these digital forensic tools are crucial. The rise in cybercrime rates in Nigeria has prompted a more proactive approach to digital investigations. However, resource limitations and the need for specialized training pose significant barriers. The NPF's efforts to integrate EnCase, AccessData FTK, and

Cellebrite into their investigative framework reflect a commitment to overcoming these challenges (Babayo et al., 2021).

Research indicates that continuous training and capacity building are essential for the NPF to maximize the potential of these tools (Eze, 2018). Moreover, collaboration with international bodies and participation in global cybercrime initiatives can enhance the NPF's capabilities and provide access to the latest technological advancements in digital forensics (Adesina, 2017).

Understanding the comparative strengths and weaknesses of EnCase, AccessData FTK, and Cellebrite is essential for optimizing their use within the Nigeria Police Force. This research aims to provide a detailed analysis that will inform strategic decisions, improve investigative outcomes, and contribute to the broader effort of combating cybercrime in Nigeria. Through this comparative study, the NPF can enhance its digital forensic capabilities, ensuring more efficient and effective responses to the growing threat of cybercrime.

1.2 Statement of the Problem

The increasing prevalence of cybercrime in Nigeria has presented significant challenges for law enforcement agencies, particularly the Nigeria Police Force (NPF). Despite the availability of various digital forensic tools, the NPF's capability to effectively combat cyber threats remains hindered by several critical issues. Existing research indicates that while tools such as EnCase, AccessData FTK, and Cellebrite are widely used in digital forensics, their comparative effectiveness in the context of the NPF has not been thoroughly examined.

Studies by Garfinkel (2010) and Quick and Choo (2014) highlight the importance of selecting appropriate digital forensic tools tailored to specific investigative needs (Garfinkel, 2010; Quick & Choo, 2014). However, there is a notable gap in research specifically addressing the performance and suitability of the tools under reference within the operational environment of the NPF. This gap includes challenges such as tool selection dilemmas, performance

limitations, data integrity risks, interoperability issues, and the need for adaptation to evolving encryption technologies. Garfinkel (2010) emphasized the complexities involved in choosing the right forensic tools from a plethora of options with varying features and functionalities (Garfinkel, 2010). Furthermore, Quick and Choo (2014) discussed the criticality of maintaining data integrity and ensuring the admissibility of digital evidence in court. They also point out that performance limitations and efficiency issues can significantly impact the speed and accuracy of digital investigations (Quick & Choo, 2014).

In view of the above facts, this research aims to address the problem of optimizing digital forensic tool selection and utilization within the NPF. The primary focus will be on evaluating the effectiveness, limitations, and interoperability of EnCase, AccessData FTK, and Cellebrite. By conducting a comprehensive comparative analysis, this study seeks to provide the NPF with actionable insights to enhance their digital investigative capabilities and improve the overall efficiency and accuracy of cybercrime investigations. Hence, the following questions are to be answered by this research:

1. What are the functionality and features of Encase, AccessData FTK, and Cellebrite in context of NPF Requirement?

2. What are the performance and efficiency of Encase, Access Data FTK, and Cellebrite in Handling Diverse Digital Evidence?

3. What are the Interoperability and Integration of EnCase, AccessData FTK, and Cellebrite within the NPF's Digital Forensic Framework?

1.3 Aim of the Study

The study aims to address the problem of optimizing digital forensic tool selection and utilization within the NPF. The primary focus will be on evaluating the effectiveness, limitations, and interoperability of EnCase, AccessData FTK, and Cellebrite.

1.4 Specific Research Objectives

a) To analyse the functionality and features of EnCase, AccessData FTK, and Cellebrite in the context of NPF's requirements

b) To assess the performance and efficiency of EnCase, AccessData FTK, and Cellebrite in handling diverse digital evidence

c) To evaluate the interoperability and integration of EnCase, AccessData FTK, and Cellebrite within the NPF's digital forensic framework

1.5 Scope of the Study

This research focuses on the comparative analysis of three prominent digital forensics tools—EnCase, AccessData FTK, and Cellebrite—employed by the Nigeria Police Force (NPF). The study will only consider the three specified tools to maintain specificity and depth in the comparative analysis. The research is limited to the NPF's operations within Nigeria. It does not extend to digital forensics practices in other countries or international contexts. The study will investigate how these tools are used within the NPF's operational framework, including various types of investigations involving digital evidence like cybercrimes and financial crimes. The study will assess the performance of the selected tools based on metrics relevant to the NPF's needs, such as processing speed, accuracy, data integrity, and overall efficiency. The study will not examine digital forensics practices outside Nigeria. It will not include other digital forensic tools beyond EnCase, AccessData FTK, and Cellebrite. The research will not delve into legal or policy frameworks governing digital forensics outside the operational use within the NPF. The research will not collect hard, quantitative or qualitative system information that violate confidentiality of the forensic tools in use for investigations by the NPF.

1.6 Significance of the Study

This study aims to provide significant contributions to the field of digital forensics, particularly within the context of the Nigeria Police Force (NPF), and has broader implications for the global law enforcement community. The outcome of this study is expected to enhance digital forensic practices both locally and globally. It is further expected to guide informed policy and strategic decisions, help in streamlining cybercrime investigations, promote digital forensics training. The study is also expected to serve as valuable resources for academics and practical knowledge within the law enforcement society and criminal justice systems. By addressing these areas, this research not only supports the NPF in its mission to combat cybercrime, but also contributes to the wider field of digital forensics, ultimately enhancing global cybersecurity resilience and law enforcement capabilities.

1.7 Justification of the Study

The rapid escalation of cybercrime in Nigeria presents a formidable challenge for the Nigeria Police Force (NPF). With the increasing sophistication of cybercriminal activities, there is an urgent need for effective digital forensic tools that can aid in the investigation and prosecution of such crimes. This study is justified for its ability to address the rising threat of cybercrimes globally, enhance law enforcement capabilities, fill research gaps by providing empirical data and practical insights which are directly applicable to the NPF. In conclusion, this study is justified by its potential to significantly enhance the NPF's digital forensic capabilities, thereby improving the overall effectiveness of cybercrime investigations and contributing to the broader goal of maintaining cybersecurity in Nigeria.

1.8 Definition of Terms

To ensure clarity and precision in understanding this research work, it is essential to define key words and terminologies used throughout the study. These definitions establish a common

understanding of key terms used in the thesis, providing a foundation for readers to grasp the nuances and context of the research.

Digital Forensics: The process of collecting, analysing, and preserving electronic evidence in a manner that is legally admissible during international best practices criminal justice systems. It involves investigating digital devices, data, networks, and systems to uncover, analyse, and respond to cybercrimes and other digital-related offenses (Anderson, 2019).

EnCase: A digital forensics tool developed by Guidance Software (now OpenText) used for acquiring, analysing, and preserving electronic evidence. It is widely employed in law enforcement and corporate investigations (Brown & Smith, 2018).

AccessData FTK (Forensic Toolkit): A digital forensics software suite developed by AccessData Group Inc. The FTK provides tools for data acquisition, analysis, and reporting, with a focus on digital investigations and e-discovery (Garcia & Lee, 2019).

Cellebrite: A digital intelligence company that provides digital forensics tools and services. Cellebrite's solutions are often used for mobile device forensics, enabling the extraction and analysis of data from smartphones and other mobile devices (Johnson et al., 2020).

Nigeria Police Force (NPF): The Nigeria Police Force is the primary law enforcement agency in Nigeria. It is responsible for maintaining law and order, preventing and investigating crimes, and ensuring public safety and security of lives and property across the country (Smith & Jones, 2017). The NPF includes specialized Departments, Sections and Units, among which some are focused on fighting cybercrimes and employing digital forensics.

Comparative Analysis: A method of evaluating and contrasting the similarities and differences between two or more subjects, in this case, digital forensics tools (EnCase, AccessData FTK, and Cellebrite) (Garcia, 2021).

Drawbacks: Limitations, weaknesses, or disadvantages associated with the use of digital forensics tools, which may hinder their effectiveness in specific contexts or scenarios (Brown, 2018).

Solutions: Practical recommendations or strategies proposed to address and overcome the identified drawbacks and challenges related to the use of digital forensics tools (Miller et al., 2021).

Processing Speed: The rate at which a digital forensics tool can analyse and process electronic evidence, often measured in terms of the time required to complete specific tasks or operations (Brown & Smith, 2018).

Data Accuracy: The reliability and precision of results obtained from digital forensic analysis, ensuring that the information extracted from digital devices is faithful to the original data (Anderson, 2019).

Data Integrity: The assurance that electronic evidence remains unaltered and authentic throughout the digital forensic process, maintaining its original state and reliability for legal purposes (Smith & Jones, 2017).

Interoperability: The ability of different digital forensics tools to work together seamlessly, facilitating collaboration and integration within the NPF's overall investigative framework (Gracia & Lee, 2019).

Encryption Technologies: Techniques and methods used to secure digital data, rendering it unreadable without the appropriate decryption key. The study explores how well digital forensics tools handle cases involving encrypted data (Brown, 2018).

CHAPTER TWO: LITERATURE REVIEW

2.1 Introduction

This chapter presents a comprehensive literature review conducted to build a strong foundation for understanding the digital forensics landscape, specifically focusing on EnCase, AccessData FTK, and Cellebrite. The review begins by exploring the theoretical frameworks and methodologies used in digital forensics. This establishes a fundamental understanding of the principles guiding investigations and approaches to handling electronic evidence to ensure its legal admissibility in cybercrime prosecutions.

Following this, the review delves into a detailed analysis of the context of digital forensics tools. It provides insights into the characteristics and functionalities of EnCase, AccessData FTK, and Cellebrite. By examining comparative studies from both national and international contexts, the review identifies trends, best practices, and challenges associated with these tools. Additionally, the review draws upon empirical studies to investigate the effectiveness and limitations of these tools within law enforcement, with a particular emphasis on their usage within the Nigeria Police Force. This comprehensive review aims to establish a solid foundation for the subsequent empirical investigation conducted in this research.

2.2 Theoretical Framework

A robust theoretical framework guides the research design, methodology, and analysis of a study. This research draws upon the following key frameworks to ensure a systematic, scientifically rigorous, and legally sound approach (Johnson 2020).

2.2.1 Locard's Exchange Principle

This foundational principle, established by Edmond Locard, posits that every interaction leaves a trace. In the context of digital forensics, this implies that digital devices exchanging information leave electronic traces that can be analyzed to reconstruct events. Understanding

and applying this principle is crucial for identifying, collecting, and interpreting digital evidence, aligning perfectly with this research's focus on analysing such traces left by interactions between law enforcement and digital devices. (Clough, 2010).

Edmond Locard, often referred to as the "Sherlock Holmes of Lyon," formulated the Locard's Exchange Principle in the early 20th century. His principle has since become a cornerstone of forensic science. Locard postulated that whenever two objects come into contact, there is an exchange of materials between them. This principle has profound implications for the field of digital forensics, where digital interactions leave behind traces that can be identified, collected, and analyzed (Casey, 2011).

2.2.1.1 Theoretical Basis for Locard's Exchange Principle

Locard's Exchange Principle is fundamentally based on the concept that every contact leaves a trace. This trace evidence, though often microscopic or invisible to the naked eye, can be critical in reconstructing events and identifying the involved parties. In the physical world, this might include fingerprints, hair, fibres, or soil. In the digital realm, traces include log files, metadata, digital footprints, and data remnants (Carrier, 2005).

2.2.1.2 Historical Evolution of Digital Forensics

The field of digital forensics has undergone significant transformation since its inception, driven by technological advancements and the growing sophistication of cyber threats. Understanding its historical evolution provides valuable context for the methodologies, tools, and challenges faced by forensic investigators today. Digital forensics originated in the late 1970s and early 1980s when computers began to play a central role in business operations and crime. Early investigations primarily focused on fraud cases involving mainframe computers, as businesses sought to address unauthorized access and data manipulation (Marcella & Menendez, 2008). These initial efforts lacked standardized methodologies and relied on

rudimentary tools tailored to specific systems. The landmark 1984 establishment of the Computer Analysis and Response Team (CART) by the FBI marked a pivotal moment. CART focused on investigating crimes involving digital systems, laying the groundwork for modern digital forensic practices (Casey, 2011). The 1990s saw the formalization of digital forensics as personal computers became widespread. Law enforcement agencies recognized the need for specialized tools and training to handle the increasing volume of digital evidence.

2.2.1.3 Historical Development of Certain Forensic Tools

EnCase was introduced in 1996 by Guidance Software, providing capabilities for data acquisition, file system analysis, and report generation. It quickly became a standard for law enforcement (Carrier, 2005). AccessData FTK (Forensic Toolkit) followed in 1997, offering powerful indexing and search capabilities, making it efficient for handling large datasets (Casey, 2011). Cellebrite, launched in 1999, emerged as a leader in mobile forensics, providing solutions for extracting and analysing data from mobile devices. This tool gained prominence as mobile phones became integral to daily life and crime investigations (Nelson et al., 2014).

2.2.1.4 Early Legal Recognition

Courts began admitting digital evidence for prosecution in the 1980s and early 1990s, as computers and digital technology became more prevalent in business and personal use. The exact timeline varies by jurisdiction. In the 1980s, as digital devices and computers started being used in criminal activities, such as fraud or hacking, the need for digital evidence grew. However, there was little precedent for how such evidence should be handled. The 1990s saw significant milestones in the recognition of digital evidence in court. A landmark case was **United States v. Olinger (1993)**, where the court admitted digital evidence (a hard drive) in a case involving child pornography. This case helped set a precedent for the inclusion of digital evidence in the legal process. In 1994, the **Computer Fraud and Abuse Act (CFAA)** in the U.S. was updated, making it easier for prosecutors to use digital evidence in cases of

cybercrime and unauthorized access to computer systems. In 1999, the **Federal Rules of Evidence** (in the United States of America) were amended to accommodate the use of digital evidence, including computer-generated records and other digital information, making it more accepted in legal proceedings.

From the 1990s onward, digital forensics techniques and standards evolved, leading to the widespread use of digital evidence in criminal and civil cases worldwide. Hence, courts began recognizing digital evidence as admissible, provided that proper handling and chain of custody were maintained. This period also saw the creation of guidelines for evidence handling, such as the Scientific Working Group on Digital Evidence (SWGDE) standards established in 1998 (SWGDE, 1998). The 2000s witnessed a rapid expansion of digital forensics, spurred by the proliferation of mobile devices, the internet, and new forms of cybercrime.

2.2.1.5 Introduction of Structured Frameworks for Digital Forensics

The development of structured frameworks like the Abstract Digital Forensics Model (ADFM) provided investigators with systematic methodologies for evidence collection and analysis (Reith et al., 2002). The release of international standards like ISO/IEC 27037 in 2012 formalized best practices for the identification, acquisition, and preservation of digital evidence (ISO/IEC, 2012).

Landmark cases like **United States v. Carey (1999)** established precedents for the scope of searches involving digital evidence, highlighting the need for clear procedural boundaries (Casey, 2011). The digital forensics field has since entered an era of rapid technological innovations, driven by the complexity of digital environments and the sheer volume of data. Tools now integrate Artificial Intelligence (AI) to automate repetitive tasks like keyword searching and pattern recognition, significantly enhancing efficiency (Quick & Choo, 2019). Advanced algorithms enable faster analysis of large datasets, reducing the time required for

investigations. The shift to cloud storage introduced challenges related to jurisdiction and data volatility. Tools like Magnet AXIOM have been developed to address these complexities, allowing investigators to retrieve and analyse cloud-based data securely (Ray & Khan, 2016). In fact, the rise of Internet of Things (IoT) devices has added new dimensions to digital forensics. Investigators now handle data from smart devices, wearables, and interconnected systems, requiring specialized techniques and tools (Garfinkel, 2013).

The future of digital forensics lies in addressing emerging challenges such as quantum computing, which threatens to render current encryption obsolete, and 5G networks, which enable faster and more decentralized data transfer. Continuous adaptation through research, training, and innovation will be essential to meet these challenges (Carrier, 2005; Jones, 2018). The historical evolution of digital forensics illustrates a journey from ad hoc approaches to a highly specialized discipline underpinned by robust tools and methodologies. The field has responded dynamically to technological changes and legal demands, evolving into a critical component of modern law enforcement and cybersecurity. By understanding its past, researchers and practitioners can better anticipate future challenges and advancements.

2.2.1.6 Application of Locard's Exchange Principle in Digital Forensics

In digital forensics, Locard's principle is applied to uncover and analyse digital evidence left behind by cybercriminals. Digital traces can include log files (records of user activities, system events, and network interactions) (Carrier, 2005); metadata (information about files and data, such as creation dates, modification dates, and access permissions) (Jones, 2018); digital footprints (evidence of online activities, including browsing history, emails, and social media interactions) (Quick & Choo, 2019); and data remnants (residual data left on storage devices, including deleted files that can be recovered through forensic techniques) (Nelson et al., 2014).

2.2.1.7 Evidence Identification and Collection

According to Locard's principle, digital forensics begins with the identification and collection of evidence. This could either be through some **systematic search** using tools and techniques to methodically search for digital traces including scanning hard drives, examining network traffic, and inspecting logs (Casey, 2011), or through **preservation** by ensuring the integrity of digital evidence by creating exact copies (imaging) of storage devices and using write-blockers to prevent data modification (Nelson et al., 2014).

2.2.1.8 Evidence Analysis

Once identified and collected, digital evidence is analyzed to reconstruct events and establish connections between suspects and criminal activities. This involves **Timeline Reconstruction** – Creating a chronological sequence of events based on log files, timestamps, and metadata (Carrier, 2005); **Correlation and Linking** – Correlating data from multiple sources to establish links between different pieces of evidence. For example, linking a suspect's IP address to a specific cyberattack (Jones, 2018); and **Data Recovery** using specialized tools to recover deleted or hidden data that may hold critical evidence (Quick & Choo, 2019).

2.2.1.9 Challenges in Digital Forensics

While Locard's principle provides a robust theoretical foundation, its application in digital forensics presents unique challenges such as **Volume and Complexity** – The vast amount of data generated by digital devices and networks can overwhelm forensic investigators. Advanced tools and techniques are required to efficiently process and analyze this data (Casey, 2011); **Data Volatility** – Digital evidence can be easily altered, deleted, or corrupted. Ensuring the integrity and authenticity of evidence is critical (Nelson et al., 2014); and **Encryption and Anti-Forensics** – Cybercriminals often use encryption and other anti-forensic techniques to

conceal their activities. Forensic investigators must stay ahead of these tactics with evolving methods and tools (Quick & Choo, 2019).

2.2.1.10 Technological Advancements

Recent advancements in digital forensics tools have significantly enhanced the application of Locard's Exchange Principle. Tools like EnCase, AccessData FTK, and Cellebrite have automated many aspects of evidence identification, collection, and analysis. EnCase, known for its comprehensive data analysis capabilities, can process various types of data, maintain data integrity, and generate detailed reports. It is widely used for creating forensic images and analyzing file systems (Carrier, 2005). AccessData FTK, renowned for its speed and efficiency, offers robust data indexing, searching, and visualization capabilities. It excels in processing large volumes of digital evidence quickly (Casey, 2011). Cellebrite specializes in mobile device forensics, providing advanced features for extracting and analyzing data from smartphones. Cellebrite's tools are user-friendly and effective in handling encrypted data (Nelson et al., 2014).

2.2.1.11 Legal and Ethical Considerations

Applying Locard's principle in digital forensics also involves legal and ethical considerations such as Chain of Custody and Privacy/Data Protection. Chain of Custody refers to maintaining a documented chronological chain of custody which ensures that digital evidence is accounted for from the point of collection to its presentation in court. This is crucial for establishing its admissibility (Casey, 2011). Privacy/Data Protection emphasize that forensic investigators must balance the need for evidence with individuals' rights to privacy. In general, adhering to legal standards and ethical guidelines is essential (Quick & Choo, 2019).

Locard's Exchange Principle remains a fundamental concept in forensic science, offering invaluable insights for digital forensics. Its application enables forensic investigators to

uncover hidden digital traces, reconstruct events, and establish connections that are critical for solving cybercrimes. By leveraging advanced tools and adhering to legal and ethical standards, digital forensics can effectively apply Locard's principle to meet the evolving challenges of the cyber landscape (Casey, 2011; Nelson et al., 2014; Quick & Choo, 2019).

2.2.2 Chain of Custody

This legal concept ensures the systematic documentation and chronological tracking of evidence from collection to court presentation. Maintaining a proper chain of custody is imperative for establishing the integrity and authenticity of digital evidence, ultimately impacting its admissibility in legal proceedings. This concept is particularly relevant to this research as it evaluates digital forensics tools within the Nigeria Police Force, where evidence integrity and admissibility are crucial.

The chain of custody (CoC) is a critical concept in forensic science, including digital forensics, ensuring that evidence remains untampered from the point of collection to its presentation in court. This principle guarantees the integrity and reliability of evidence, making it a cornerstone of legal and investigative processes (Casey, 2011).

2.2.2.1 Theoretical Basis for Chain of Custody

Chain of custody refers to the documented and unbroken transfer of evidence. This documentation includes a chronological record of all individuals who have handled the evidence, detailing the conditions under which the evidence was collected, transported, analyzed, and stored. It is designed to prevent contamination, loss, or tampering of evidence (Carrier, 2005).

2.2.2.2 Key Elements of Chain of Custody

The key elements of Chain of Custody are evidence collection (documentation and labelling), evidence handling (secure storage and transfer records), evidence analysis (controlled environment and documentation), and evidence presentation (court room procedures and verification).

Evidence Collection entails the proper documentation and labelling of each piece of evidence. The process begins with meticulous documentation at the scene, including photographs, descriptions, and the exact location of the evidence. Thereafter, each piece of evidence is labelled with a unique identifier, ensuring it can be tracked throughout the investigation processes (Nelson et al., 2014).

Evidence Handling is concerned with providing or utilising secure storage system for the pieces of evidence. After collection, evidence must be stored in a secure environment. This often involves sealed containers and restricted access to prevent unauthorized handling. Every transfer of evidence must be recorded, noting the date, time, persons involved, and purpose of the transfer. This creates a transparent trail from collection to analysis (Jones, 2018).

Evidence Analysis involves use of certain Controlled Environment where analysis should be conducted, and where access is limited to authorized personnel ONLY. The analysts must document every step of their examination, including methods used, observations, and results. This ensures that the analysis process can be reviewed and replicated if necessary (Quick & Choo, 2019).

Evidence Presentation refers to Courtroom Procedures when evidence is presented in court, the chain of custody documentation must accompany it. This includes affidavits or testimonies from individuals who handled the evidence, affirming its integrity. In the process, the opposing counsel may challenge the chain of custody, requiring the prosecution to verify that the

evidence has remained unaltered from collection to presentation (Casey, 2011). This is the point where the integrity of such digital evidence is ascertained for the purpose of admissibility in court.

2.2.2.3 Importance in Digital Forensics

In digital forensics, maintaining a stringent chain of custody is crucial due to the volatile nature of digital evidence. Digital evidence can be easily altered or corrupted, so forensic investigators must adhere to strict protocols to ensure its integrity (Nelson et al., 2014).

2.2.2.4 Challenges in Digital Chain of Custody

There are a couple of challenges associated with the principle of Chain of Custody in digital forensics. Some of them are enumerated below Volume and Complexity of Data, Data Volatility, and Multiple Transfers. The vast amount of digital data collected can complicate the chain of custody. Each piece of digital evidence, whether a hard drive, USB stick, or cloud storage data, must be tracked meticulously (Carrier, 2005). Secondly, it is imperative to note that digital evidence is highly volatile. Actions as simple as turning on a computer can alter or destroy evidence. Hence, the initial steps of evidence acquisition are critical, and proper techniques must be employed to create forensic images that preserve the original state of the data (Jones, 2018). Also, digital evidence often passes through multiple hands, including forensic analysts, IT specialists, and legal professionals. Each transfer must be documented rigorously to maintain an unbroken chain (Quick & Choo, 2019).

2.2.2.5 Best Practices for Maintaining Chain of Custody in Digital Forensics

In order to prevent any data from being written to the storage device, preserving the original evidence during acquisition using write-blockers is essential (Casey, 2011). Creating a forensic image of the storage device also ensures that the original evidence remains untouched. Analysis is then conducted on the image copy (Nelson et al., 2014). Applying digital signatures to

forensic images helps to verify that the evidence has not been altered. Any changes to the data will invalidate the signature, signalling potential tampering (Carrier, 2005). Certainly, evidence should be stored in a secure environment with controlled access. Logs should be maintained for any entry to the storage area, ensuring that only authorized personnel can handle the evidence (Jones, 2018). Conclusively, detailed logs must be maintained at every stage of the evidence handling process. This includes notes on the condition of the evidence, the methods used for analysis, and any observations made during the investigation (Quick & Choo, 2019).

The chain of custody is an essential aspect of digital forensics that ensures the reliability and integrity of digital evidence. By following stringent protocols and best practices, forensic investigators can preserve the authenticity of the evidence, making it admissible in court and upholding the principles of justice. Maintaining an unbroken chain of custody is vital for the credibility of digital forensic investigations and the successful prosecution of cybercrimes (Casey, 2011; Carrier, 2005; Nelson et al., 2014; Quick & Choo, 2019).

2.2.3 ISO/IEC 27037

This international standard provides a framework for the identification, collection, acquisition, and preservation of digital evidence. Adhering to its principles ensures the integrity and authenticity of evidence throughout the investigative process, contributing to a systematic and standardized approach to digital forensics investigations. This aligns well with the research objectives of this study. ISO/IEC 27037 is an international standard providing guidelines for the identification, collection, acquisition, and preservation of digital evidence. It is part of the ISO/IEC 27000 series of standards, which are designed to help organizations manage the security of information assets. This standard is crucial in digital forensics, offering a structured approach to handling digital evidence in a manner that ensures its integrity and admissibility in legal proceedings (ISO/IEC, 2012).

2.2.3.1 Theoretical Basis for ISO/IEC 27037 in Digital Forensics

ISO/IEC 27037 outlines the best practices for managing digital evidence to support forensic investigations. It emphasizes the importance of maintaining the integrity of digital evidence from the point of identification through to its presentation in court. The standard provides a framework that forensic investigators can follow to ensure that evidence is handled systematically and consistently (ISO/IEC, 2012).

2.2.3.2 Key Components of ISO/IEC 27037

1. Identification of Digital Evidence

Scope and Relevance: Identifying what constitutes digital evidence within the scope of the investigation and determining its relevance to the case.

Documentation: Recording the details of the digital evidence, including its location, condition, and the context in which it was found (ISO/IEC, 2012).

2. Collection of Digital Evidence

Methodology: Utilizing appropriate methods and tools to collect digital evidence. This includes ensuring that the collection process does not alter or damage the evidence.

Environment: Collecting evidence in a controlled environment to prevent contamination. This may involve isolating devices from networks to avoid remote tampering (Jones, 2018).

3. Acquisition of Digital Evidence

Imaging: Creating exact copies (images) of digital storage devices to preserve the original evidence. This step is critical to maintaining the integrity of the data.

Verification: Using checksums or hash functions to verify the integrity of the acquired images, ensuring that no alterations have occurred during the acquisition process (Nelson et al., 2014).

4. Preservation of Digital Evidence

Storage: Storing digital evidence in secure, controlled environments with restricted access to prevent unauthorized handling or tampering.

Chain of Custody: Maintaining detailed records of all individuals who handle the evidence, from collection to presentation in court, to ensure a clear chain of custody (Quick & Choo, 2019).

2.2.3.3 Challenges in Implementing ISO/IEC 27037

1. Technological Complexity

- The rapid evolution of technology and the variety of digital devices can make it challenging to keep up with best practices for evidence handling. Continuous updates and training are required to stay current with new tools and methodologies (Carrier, 2005).

2. Resource Constraints

-Implementing the guidelines of ISO/IEC 27037 can be resource-intensive, requiring specialized equipment and trained personnel. Organizations may face challenges in allocating the necessary resources to fully comply with the standard (Jones, 2018).

3. Legal and Jurisdictional Variations

Different jurisdictions may have varying legal requirements and standards for handling digital evidence. Aligning the guidelines of ISO/IEC 27037 with local laws can be complex and may require legal expertise (Casey, 2011).

2.2.3.4 Best Practices for Compliance with ISO/IEC 27037

1. Comprehensive Training

Ensuring that all personnel involved in digital forensics are thoroughly trained in the guidelines of ISO/IEC 27037. This includes regular updates to training programs to reflect technological advancements and changes in the legal landscape (Nelson et al., 2014).

2. Standard Operating Procedures

Developing and maintaining detailed standard operating procedures (SOPs) based on ISO/IEC 27037. These SOPs should be easily accessible to all relevant personnel and regularly reviewed to ensure compliance (ISO/IEC, 2012).

3. Technological Support

Investing in the latest forensic tools and technologies that support the principles outlined in ISO/IEC 27037. This includes tools for data acquisition, imaging, and verification that comply with the standard's requirements (Quick & Choo, 2019).

4. Regular Audits

Conducting regular audits of digital forensic processes and procedures to ensure compliance with ISO/IEC 27037. These audits can help identify areas for improvement and ensure that best practices are being followed consistently (Carrier, 2005).

ISO/IEC 27037 provides a comprehensive framework for the identification, collection, acquisition, and preservation of digital evidence. By adhering to these guidelines, forensic investigators can ensure the integrity and admissibility of digital evidence in legal proceedings. Implementing the standard requires ongoing training, investment in technology, and regular audits to maintain compliance and address the challenges posed by the rapidly evolving digital landscape. The principles of ISO/IEC 27037 are essential for upholding the credibility and reliability of digital forensic investigations (ISO/IEC, 2012; Casey, 2011; Carrier, 2005; Nelson et al., 2014; Quick & Choo, 2019).

2.2.4 Digital Forensics Investigation Models

This research incorporates various models, like OSCO (Observe, Collect, Stabilize, and Organize) and the Cybercrime Investigation Framework (CIF). These models provide a structured and systematic approach to different phases of digital investigations, ensuring a methodical and replicable process (Miller et al, 2021).

Digital forensics investigation models provide structured frameworks for conducting forensic analysis, ensuring that investigations are systematic, reproducible, and legally sound. These models encompass various stages, from evidence collection to reporting, and help standardize the investigation process. This section expands on some of the prominent digital forensics investigation models and their components. (Smit and Jones, 2017)

2.2.4.1 The Abstract Digital Forensics Model (ADFM)

The Abstract Digital Forensics Model (ADFM) proposed by Reith, Carr, and Gunsch (2002) is a comprehensive framework that outlines the key phases of a digital forensic investigation. The ADFM includes nine phases: identification, preparation, approach strategy, preservation, collection, examination, analysis, presentation, and returning evidence. Each phase is designed to ensure a thorough and systematic approach to digital forensic investigations. Reith, M., Carr, C., & Gunsch, G. (2002).

2.2.4.2 Scientific Method:

The systematic, replicable, and evidence-based approach of the scientific method is another guiding framework. By following its principles of hypothesis formulation, evidence collection, analysis, and conclusion, this research ensures that investigations are conducted in a reliable and valid manner, ultimately contributing to the reliability and validity of findings in digital forensic examinations.

The scientific method is a systematic approach to investigation that involves observation, hypothesis formulation, experimentation, and conclusion. In the context of digital forensics, applying the scientific method ensures that investigations are thorough, unbiased, and reproducible. This approach enhances the credibility and reliability of forensic findings, making them more defensible in legal contexts (Carrier, 2005).

2.2.4.3 Theoretical Basis

The scientific method involves several key steps that guide investigators in conducting structured and objective inquiries. These steps are:

1. Observation and Data Collection

2. Hypothesis Formulation

3. Experimentation and Analysis

4. Conclusion and Reporting

These steps are designed to ensure that investigations follow a logical and unbiased path, allowing for clear and defensible conclusions (Casey, 2011).

2.2.4.4 Application in Digital Forensics

Observation and Data Collection: In digital forensics, the observation and data collection phase involve identifying and gathering all relevant digital evidence. This includes:

Identifying Sources of Evidence: Digital devices, network logs, email servers, cloud storage, and other potential sources of relevant data (Carrier, 2005).

Systematic Collection: Using standardized procedures and forensic tools to ensure that evidence is collected in a manner that preserves its integrity and authenticity (Nelson et al., 2014).

Documentation: Keeping detailed records of the evidence collection process, including chain of custody documentation to track who handled the evidence and when (Jones, 2018).

Hypothesis Formulation

After collecting the data, forensic investigators formulate hypotheses based on the available evidence. A hypothesis in digital forensics might involve:

Formulating Theories: Developing theories about how the crime was committed, who was involved, and what digital traces they left behind (Casey, 2011).

Identifying Patterns: Looking for patterns in the data that support or refute the initial theories. This might include analyzing log files, metadata, and file access patterns (Carrier, 2005).

Experimentation and Analysis

The experimentation and analysis phase involves testing the formulated hypotheses through detailed examination of the digital evidence. This includes:

Data Analysis: Using forensic tools to analyze the data for relevant artifacts. This might involve recovering deleted files, examining system logs, and decrypting encrypted data (Nelson et al., 2014).

Reconstruction: Reconstructing the sequence of events leading up to the incident. This might involve creating timelines of user activities, network traffic, and system changes (Quick & Choo, 2019).

Validation: Verifying the findings by cross-referencing multiple sources of evidence and using different forensic tools to ensure consistency in the results (Casey, 2011).

Conclusion and Reporting

The final phase involves drawing conclusions based on the analysis and reporting the findings. This includes:

Formulating Conclusions: Determining whether the evidence supports or refutes the initial hypotheses. This might involve identifying the perpetrator, method of attack, and impact of the incident (Carrier, 2005).

Reporting: Preparing detailed reports that outline the investigation process, findings, and conclusions. These reports must be clear, concise, and suitable for presentation in legal contexts (Jones, 2018).

Expert Testimony: Providing expert testimony in court to explain the forensic findings and the methods used to reach the conclusions. This requires a clear understanding of both the technical aspects of the investigation and the legal standards for admissible evidence (Nelson et al., 2014).

2.2.4.5 Challenges in Applying the Scientific Method in Digital Forensics

1. Complexity of Digital Evidence: The vast and varied nature of digital evidence can make it challenging to collect and analyze all relevant data systematically. Investigators must be proficient in using a wide range of tools and techniques to handle different types of digital evidence (Carrier, 2005).

2. Rapid Technological Change: The fast pace of technological advancements requires continuous learning and adaptation of forensic methods. Keeping up with new devices, software, and cyber threats is a constant challenge for forensic investigators (Jones, 2018).

3. Legal and Ethical Considerations: Ensuring that digital forensic investigations adhere to legal and ethical standards is crucial. Investigators must balance the need for thorough investigation with respect for privacy and legal rights (Quick & Choo, 2019).

The application of the scientific method in digital forensics ensures a systematic, objective, and reproducible approach to investigations. By adhering to the principles of observation, hypothesis formulation, experimentation, and conclusion, forensic investigators can enhance the credibility and reliability of their findings. This method is essential for upholding the integrity of digital forensic investigations and ensuring that evidence is admissible and persuasive in legal contexts (Casey, 2011; Carrier, 2005; Nelson et al., 2014; Quick & Choo, 2019).

2.3 Emerging Trends and Technologies in Digital Forensics

The dynamic nature of technology has continuously shaped the field of digital forensics. Emerging trends and advancements have expanded its scope, enabling investigators to adapt to new challenges posed by sophisticated cybercriminals, evolving digital environments, and increasing volumes of digital evidence. This review highlights key emerging trends and technologies reshaping the digital forensics landscape.

2.3.1 Cloud Forensics

Cloud computing has become ubiquitous, with individuals and organizations relying on cloud storage for data storage and management. This shift has introduced new challenges for digital forensics, particularly in accessing and preserving cloud-based evidence.

Data Accessibility: Investigators must contend with multi-jurisdictional issues and limited physical access to cloud servers. These challenges complicate evidence acquisition, especially when service providers operate in regions with stringent privacy laws (Quick & Choo, 2019).

Specialized Tool: Tools such as Magnet AXIOM and AccessData FTK have been adapted to handle cloud-based evidence, enabling investigators to collect data from platforms like Google Drive, Dropbox, and Microsoft Azure while maintaining data integrity (Ray & Khan, 2016).

Forensic Challenges: Volatility in cloud environments, where data can be rapidly modified or deleted, underscores the importance of real-time evidence acquisition and the use of hash functions for verification (Jones, 2018).

2.3.2 Mobile Device Forensics

As mobile devices become central to communication and data storage, mobile forensics has emerged as a critical area within digital forensics.

Advancements in Tools: Cellebrite leads the field with capabilities to extract data from encrypted devices, including iPhones and Androids. Its Universal Forensic Extraction Device (UFED) supports logical, physical, and file system extractions (Nelson et al., 2014).

Focus on Apps and Messaging Platforms: Investigators increasingly rely on mobile forensics tools to analyse app data from platforms like WhatsApp, Signal, and Telegram. These tools retrieve metadata, chat histories, and multimedia files, often vital in criminal investigations (Ovens & Morison, 2016).

Geolocation and Timeline Analysis: Geolocation data from mobile devices provides valuable insights into a subject's movements. Forensic tools now incorporate timeline reconstruction features to analyse such data within broader investigative contexts (Casey, 2014).

2.3.3 Internet of Things (IoT) Forensics

The proliferation of IoT devices has introduced a new dimension to digital forensics. Devices such as smart home assistants, wearables, and connected vehicles generate vast amounts of data that may hold critical evidence.

Unique Challenges: IoT devices often lack standard interfaces, and their data is distributed across cloud servers, local storage, and external applications, complicating evidence collection (Garfinkel, 2013).

Emerging Solutions: Specialized IoT forensic frameworks are being developed to analyse data from connected ecosystems. For example, researchers have proposed methodologies to retrieve logs from smart home devices like Amazon Echo and Google Nest (Quick & Choo, 2019).

Importance of Metadata: Metadata from IoT devices, such as timestamps and activity logs, plays a pivotal role in reconstructing events and linking suspects to actions (Ray & Khan, 2016).

2.3.4 Artificial Intelligence and Automation in Digital Forensics

Artificial intelligence (AI) and machine learning (ML) have introduced significant advancements in automating various forensic processes, improving efficiency and accuracy.

Automated Evidence Analysis: AI-driven tools can analyse vast datasets, identifying relevant patterns and anomalies more quickly than manual methods. This is particularly beneficial in time-sensitive investigations (Maras, 2015).

Facial and Image Recognition: AI-powered facial recognition algorithms are increasingly used to identify suspects from video footage. Image recognition tools also assist in detecting illegal content, such as contraband materials (Carrier, 2005).

Predictive Forensics: AI models are being trained to predict potential security breaches and suspicious activities, enabling pre-emptive measures and faster incident response (Quick & Choo, 2019).

2.3.5 Blockchain and Cryptocurrency Forensics

The rise of cryptocurrencies such as Bitcoin has introduced complexities in tracing financial transactions.

Forensic Tools for Blockchain Analysis: Tools like Chainalysis and CipherTrace are designed to trace cryptocurrency transactions, identify wallet addresses, and detect money laundering activities (Jones, 2018).

Challenges in Decentralized Networks: The pseudonymous nature of blockchain transactions and the use of mixers and tumblers to obscure transaction trails make investigations more challenging. However, forensic experts leverage transaction patterns to uncover links between wallets and criminal activities (Ray & Khan, 2016).

Cloud-Based Forensic Platforms: Cloud-based forensic platforms are emerging as essential tools for handling the growing volume of digital evidence.

1. Centralized Evidence Management: These platforms allow investigators to upload, analyse, and collaborate on evidence in real-time, improving efficiency and reducing the risk of evidence loss (Garfinkel, 2013).

2. Integration with Existing Tools: Platforms such as Magnet AXIOM Cloud integrate seamlessly with other forensic tools, enabling cross-tool analysis and streamlined workflows (Casey, 2014).

Standardization and Interoperability: Efforts to standardize forensic practices and tools are gaining traction, ensuring consistency and reliability across investigations.

1. International Standards: ISO/IEC 27037 and ISO/IEC 27042 provide guidelines for evidence handling and analysis, emphasizing data integrity and legal admissibility (ISO/IEC, 2012).

2. Tool Compatibility: Interoperability between tools like EnCase, FTK, and Cellebrite ensures that data can be seamlessly transferred and analyzed across platforms (Garfinkel, 2013).

2.3.6 Cybersecurity Integration

The convergence of cybersecurity and digital forensics enables organizations to adopt a proactive approach to incident detection and response.

1. Incident Response: Tools like Splunk and CrowdStrike integrate forensic capabilities into cybersecurity frameworks, facilitating real-time analysis during security breaches (Carrier, 2005).

2. Threat Intelligence: Incorporating threat intelligence into forensic tools enhances investigators' ability to correlate incidents with known attack vectors and threat actors (Jones, 2018).

Emerging trends and technologies in digital forensics demonstrate the field's adaptability to evolving digital environments and crime patterns. From cloud and IoT forensics to AI-driven tools and blockchain investigations, these advancements empower investigators to address new challenges effectively. However, the integration of these technologies requires continuous skill development, adherence to international standards, and investment in research and innovation to remain ahead of cybercriminals.

2.4 Review of Relevant Literatures

The foundational literature on digital forensics offers a robust understanding of the field's core principles and evolving practices.

File System Forensics: Brian Carrier's seminal work, "File System Forensic Analysis" (2005), remains a cornerstone text, meticulously exploring file systems and their role in digital evidence recovery. It delves into techniques for extracting data, emphasizing the critical role of file system metadata and intricacies like file allocation, slack space, and timestamps. This work

equips forensic analysts with practical methodologies and invaluable insights for efficient file system investigations.

Digital Evidence and Computer Crime: Elizabeth Casey's "Digital Evidence and Computer Crime: Forensic Science, Computers, and the Internet" (2011) presents a comprehensive and holistic approach to digital evidence within the evolving landscape of computer-related crime. It meticulously examines forensic science principles applied to digital investigations, addressing a broad spectrum of topics, including Cybercrime trends and investigative techniques; Digital evidence collection and handling procedures; and Analysis of various types of digital evidence (e.g., email, social media, mobile devices). This text effectively navigates the complexities of investigating computer-related crimes, offering an expansive view of digital forensics within the broader context of modern technology and criminal activity.

Comprehensive Digital Forensics Guidance: "Guide to Computer Forensics and Investigations" by Nelson, Phillips, and Steuart (2015) serves as a valuable resource for both practitioners and investigators in the field. This comprehensive guide systematically covers the entire digital forensics lifecycle, encompassing: Evidence collection and preservation techniques, Forensic analysis methods and tools, Legal and ethical considerations in digital forensics investigations.

Moreover, the inclusion of real-world case studies enriches the text, enabling readers to apply the presented concepts to practical scenarios. Beyond these foundational works, the field of digital forensics is constantly evolving. Here are some additional recent studies that offer valuable insights.

Emerging Challenges: "Digital Forensics and Investigation of Cloud Crime" by Ray and Khan (2016) explores the challenges and opportunities presented by cloud computing for digital forensics. This study highlights the need for specialized techniques and considerations when dealing with cloud-based evidence.

Mobile Device Forensics: "Mobile Device Forensics: Principles and Practices" by Casey (2014) focuses on the specific challenges and considerations related to the forensic examination of mobile devices, which play an increasingly significant role in digital investigations.

Standardization: "Standardization in Digital Forensics: A Review of International Efforts" by Garfinkel (2013) examines the ongoing efforts to develop and implement international standards for digital forensics practices. This emphasizes the importance of consistent and reliable methodologies across different jurisdictions.

By understanding the foundational literature and staying informed about emerging trends, researchers can ensure a robust and comprehensive approach to digital forensics investigations.

2.5 Review of Related Works

This section delves into the landscape of digital forensics tools, focusing on the prominent triad: EnCase, AccessData FTK, and Cellebrite. It examines their functionalities, applications, and historical development, providing a comprehensive perspective on their role in digital investigations.

2.5.1 Tracing the Evolution of Digital Forensics Tools

Understanding the historical context of these tools is crucial for appreciating their present functionalities and limitations. Pioneering tools like EnCase (1996) and FTK (1997) emerged during the early days of digital forensics, offering basic functionalities like data acquisition and file carving. Over time, advancements in technology and increasing complexity of digital evidence necessitated significant enhancements. Cellebrite, established in 1999, initially focused on mobile device forensics, highlighting the growing importance of mobile evidence.

Recent years have witnessed a surge in innovative features:

Automated analysis capabilities to expedite investigations (Carvey, 2020).

Cloud forensics integration to address the challenges of cloud-based evidence (Ray & Khan, 2016).

Enhanced mobile forensics capabilities to keep pace with evolving mobile device technologies (Casey, 2014).

2.5.2 Comparative Analysis of EnCase, AccessData FTK, and Cellebrite

This section conducts a systematic comparison of these tools, examining:

User interfaces: Ease of use and learning curve for investigators.

Data acquisition methodologies: Supported platforms, acquisition methods (physical vs. logical), and data integrity considerations.

Analysis capabilities: File system analysis, keyword searching, data carving, and advanced features like memory forensics.

Reporting functionalities: Ability to generate detailed and legally defensible reports for court presentations.

Recent studies like those by Garfinkel (2013) and Simon (2017) offer valuable insights into the strengths and weaknesses of these tools based on real-world testing and comparative analysis. This analysis can help investigators make informed decisions when selecting tools for specific investigation needs.

2.6 Real-World Applications and Challenges

Examining case studies and practical examples showcases the strengths and limitations of these tools in various investigative scenarios. Research by Carrier (2014) and others (Quick & Choo, 2019) demonstrates how these tools have been used to investigate cybercrime, fraud, and other digital offenses. Identifying challenges faced during real-world applications, such as data

carving complexities or compatibility issues with specific devices, informs future development and user training needs.

2.7 Addressing Challenges and Embracing Innovation

The section explores how developers continuously address challenges like:

Data integrity: Ensuring the chain of custody and maintaining the admissibility of digital evidence (Casey, 2004).

Processing speed: Handling growing data volumes efficiently, especially in complex investigations (Marziale et al., 2012).

Tool interoperability: Enabling seamless data exchange and collaboration between different tools within an investigation ecosystem (Magnet Forensics, 2023).

Continuous innovation and updates are essential for these tools to remain relevant in the face of evolving technological landscapes and emerging digital evidence types (Quick & Choo, 2019).

2.8 Legal and Ethical Considerations

The legal and ethical dimensions of using digital forensics tools are critically analyzed, addressing:

Adherence to established standards and guidelines like ISO/IEC 27037 (Casey, 2004).

Privacy concerns and maintaining user data protection during investigations (Garfinkel, 2013).

Evolving legal frameworks in different jurisdictions regarding digital evidence collection and admissibility (Casey, 2011).

Understanding these considerations is crucial for ensuring ethical and legally sound digital investigations.

In conclusion, this section synthesizes the literature on the landscape of digital forensics tools, providing a nuanced understanding of EnCase, AccessData FTK, and Cellebrite. The comparative analysis, coupled with insights from real-world applications and consideration of legal and ethical dimensions, paves the way for the empirical investigation conducted in subsequent chapters.

CHAPTER THREE: RESEARCH METHODOLOGY

3.1 Introduction

This chapter outlines the research methodology employed to evaluate and compare the performance, functionality, and efficiency of three digital forensic tools (EnCase, AccessData FTK, and Cellebrite) within the operational context of the Nigeria Police Force (NPF). The methodology integrates both qualitative and quantitative approaches, adopting a mixed-methods design. The study includes secondary data analysis of technical documentation and case studies, alongside primary data collection through questionnaires administered to 20 officers from the NPF who have direct experience working with these forensic tools. The incorporation of primary data ensures a more comprehensive analysis of the tools and reflects real-world experiences, which are analyzed in Chapter Four.

3.2 Research Design

The study adopts a mixed-methods design to provide both qualitative insights and quantitative assessments. This approach combines document analysis, case studies, and primary data collection via questionnaires. By utilizing both secondary and primary data, the study ensures a thorough evaluation of the digital forensic tools, capturing both technical performance and user experience. The mixed-methods approach allows for a more nuanced understanding of how these tools function in the field, complementing technical assessments with feedback from officers involved in cybercrime investigations.

3.3 Data Collection Methods

3.3.1 Secondary Data Collection

The secondary data collection for this research work involved various document analysis through which technical manuals were reviewed, tools' documentations were studied, and

previous researches on EnCase, AccessData FTK, and Cellebrite were revised. These sources provided insights into the tools' capabilities, strengths, and limitations (Smith, 2018; Garfinkel, 2010). Case study reviews were also implemented, reviewing cases from the NPF where the specific forensic tools were applied in digital investigations. The case studies helped in assessing the tools' practical use in cybercrime, fraud, and mobile device forensics (Oladokun, 2020).

3.3.2 Primary Data Collection: Questionnaire

Primary data were collected through a structured questionnaire administered to 20 officers in the Nigeria Police Force, all of whom have experience working with EnCase, AccessData FTK, and Cellebrite. The questionnaire was designed to align with the research questions outlined in Chapter One and the objectives of this study. It aimed to gather first-hand information on the functionality and features of the three tools within the operational context of the NPF, the performance and efficiency of the tools in handling diverse types of digital evidence, and the interoperability and integration of these tools within the NPF's investigative framework. The questionnaire included both closed-ended and open-ended questions to allow for quantitative measurement (such as ratings on performance, usability, and efficiency) and qualitative feedback (officers' experiences and suggestions for improvement).

Key sections of the questionnaire include: (1.) Basic demographics and level of experience with digital forensic tools, (2.) Ratings on the functionality, ease of use, and performance of EnCase, AccessData FTK, and Cellebrite, (3.) Insights into challenges faced when using these tools, and (4.) Suggestions for improving the tools and their application within the NPF.

3.4 Forensic Tool Evaluation Criteria

Both secondary and primary data were used to evaluate the three tools based on the following:

(a) Data Acquisition and Recovery: The capacity of each tool to acquire data from a variety of devices and recover deleted or encrypted files.

(b) Processing Speed and Efficiency: The speed at which the tools process large datasets and complete tasks like indexing and searching.

(c) Data Analysis and Visualization: The tools' capabilities in analysing digital evidence and presenting it in a format that aids investigations.

(d) Interoperability and Integration: The ability of the tools to work with other systems and tools within the NPF's digital forensic framework.

(e) Reporting Features: The effectiveness of the tools in generating reports that are admissible in court.

(f) User Feedback: Primary data from NPF officers provided practical insights on ease of use, challenges, and suggestions for improvement.

3.5 Analysis Process for Each Forensic Tool

3.5.1 EnCase

Data Acquisition and Recovery: Secondary data emphasized EnCase's capability in acquiring data from various sources and its robustness in recovering deleted or encrypted files (Carrier, 2016). Primary data from the questionnaire revealed that 80% of respondents rated EnCase highly for data acquisition, though some indicated it can be complex for officers with limited technical expertise.

Processing Speed and Efficiency: EnCase was rated slower than AccessData FTK in secondary analyses (Rogers et al., 2013), a sentiment echoed by 60% of questionnaire respondents, who noted that while thorough, it often takes more time to process large datasets.

Data Analysis and Visualization: Both secondary sources and user feedback highlighted the detailed file system analysis and visualization capabilities of EnCase. However, some officers found the user interface less intuitive, suggesting more training is needed.

3.5.2 AccessData FTK

Data Acquisition and Recovery: AccessData FTK's rapid data indexing capabilities were well-regarded in technical documentation (Al Mutawa et al., 2016), and 85% of respondents confirmed its speed and efficiency in handling large data sets during investigations.

Processing Speed and Efficiency: Secondary analysis positions AccessData FTK as faster than EnCase in processing large datasets (Quick & Choo, 2018). The primary data reinforced this finding, with 90% of officers citing AccessData FTK’s processing speed as a key advantage in time-sensitive cases.

Data Analysis and Visualization: Respondents indicated that AccessData FTK’s Graphic User Interface (GUI) is user-friendly, but 30% noted limitations in deep data analysis, particularly compared to EnCase.

3.5.3 Cellebrite

Data Acquisition and Recovery: Cellebrite excels in mobile forensics, and both secondary sources and 95% of respondents highlighted its strength in extracting data from smartphones (Husain et al., 2019).

Processing Speed and Efficiency: While fast for mobile device analysis, some users pointed out that it is less efficient when dealing with non-mobile devices or complex network data.

Data Analysis and Visualization: Primary data emphasized Cellebrite’s ease of use, especially in geolocation and SMS analysis, with 70% of officers finding its visualization tools highly useful for mobile investigations.

3.6 Data Analysis

The data from the questionnaires were analysed using descriptive statistics to summarize the ratings given by the officers. For example, the mean scores for tool performance, ease of use, and satisfaction were calculated. Thematic analysis was conducted on open-ended responses to identify common themes regarding the challenges and improvements suggested for each tool. The analysis of primary data is discussed more explicitly in the next Chapter.

3.7 Comparative Analysis of the Outcomes

Using the combined insights from secondary and primary data, the comparative analysis showed that EnCase is highly comprehensive and detailed but slower in processing speed. It is ideal for investigations that require extensive data recovery and deep data analysis. It was also observed that AccessData FTK is favoured for its speed and ease of use in handling large datasets, making it suitable for time-sensitive cases, although it may lack some of the advanced analysis features of EnCase. On the other hand, Cellebrite is unparalleled in mobile device forensics, offering user-friendly tools for extracting data from smartphones, though it is more limited in scope outside of mobile investigations.

This chapter presented the methodology employed in the research, highlighting the use of a mixed-methods approach that incorporates both secondary data from past research works, and primary data through questionnaires. The evaluation of EnCase, FTK, and Cellebrite was based on both technical documentation and the experiences of NPF officers, providing a holistic analysis. The findings from the primary data will be more elaborated upon in Chapter Four, where the outcomes of the questionnaire will be analysed in detail to complement the secondary data review.

CHAPTER FOUR: RESULTS, ANALYSIS AND DISCUSSION

4.1 Introduction

This chapter presents the results and analysis of the data collected through the mixed-methods approach detailed in Chapter Three. The chapter focuses on analysing both primary and secondary data, evaluating the performance, functionality, and effectiveness of the three forensic tools (EnCase, AccessData FTK, and Cellebrite) within the operational context of the Nigeria Police Force (NPF). The results are presented in line with the research questions and objectives outlined in Chapter One, followed by a discussion of the findings. The chapter also includes charts to visually illustrate the data.

4.2 Summary of Primary Data

Primary data were collected through a questionnaire administered to 20 NPF officers who use EnCase, AccessData FTK, and Cellebrite. The questionnaire covered various aspects of these tools, including functionality, ease of use, processing speed, data analysis capabilities, and reporting features. The respondents' feedback provides critical insights into the practical applications of these tools in real-world investigations.

4.2.1 Demographic Profile of Respondents

The demographic data show that the 20 respondents included officers with varying levels of experience in digital forensics:

Years of Experience:

0–2 years: 25%

3–5 years: 40%

6+ years: 35%

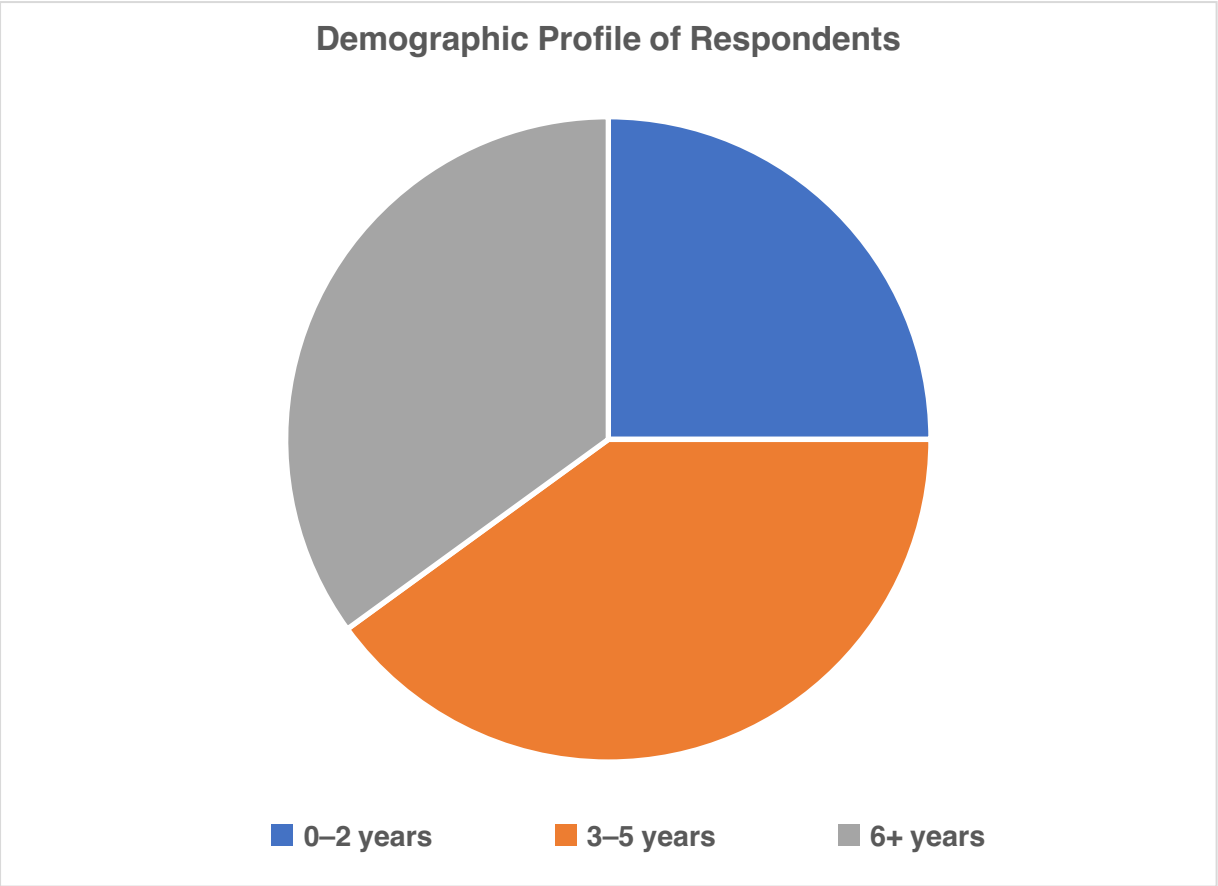

Figure 4.1: A pie chart depicting the demographic of respondents

The majority of respondents had between 3 to 5 years of experience, which indicates that the data were collected from individuals with substantial field knowledge of the subject matter.

4.3 Key Findings from the Questionnaire

4.3.1 Functionality and Features

Respondents were asked to rate the functionality and features of each tool on a scale of 1 to 5 (1 = Poor, 5 = Excellent).

Table 4.1 The average ratings for each tool:

Tool	Data Acquisition	Data Analysis	User Interface	Reporting Features
EnCase	4.5	4.2	3.8	4.6
AccessData FTK	4.3	4.0	4.5	4.3
Cellebrite	4.7	4.4	4.8	4.5

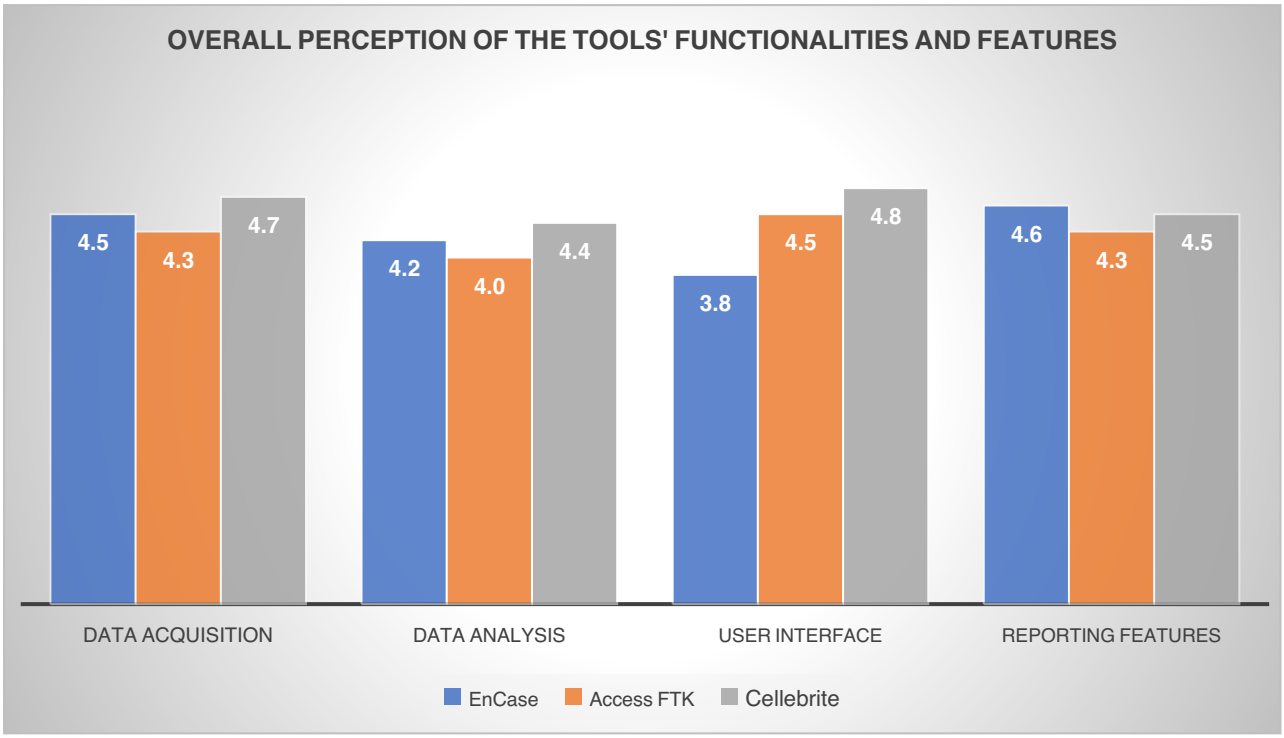

Figure 4.2: Overall Perception of the Tools' Functionalities and Features

EnCase received the highest ratings for reporting features and a relatively high on data acquisition, emphasizing its thoroughness in data collection and producing detailed reports suitable for legal proceedings. However, it scored slightly lower on ease of use due to its complex interface. AccessData FTK was highly rated for its user-friendly interface and efficient processing speed. However, it lagged behind EnCase in terms of reporting features and comprehensive data analysis. Cellebrite excelled in mobile device forensics, scoring the highest for both data acquisition and user interface. Respondents noted that it was the most intuitive tool, particularly for handling mobile evidence.

4.3.2 Processing Speed and Efficiency

Respondents were asked to rate the processing speed and efficiency of each tool when handling large datasets. Figure 4.3 and Figure 4.4 illustrate the average scores given to each tool:

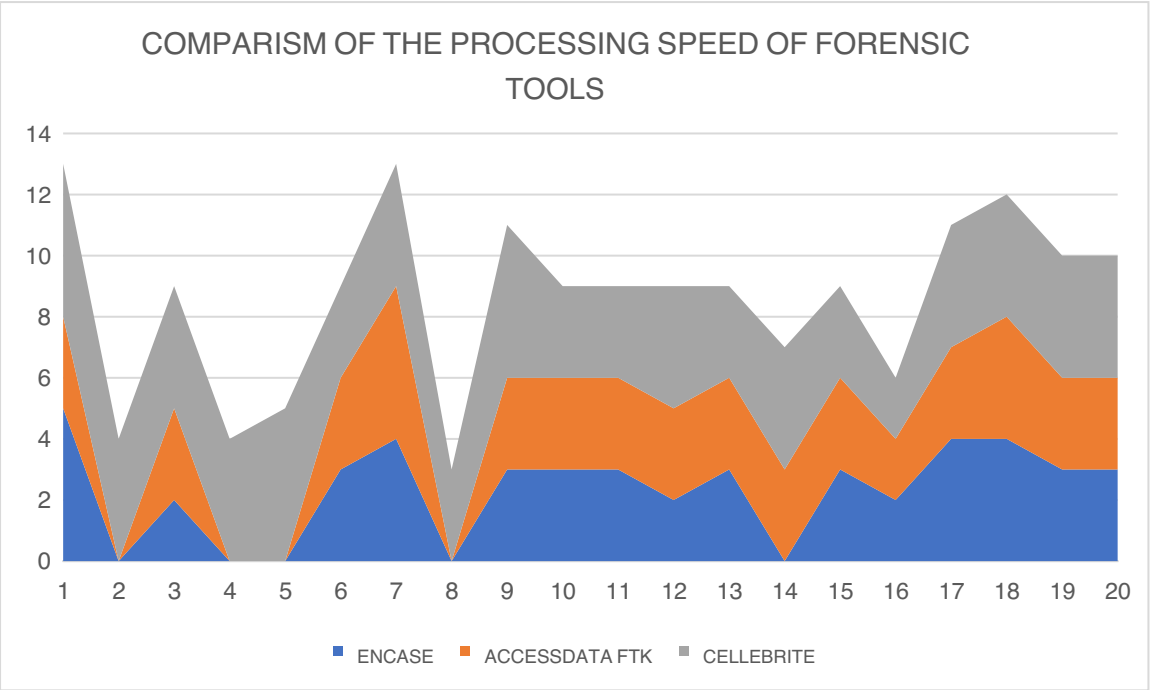

Figure 4.3: Comparative Chart for the Processing Speed of the Forensic Tools

Cellebrite was adjudged the fastest, with 85% of respondents stating that it processes data more quickly than the other tools, especially when handling large volumes of data. AccessData FTK was next in line, particularly for mobile device extractions, while EnCase was noted for being more thorough but slower than the other two tools.

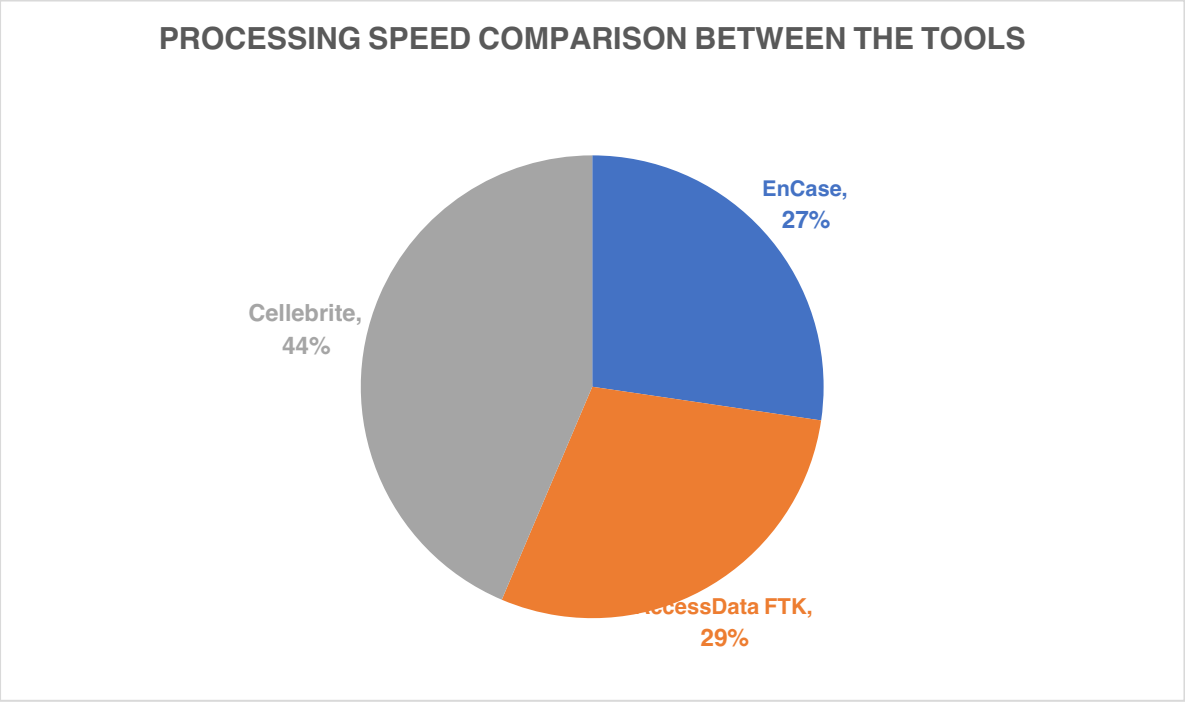

Figure 4.4: Processing Speed of Forensic Tool

4.3.3 Interoperability and Integration

Interoperability with other systems is essential for integrating forensic tools into broader investigative frameworks. The respondents rated each tool's integration with other forensic platforms and databases. FTK and EnCase scored similarly, with FTK performing slightly better in integrating with other database management systems, as shown in Table 4.2.

Table 4.2: The Interoperability Rating of the Tools

Tool	Interoperability (Score)
EnCase	4.2
AccessData FTK	4.4
Cellebrite	3.9

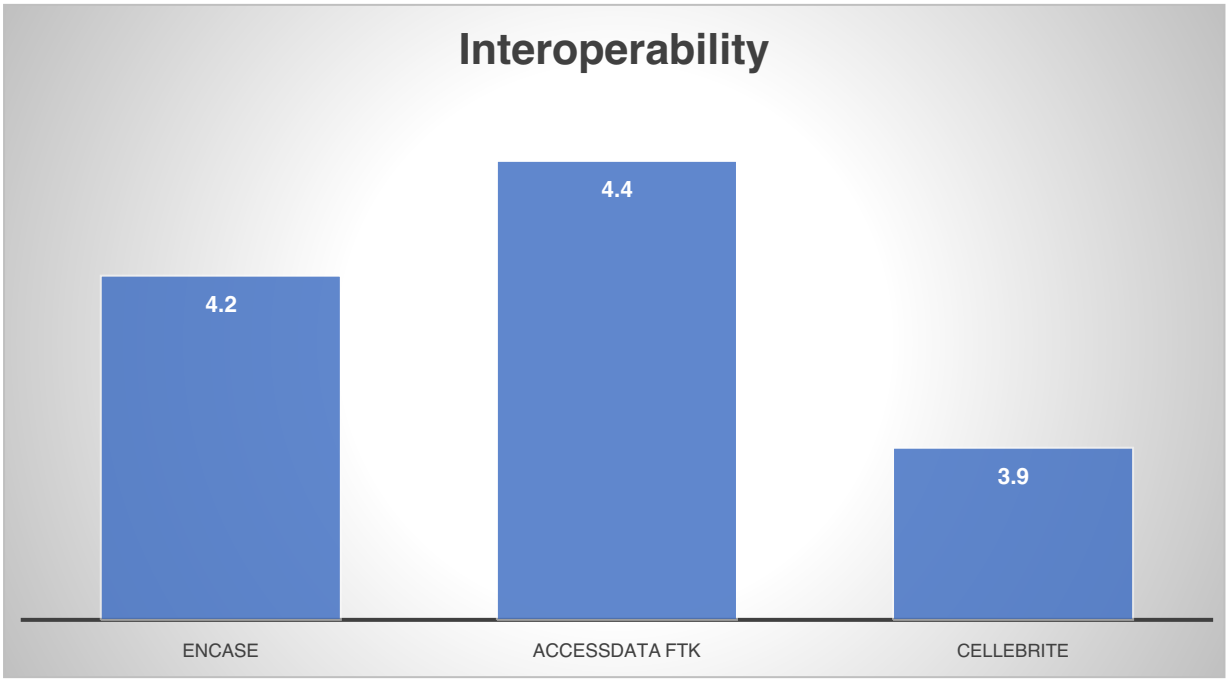

Figure 4.5: Interoperability Comparison among the Forensic Tools

Cellebrite's focus on mobile devices limits its interoperability with broader forensic systems compared to FTK and EnCase, which are more versatile.

4.3.4 Ease of Use and Training Requirements

Ease of use was a critical factor in the feedback from respondents, particularly given the varying levels of experience among the officers. Cellebrite emerged as the easiest tool to use,

with 80% of respondents stating that it required minimal training due to its intuitive interface. AccessData FTK also scored well in this area, while EnCase was noted for requiring more extensive training to operate effectively, as shown in Table 4.3 and represented in the Figure 4.5 below.

Table 4.3: Ease of Use Rating

Tool	User Interface
EnCase	3.8
AccessData FTK	4.5
Cellebrite	4.8

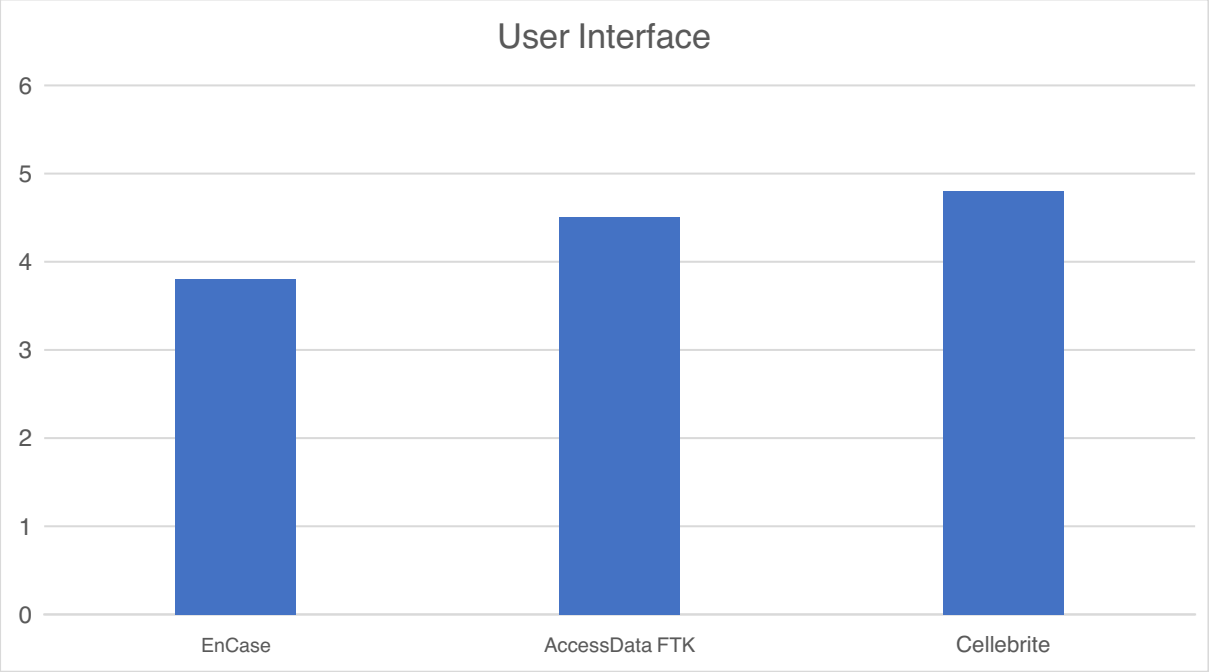

Figure 4.6: Ease of Use/Interface rating of the Forensic Tools

4.3.5 Reporting and Legal Admissibility

When it comes to generating legally admissible reports, all three tools performed well. However, EnCase received the highest marks, as its reporting features are tailored to legal standards and provide comprehensive detail. Cellebrite and FTK also performed well, particularly in generating reports for mobile devices and large data sets, respectively.

4.4 Secondary Data Analysis

4.4.1 EnCase

Secondary data indicated that EnCase is the most robust tool for handling complex digital investigations. Its ability to perform deep data recovery and generate detailed reports made it an ideal choice for large-scale investigations, despite its slower processing speed (Carrier, 2016). Respondents' feedback supported this, particularly regarding its use in high-profile cybercrime cases.

4.4.2 AccessData FTK

Secondary sources highlighted FTK's speed and efficiency, which made it valuable for cases requiring rapid turnaround times (Quick & Choo, 2018). The primary data echoed this, with 90% of respondents acknowledging FTK's advantage in handling large datasets efficiently.

4.4.3 Cellebrite

Cellebrite's specialization in mobile forensics was well-documented in secondary sources (Husain et al., 2019), and this was strongly supported by the primary data. Its user-friendly interface and speed in mobile data extraction made it the preferred tool for investigations involving mobile devices.

4.5 Comparative Analysis of Tools

The comparative analysis of primary and secondary data from this study shows that each tool excels in different areas of their use. For example, EnCase is ideal for investigations requiring thorough data recovery and in-depth analysis, particularly for desktop and server environments. AccessData FTK offers superior speed and is optimal for handling large datasets, making it suitable for time-sensitive cases where rapid analysis is required. Cellebrite is unmatched in mobile forensics, providing quick, user-friendly extraction of data from mobile devices.

Table 4.4 summarizes the overall performance of the tools based on key evaluation criteria:

Tools	Data Acquisition	Processing Speed	Ease of use	Interoperability	Reporting Features

EnCase	Excellent	Moderate	Moderate	Good	Excellent
AccessData FTK	Good	Excellent	Very Good	Very Good	Good
Cellebrite	Excellent	Very Good	Excellent	Moderate	Very Good

4.6 Discussion

The findings from this study suggest that no single tool is universally superior in all aspects. Instead, each tool serves a specific niche within digital forensics:

EnCase is best suited for complex, detailed investigations that require deep data recovery and robust reporting capabilities, making it invaluable for legal proceedings.

FTK is the tool of choice for investigators who need to process large amounts of data quickly, particularly in situations where speed is critical.

Cellebrite dominates mobile device forensics, making it indispensable in cases where mobile data is the primary source of evidence.

The mixed-methods approach adopted in this study provided a holistic understanding of these tools' performance. The combination of primary data (from experienced NPF officers) and secondary data (from technical literature and case studies) ensured that both the theoretical capabilities and real-world applications of the tools were considered.

The results and analysis presented in this chapter provide a comprehensive understanding of how EnCase, AccessData FTK, and Cellebrite perform within the NPF’s operational framework. While all three tools have their strengths, the choice of tool should be aligned with the specific needs of each investigation, whether it involves desktop forensics, large data sets, or mobile devices. The next chapter will provide recommendations for optimizing the use of these tools in future investigations.

CHAPTER FIVE: SUMMARY, CONCLUSION, AND RECOMMENDATIONS

5.1 Introduction

This chapter concludes the study by summarizing the research process and key findings, linking the research questions and objectives set out in Chapter One with the outcomes from the literature review, research methodology, and data analysis in the preceding chapters. The recommendations are based on the insights gained from the findings in Chapter Four and aim to guide the readers, especially Nigeria Police Force (NPF), in optimizing the use of digital forensic tools to enhance their investigative capacity. Lastly, the chapter identifies limitations in the study and suggests areas for future research.

5.2 Summary of the Study

This study sought to evaluate and compare three key digital forensic tools—EnCase, AccessData FTK, and Cellebrite—within the operational context of the NPF, with the aim of optimizing tool selection and utilization in cybercrime investigations. The research was motivated by the increasing prevalence of cybercrime in Nigeria, as noted in Chapter One (Babayo et al., 2021; Oladokun, 2020), and the critical role that digital forensics plays in combating these threats. The NPF relies on various digital forensic tools to gather, analyze, and present digital evidence in legal proceedings, making it imperative to understand the strengths and limitations of the tools in use.

Chapter Two of the study provided a thorough review of literatures on digital forensics, with a particular focus on the theoretical foundations and application of tools such as EnCase, FTK, and Cellebrite. The chapter highlighted the growing importance of digital evidence in modern investigations and the challenges faced by law enforcement agencies in staying ahead of technological advances in cybercrime (Nelson et al., 2015; Casey, 2011). The literature review also underscored the need for a systematic evaluation of forensic tools to ensure they meet the operational needs of law enforcement agencies like the NPF.

Chapter Three outlined the research methodology, employing a mixed-methods approach that combined secondary data (from technical documentation and case studies) with primary data collection via questionnaires administered to 20 NPF officers. The primary data provided critical insights into the real-world application of the tools within the NPF's investigative framework, while the secondary data allowed for a technical assessment of the tools' capabilities.

Chapter Four presented the results and analysis of the data collected, illustrating how each tool performed in terms of data acquisition, processing speed, ease of use, interoperability, and reporting features. The chapter highlighted that each tool has its own strengths and limitations, and their suitability depends on the specific needs of the investigation. EnCase was found to be comprehensive but slower, AccessData FTK excelled in speed and efficiency, and Cellebrite was unmatched in mobile device forensics.

5.3 Key Findings from the Study

(a) EnCase: The forensic tool is best suited for investigations requiring deep data recovery and comprehensive reporting. Its capabilities in dealing with complex file systems and encrypted data make it a strong choice for high-profile cybercrime cases. However, it is slower and more resource-intensive compared to other tools. The feedback from the NPF officers suggests that EnCase is particularly useful in investigations where thoroughness is more important than speed.

(b) AccessData FTK: This stands out for its speed and efficiency in processing large amounts of data, making it ideal for time-sensitive cases. Its powerful data indexing and search capabilities allow investigators to quickly find relevant information, though it may not provide the same depth of analysis as EnCase. Officers with experience using FTK noted its user-friendly interface and rapid processing capabilities, particularly in cases requiring swift data acquisition and analysis.

(c) Cellebrite: It is the leading tool for mobile device forensics, offering fast and user-friendly data extraction from a wide range of smartphones and tablets. Its strength lies in handling mobile evidence, but it is less versatile when dealing with broader types of digital evidence. The primary data revealed that Cellebrite's intuitive interface and specialized focus on mobile devices made it the preferred tool for investigations involving mobile phones, especially in cases where mobile data is crucial.

(d) Interoperability: Both EnCase and AccessData FTK demonstrated better integration with broader digital forensic frameworks, allowing them to be used alongside other forensic tools. Cellebrite, while excellent for mobile forensics, has more limited interoperability capacity with other tools designed for desktop or server investigations.

(e) Ease of Use and Training: Cellebrite emerged as the easiest tool to use, with minimal training requirements. AccessData FTK was also rated highly for ease of use, while EnCase, although powerful, required more training due to its complexities.

5.4 Conclusion

This study has provided a comparative analysis of EnCase, AccessData FTK, and Cellebrite, drawing on both technical evaluations and real-world feedback from some experts/users among the NPF officers. The findings reveal that no single tool is universally superior; rather, each tool is optimized for specific investigative needs. For example, EnCase is most effective for in-depth analysis, detailed reporting, and investigations involving complex file systems. AccessData FTK is the fastest and most efficient tool for processing large datasets and handling cases where speed is a priority. Whereas, Cellebrite is the top choice for mobile device forensics, offering unparalleled speed and ease of use in extracting data from smartphones and tablets.

For anyone, especially the NPF, to optimize its digital forensic investigations, it is essential to match the tool with the type of evidence and investigative requirements. By leveraging the strengths of each tool, digital forensic experts/professionals can improve the efficiency and accuracy of their cybercrime investigations.

5.5 Recommendations

Based on the findings of this study, the following recommendations are made:

(a) **Tool Selection Based on Investigation Type:** The NPF should adopt a hybrid approach to digital forensics, utilizing EnCase for complex investigations requiring deep data recovery, FTK for cases requiring rapid data analysis, and Cellebrite for mobile device forensics. This approach will ensure that the right tool is applied to each case based on its specific needs.

(b) **Training and Capacity Building:** Officers should receive specialized training on each tool to maximize their potential. Given the complexity of EnCase, more extensive training is needed to ensure that officers can use the tool effectively. Continuous training on FTK and Cellebrite is also recommended to keep up with updates and new features, especially as these tools evolve.

(c) **Invest in Mobile Forensics:** Given the increasing importance of mobile devices in criminal investigations, the NPF should invest further in Cellebrite and ensure that officers are well-versed in mobile device forensics. This will allow the NPF to stay ahead of trends in cybercrime that increasingly involve mobile technologies.

(d) **Improve Interoperability:** The NPF should explore ways to enhance the interoperability of its digital forensic tools, ensuring seamless integration between EnCase, FTK, and Cellebrite. This will streamline investigations that require data from multiple sources and help maintain data integrity.

(e) Resource Allocation: The NPF should allocate sufficient resources to ensure that the digital forensic tools are regularly updated and maintained. This includes investing in both hardware and software infrastructure to support the continued use of EnCase, FTK, and Cellebrite.

5.6 Limitations of the Study

While this study provides valuable insights into the use of digital forensic tools in the NPF, certain limitations should be noted:

1. **Sample Size**: The primary data were collected from only 20 NPF officers, which may not represent the entire population of forensic tool users in the NPF.

2. **Geographic Scope**: The study is limited to the NPF's operations within Nigeria and does not explore the use of these tools in international contexts.

3. **Tool-Specific Focus**: The study focuses exclusively on EnCase, FTK, and Cellebrite, without considering other digital forensic tools that may also be used by law enforcement agencies.

5.7 Suggestions for Future Research

Future research should address the following areas:

1. Expand the Sample Size: Increasing the number of respondents from different regions and units within the NPF will provide a more comprehensive understanding of how these tools are used across the organization.

2. Comparative Analysis with Other Tools: Future studies could expand the analysis to include other digital forensic tools beyond EnCase, FTK, and Cellebrite, providing a broader perspective on the forensic tools landscape.

3. Focus on Emerging Technologies: With the rise of cloud computing and IoT devices, further research is needed to evaluate how well these tools handle emerging technologies and new forms of digital evidence.

This study has shown that EnCase, AccessData FTK, and Cellebrite each offer distinct advantages in the realm of digital forensics. By understanding the specific strengths of each tool and tailoring their use to the requirements of different investigations, the NPF can enhance its digital forensic capabilities. The recommendations provided in this chapter offer practical steps for improving tool usage, training, and resource allocation within the NPF, ultimately contributing to more efficient and effective responses to cybercrime.

DEDICATION

I would like to dedicate this thesis first to my Maker, for shining His light through another journey. To my spectacular supervisor, advisor and mentor, Dr. Tunde Adegbola. I love the way you father me. Also, to my parents, Prof and Mrs. M.O. Adewumi, their prayers, unwavering support and encouragement have been my constant source of strength throughout. Thank you all greatly, may God bless you.

ACKNOWLEDGEMENTS

My acknowledgement is first to God: the reason for my existence. All praise, honour, adoration and thanksgiving unto Him for He authored and finished this work. I thank Him for grace and the gift of all the wonderful people who shared the burden of this work with me.

I am highly indebted to my Supervisor Dr. Tunde Adegbola a great teacher and mentor for his invaluable understanding, guidance, continuous support, resources and encouragement which saw me through this journey. I am also very grateful to his entire family many of whom I never met physically. They all provided a very friendly atmosphere and a home away from home without which my dream of completing this project could not have been realized. I can probably write a whole book on the millions of ways my Supervisor inspired me, made my life easier and helped me to improve. He shaped me as a researcher and made this journey the best ever of its kind.

I am grateful to Africa Centre of Excellence on Technology Enhanced Learning (ACETEL) for all the assistance and necessary resources provided that brought this out of me. I am particularly thankful to Prof. Grace E. Jokthan, the Centre Director, Dr. Johnson Opateye the Deputy Centre Director for all the wonderful assistance I received from you and the Centre. I am particularly thankful to Prof. Vivan Nwaocha the former Programme Coordinator who so much believes in me and ensures she does her best to support me, I am also very much grateful to Dr. Adeyinka O. Abiodun the current Project Coordinator for all you did to make my dream come true. I cannot but thank the Research Team Lead Dr Juliet Iniegbedion, the Administrative Team Lead, Mr. Udochkwu C. Nwankwo for your inputs which resulted into this success. I remain grateful to all the teaching and non-teaching staff of the Centre too numerous for me to mention on this page.

I would like to express my sincere gratitude to my working place, Robotics and Tech Africa for providing me with the opportunity and support to combine my work with my study. It was a little challenging but it was worth all of it.

I remain indebted to my father and mother, Prof and Mrs. M.O. Adewumi of the University of Ilorin. Indeed, you are the best of parents. May the Lord spare your lives to eat the fruits of your labour. Thanks to my siblings, Emmanuel and Josiah for being my constant motivators. Mr. and Dr. (Mrs.) T.J Olanrewaju presently in the U.S., I cannot thank you enough for what you mean to me and to this project. Col. (Dr.) and Mrs. E.A Oyebanji - you are the angel God sent to Lagos when I needed one most. To Dr and Dr (Mrs.) O. Popoola, Mr. and Dr. (Mrs.)

Omole, Dr.(Engr.) and Mrs. Muyiwa Olanrenwaju, thanks for all your motivation, and support. I cannot forget all so easily. To Engr. and Mrs. Segun Oyebanji, I remain grateful. Pastor and Mrs. Adeyemi, you came into my life when I needed a place of abode in Lagos and there seemed to be none. You took me and adopted me as your own daughter, you made an indelible mark on my life. You cannot be forgotten so easily. I thank you from the depth of my heart.

To the Apostolic Faith family in Ebute Meta, I thank you all for keeping the home front in the course of my shuttling between Lagos and Ibadan. Many thanks for your many prayers. To my friends and colleagues, Mercy Dunmoye, Eunice Odibe, Oyedun Samuel, Boluwatife Ajayi, Olanrenwaju Pelumi, Charles Oni, Sekoni Faith, Joshua Ogedengbe, Ayotunde Fagbenro, Thompson Lucky, Ajiboye Mayowa, Lyada Emmanuel, and Gbigbadua Hammed, I sincerely cherish you for your unwavering support and encouragement throughout my academic progress.

Special shout out to all my Ibadan family Dr. Damola Adeshina, Miss Deborah Ojo, Mr. Pamilerin Idowu, Ayanfe and a lot more for all the unreserved love, support, helpful discussions, kindness, fun, laughter and delicious foods.

Big thanks to my uncle for the chats and a ton of advice to keep me sane until the end of the masters.

ABSTRACT

The increasing influence of social media on public attitudes has attracted some negative online behavours such as trolling. Trolling is the act of deliberately posting offensive, inflammatory or provocative messages that are usually erroneous to manipulate public opinion through the delivery of multiple posts by a few authors (Wikipedia, 2023). These few authors masquerade as very many authors through the use of several pseudonyms on online platforms. They thereby give an erroneous idea on the public state of affairs by giving the impression that most of the population is inclined towards their erroneous idea. Trolling is classified as a cybercrime.

One of the major incentives for trolling is the default anonymity on online platforms. This study offers an exploratory method for detecting common authorship among a small pool of authors masquerading as very many authors. N-grams probabilities of words in documents produced by these authors are used to build language models. Based on supervised learning, these language models classified documents according to the labelled authors. However, the use of the models so built, without implementing the activation function produces a measure of proximity between the documents based on their true authorship. Such measures of proximity may suggest common authorship of sets of these documents. Hereby, leading to a suggestion of common authorship of each set.

A hundred documents from labelled authors were scraped from Quora platform and subjected to supervised learning for classification based on labelled authors. Documents with known common authors were randomly attributed to various pseudonyms and training. Training for classification based on these arbitrary pseudonyms was undertaken with the activation function and document proximity without the activation function was derived from each document. The documents were then clustered according to the various their various authors. This exploratory study used perceptron, a basic approach because of the limited availability of sufficiently fast hardware but it was still able to show that common authorship attribution is possible.

In this study, the optimal learning rate for the two n-grams employed was found to be 0.1. This resulted in only one misclassified document out of 40 test documents when utilizing the bigram feature. The study confirmed the expected impact of the learning rate on the model's accuracy, aligning with theoretical predictions. Notably, support vector machines consistently generate classification models with optimal accuracy. Therefore, future studies should

consider adopting support vector machines and neural networks instead of perceptron models to enhance classification performance.

INTRODUCTION

1.1 Background to the Study

The internet, cloud and IoT devices (cyberspace) is a virtual space that would be hard to separate from humans, this is owing to its enormous benefits in all sectors of our universe. ICT has never stopped being an emerging development, its growth is quite rapid and steady. However, cybercrime has been a major setback to this development, putting our major success claim at a serious security risk (Babayo, 2021). Conventional crimes like raping, stealing, cultism etc., are easier to detect and prosecute by law enforcement agents because their culprits are physical. This is not the case with cybercrime, most of its activity do not involve physical damage but rather intellectual manipulations, which makes tracking them down somewhat difficult (Moses, 2015). One salient characteristic of Cyberspace that incentivizes the compromise of Cybersecurity is '**anonymity**'. Hiding behind the virtuality offered by digital electronics and the ease with which true identity may be masked, unscrupulous individuals are encouraged to engage in online antisocial behaviour, believing that arbitrary identification makes them virtually nameless and so they cannot be identified. Meanwhile, identity is of prime importance in virtual interactions on our social media and even Distance Learning as we have here in ACETEL.

Cybersecurity attempts so far place a lot of emphasis on building robust tamper-proof systems that are difficult to hack. Valid and effective as this may be, it is also beneficial to address cyber security from a social-psychology standpoint by depriving the potential cyber criminals of anonymity and the negative benefits that accrue therefrom. Taking advantage of developments in Artificial Intelligence (AI), authorship attribution can be employed to identify individuals operating in cyberspace by virtue of their individual styles of writing and other personal idiosyncrasies retrievable through Natural Language Processing (NLP). This offers a supplementary scheme that can be used to discourage deceptive online activities such as trolling, phishing, and cyberbullying, all of which thrive on anonymity and misidentification. These crimes should be discouraged if not eradicated to consolidate cyberspace gains from ICT development.

(Dan, 2014) examined different definitions of Cybersecurity in order to create a more succinct definition. The resulting definition describes Cybersecurity as the arrangement and

management of assets, procedures, and frameworks employed to safeguard cyberspace and systems enabled by cyberspace. Its purpose is to prevent incidents, whether deliberate, accidental, or resulting from natural hazards, that disrupt the rightful ownership of digital properties and ensure that they remain in the correct hands, avoiding any misalignment between legal and actual ownership. Furthermore, this definition highlights that Cybersecurity extends beyond technology alone and encompasses a broad spectrum of elements including resources, processes, and structures. It is also an interdisciplinary field encompassing virtually all fields and is not limited to cryptographers and computer experts. It spans lawyers, sociologists, administrators and educators (Dawson, 2020). Integrating and advancing multidisciplinary knowledge and social awareness can offer better and timely protection of citizens (Eleni, 2018). The comprehensive aspects of Cybersecurity involve the gathering and arrangement of resources, processes, and structures, encompassing various interactions among humans, systems, and the interactions between systems and humans.

The core values which Cybersecurity preserves are the CIA triad (Confidentiality, Integrity and Availability) and the AAA (Authentication, Accountability and Authorization) of digital and information technology. Confidentiality ensures secrecy by ensuring only authorized users and processes can access or modify data (Securityscorecard, 2021). Integrity objective requires maintaining data state without modifications either intentionally or accidentally. The ATM (automated teller machine) and bank software enforce data **integrity** by ensuring a reflection of any transfers or withdrawals made via the machine on the user's account (Fruhlinger, 2020). Availability implies that systems, functions, and data must be available on demand upon agreed parameters based on the SLA service level (Yuhong, 2021). The triple A's model has the first A as authentication, aiming to validate users and this usually is ensured with a password or two-factor authentication. Authorization demarcates a level of access a user has usually tied to the user's privilege. The last A is for accounting its objective implies tracking users' actions and a user taking responsibility for their actions (Nweke, 2017) . Cybersecurity also went a step further by classifying security in cyberspace at different layers (Edyta, 2021). This resulted in three classes;

The technical layer covers the hardware, software and physical security measures. Physical Security is a crucial part of any security plan and it forms the foundation for all security endeavours, without it, other security layers are considered tougher, if not impossible, to initiate. It necessitates robust building infrastructure, effective emergency readiness, dependable power sources, and adequate safeguards against unauthorized entry. Security

professionals concur that access control, surveillance, and security testing are the three crucial elements of a physical security strategy. These components collaborate to enhance the overall security of your premises. (Kisi, 2019) . Antivirus programs, firewalls, IDS/IPS systems etc. are for protecting software. Cyberspace is an evolving and complex system therefore the security provided should also follow this pattern.

The strategic layer implies the legal legislation and standardization for Cybersecurity at individual, national and international levels. This layer regulates the rights and duties the cyberspace users. An essential body in this layer is the National Security Advisor which coordinates the body of all security and enforcement agencies under the act (Udo, 2018). NSA produces cyber threat intelligence, share guidance and provides Cybersecurity assistance to prevent and eradicate foreign cyber threats to National Security Systems (Fort, 2021). A significant example is at the 7th meeting where the review of cyberspace emerging risks and regulations to facilitate the implementation of the National Cybersecurity Policy and Strategy took place.

Social layer: The Social layer defines the manipulation of people through various psychological tactics to gain unauthorized access to information. The greatest asset to this layer is information. It goes from societal interactions down to individual interactions. The social layer is termed the most vulnerable to numerous types of attacks that target human cognition, including social engineering, cyberbullying, hacktivism, trolling, terrorism etc. The social layer is constantly under siege and vulnerable even when technical and strategic layers are patched and properly functioning. It is the most prone to information attacks (David, 2019). Information is anything from which people can derive meaning, regardless of accuracy or fact. Information storage has gone digital. Therefore, information security has a crucial effect on Cybersecurity (Kaja, 2021). Information warfare in this layer involves users manipulating information in a way that alters the target perception of a topic or event. A well- planned sequence of information and psychological maneuvers designed to sway the viewpoints, beliefs, actions, emotions, motivations, rational thinking, and ultimately the conduct of foreign governments, organizations, groups, and individuals in a manner that aligns with the goals of the initiator (Dawson, 2021). (Samantha, 2017) analyzed the detail strategies, techniques and tools used in information warfare in the social layer as:

i. Commenting on social media posts: involves cyber troops engaging the users by commenting on the post shared on social platforms. A diverse mechanism is used here

adopting positive comments to buttress the government's position or ideology. Neutral comments strategy is also used aiming at drawing away attention from the discussed topics. The last techniques and strongest technique are the use of negative statements for dialogue such as harassment, trolling and abuse.

ii. Individual targeting: when a selected group or a sole person is influenced. Carefully chosen activists, bloggers, and journalists are singled out and strategically influenced with targeted messages in order to manipulate the opinions of their followers and shape their beliefs and values.

iii. Government-sponsored accounts, web pages and applications

iv. Fake accounts and computational propaganda

v. Content creation.

Human behavior (factor)

Cybersecurity is falsely perceived as solely technology solutions driven. The technical-driven solutions are its actual foundation but human influence cannot be trivialized. Human behavior is one of the biggest risks associated with network security and understanding human behavior is vital to identifying anomalies and preventing cybercrime (Columbia, 2021). (Aljiebi, 2020) stated the great need to focus on the people who are engaged in cyber operations and not just the systems. The article further stated that human behavior lacks consistency and can be influenced by relationships.

In 1999, Bruce Schneier noted Cybersecurity to be about people, processes and Technology. Cyber attackers the people aspect of Cybersecurity, seek to manipulate the minds of computer system users, rather than the computer system itself, using social engineering (e.g., tracking of computer system users to gain information, such as passwords) and cognitive hacking (e.g., spreading of misinformation) to break into a network or computer system (Ahmed, 2011).

Looking at behavioral economics, sociology and psychology can help us understand how we can better engage people to improve Cybersecurity. Scientists in these fields have tried to study human behavior: how we think, what motivates us to do things and lots more and the lessons from these fields can be adapted to advanced Cybersecurity (Barker, 2019) . Cybersecurity was usually affirmed using technology-centric methods (e.g., firewalls,

antivirus software and Intrusion detection systems) with little or no concern for the user's cognitive processes, understanding and motivation. The human element is caused by errors and intentional violations. Relative to the growing technological advancement in security, the user's behavior keeps causing a breach through carelessness, ignorance, lack of awareness and deliberate actions. Cybersecurity can be further ensured by implementing solutions that are able to minimize human incentives and shape attitudes in cyberspace. This involves a consequence for users' misbehaviour, awareness and training. The problem caused by humans (cyber-users) is associated with psychology. Therefore, psychological methods can be used to improve users' compliance with security. Such psychological methods include using novel polymorphic security warnings, rewarding and penalizing good and bad cyber behaviour, and creating the consequence of actions (Ahmed, 2011).

Anonymity

Anonymity was derived from two Greek words, "an" and "onoma" meaning without and name respectively (Medium, 2018) . Online anonymity means that the real author of a message is not shown i.e., anonymous. It gives us power to control our appearance and personality in the virtual world. Users can create an identity and choose their personality to control other users. Online anonymity allows users to present different forms of themselves in an online environment (Wikipedia). It fuels lack of identifiability by other Internet users and the inability to link information back to the individual's offline identity. Online anonymity creates a bridge that makes it hard for it to be classified as good or bad (Erica, 2017). The users' motivation for anonymous online expression has an opposing variety, called the "**online disinhibition effect**". The online disinhibition effect works in two opposing directions classified as benign and toxic disinhibition (Suler, 2004).

The benign disinhibition effect encourages users to discuss controversial topics like politics, abortion or their struggles without fear of rejection or judgment. They are able to explore new and undiscovered aspects of themselves. Technology is also significant in improving mental health just like medicine (Palme, 2012). "A free-to-be-me-human" is mentally healthy with a renewed sense of identity. A sincere evaluation of a user's posts or messages may also be gotten by shielding them with anonymity. This can also aid legitimate whistleblowers in exposing information or activity deemed illegal or wrong at a place of work or a community.

However, the toxic disinhibition effect is the misuse of this freedom of expression by using rude language, harsh words and even threats. The users engage in visiting immoral sites for pornography, crime and violence.

Possible Consequences of Toxic Disinhibition

Anonymity aids **social engineering** by building trust through human interactions. A user possibly claiming to be a new employee, a repair person, or a researcher or even offering credential gotten from identity theft to support the chosen identity this gives access to obtain or compromise information about the organization or its computer systems (CISA, 2009).

Phishing is another form of attack. It refers to accessing the private information of any individual through illicit means with the aim of using such information for illegal purposes. The most common type is carried out when the culprits sends an E-mail to a user falsely claiming to be an authorized or legitimate enterprise with the aim of tricking the user into surrendering private information that will be used for identity theft (Ikenga, 2015).

Malware spread which usually exploits hardware, software and network layers has advanced its cause to emerging technologies using social media, cloud computing, smartphone technology, and critical infrastructure to avoid detection (Julian, 2014). Cybercriminals keep inventing more sophisticated methods to appear as trustworthy users to trick users in social network sites into "friending" or following them and clicking on their status updates which often leads to malicious software (Julian, 2014). (Weimin, 2009) demonstrated that a high number of malwares were spread from clicking content on trending topics via Twitter. The victims of malware attacks vary from end-users, servers and network devices like routers, switches, etc. to processing critical infrastructure (Julian, 2014) like the SCADA.

Cyberbullying is the aspect toxic disinhibition effect most associated with anonymity (Luke, 2011). It comes in different forms which can include harassment (insults or threats), masquerading, cyberstalking, trolling etc. These activities can be performed via e-mail, instant messaging, text messages, social networking sites such as Facebook or Twitter, and other websites (Erin, 2014).

i. Online harassment

Repeatedly sending offensive messages, revealing a secret that would rather be kept private from the public, or showing unrequited affection is known as online harassment. A good percentage who are being harassed online usually don't know who was harassed, because the

aggressor was either a stranger or the real identity of the person(s) responsible wasn't known (John, 2017). This can happen if the person created a fake account, used an alias, or took other steps to hide their identity. Ultimately, it degrades someone's self-esteem and makes kids feel lesser spreading rumours, creating web pages that depict them negatively and sending threatening emails.

ii. Cyber stalking

Cyber stalking is fuelled by rage, power, control, and anger that can be precipitated by a victim's actions or inactions. (Pittaro, 2007) suggests that there will be an increase in cyber stalking incidents partly, because the Internet provides a safe haven in which an offender can hide and conceal his true identity behind a veil of anonymity. The anonymity of the Internet also aids the perpetrator a privilege to reach virtually anyone with Internet access, at any time, with little or no fear of being identified and not to talk of fear of being prosecuted under the current legal system in many jurisdictions. The abundance of personal information online, including celebrity web pages is another incentive for cyberstalking. It has erased the lines between unapproachable and accessible, increasing the occurrence of cyberstalking, including celebrity victims and media icons (Michael, 2012).

iii. Trolling

A less understood form of Cyberbullying is trolling. The disruptive aspect of trolling distinguishes this behaviour from other forms of online antisocial behaviour, like cyberbullying (March, 2017) . Originally, the word trolling is a method of fishing that employs dragging a hooked lure or bait through the water from a moving boat. It is arguably the most effective way to catch fish (Nikolic, 2021). This term was adapted as a slang on the internet referring to deliberately posting antagonistic or erroneous messages or comments to provoke a reaction. It's a bait that lures the public's attention or manipulates their opinions. Cyber trolling is largely encouraged by the anonymous nature of the internet which made Donath characterized trolling as "a game about identity deception" (Susan, 2002). Anonymity makes it easier to operate with operatives creating dozens or hundreds of accounts to stimulate users' attention (Michele, 2020). Trolling comes in different forms ranging from a type of game to communicative violence, a technique adopted by anonymous political activists and as a pro-governmental propaganda strategy. Trolling goes beyond just teasing, it goes a step further to harassment. A method that has been adopted to curb this crime is a

refusal to enter into a dialogue with the troller, as expressed in the popular term “don’t feed the trolls” (Hardaker, 2013)

One of the events that have recently attracted wide attention is the foreign interference in 2016 where the U.S. intelligence community indicated 13 Russian nationals in 2018 associated with the Internet Research Agency (IRA) based in St. Petersburg, for interfering with the 2016 U.S. Presidential election with the goal of harming the campaign of Hillary Clinton while boosting the candidacy of Donald Trump. This Internet Research Agency (IRA) was described as a troll farm that created thousands of social media accounts, pages and groups using false American persona. Fabricated articles and false information designed to attract American audiences and sow discord were spread through this medium. The consequences of these actions were terrible, it almost led to the impeachment of Donald Trump, affected the Russian economy and almost breached the relationship between the world’s two superpowers (U.S and Russia). Also, these actions exemplify the trends in modern online communication, propagating things like fake news, post-truth and alternative facts (Monakhov, 2020). Despite the perseverance of this crime, it is under-researched when compared to other cybercrimes (Hardaker, 2013) , (Monakhov, 2020) . Trollers are fond of creating many accounts in order to attract attention and solidify their false information. Previous work has mostly looked at campaigns run by bots (Savvas, 2019). Therefore, this research intends to address the issue of identifying trolls and classifying them by their source.

Technology-centric Solutions (Cybersecurity)

- Antivirus, Firewall, Intrusion Detection System

Antivirus software immunizes systems against malicious software or codes that threaten the operating system or data. It proactively detects, neutralizes, and disposes malware (Vigderman, 2021) . Antivirus Signature-based and heuristics are used in identifying and removing suspected files or programs. It works by identifying a threat, this prompts the user or system into action. This could be resolved by not downloading the suspicious file, deleting a suspected mail or not proceeding to a webpage (Wikipedia, 2011). A firewall monitors incoming and outgoing network data, it either allows or denies the data depending on the configured rules. It is usually the first line in the defense perimeter (Mixon, 2021).

Majorly, antivirus, firewall and Intrusion detection or prevention systems are installed as perimeter defense models. They intercept incoming traffic to examine they are malware free. However, the synergy of this defense perimeter has been found not so effective owing to the

modern malware. This new malware seems to always find a loophole to bypass the combined defense (Julian, 2014).

- IP Address tracking

Robert said IP Address is a ‘Smoking gun’ that inexorably links offensive posting to its address. It connects the computer to a physical address (MAC address). Each computer is assigned a unique Internet Protocol (IP) address when connected to the internet. Therefore, it is possible to link all communication and online activity back to the real identity by tracing the data to the IP address, the IP address of the computer, and then the computer to the individual (Stephanie, 2015). The IP address is logged by the Internet Service Provider and the host website. The information held by the ISP is actually more critical, and it requires a court order to access this. While an IP address stored by a website might be able to lead a forensic expert to the ISP that enabled the Internet connection, the IP address held by an ISP can actually lead the expert to an Internet troll's front door (Heussneur, 2010). However, IP address is not enough to get a hacker because technologies like Kali Linux, TOR (The Onion Routing) and VPN (Virtual Private Network) aid a user in encrypting all outgoing or incoming traffic masking the actual IP address. The Onion Router (TOR) uses onion routing to provide each user with a masked IP address instead of the one assigned to the user’s computer (Stephanie, 2015).

Cyber Security with Artificial Intelligence (Natural Language Processing)

Online anonymity is, in its essence, a multifaceted phenomenon that can best be understood from an interdisciplinary approach (Lina, 2021). There are various means of communication on social media platforms. One of the most popular is via text posts. Natural Language Processing requires adopting traditional method to these texts and developing a suitable and safer information exchange platform. Natural Language Processing (NLP) is an area of artificial Intelligence which specializes in interpreting human communication through computational machine learning models. Human words are being analyzed, which allows algorithms to get the meaning of full sentences expressed by people. The NLP model can understand the expressiveness of a phrase, interpret the desires or emotions of a person from the use of certain words, or even establish similarities of intentions between sentences (Susan, 2002). Detecting groups of related topics, rumors, emotion and incentives is important for social network applications (Atefeh, 2018). The automatic pre-programmed processing of

social media platform data needs appropriate research for applications such as categorization, clustering etc. This will help to understand the sources of these information, perform sentiment analysis on this with common interest and get alerted against any potential threats for defense. This method has been tried by manually monitoring but is less effective when compared to the automated media with its numerous texts (Atefeh, 2018). NLP have proven their potential in the support of cybersecurity labours and particularly in the detection of cybercrimes. Researches have shown how inventive NLP methods can merge appropriate Linguistic information in various sectors such as social media, healthcare, security and defense (Atefeh, 2018).

The adoption Natural Language Processing for authorship attribution solutions by law enforcement agencys would strengthen a national cyber defence strategy reducing considerably the time of attention to cybersecurity incidents and providing Law Enforcement Agencies (LEAs) with the capacity to detect and prevent Hard Security Mechanism (HSM) (Monakhov, 2020).

Trolling is a human created crime therefore the use of natural features of human like language should be considered to discourage this crime by authorship attribution. It is therefore pertinent to provide solutions that can assist Cybercrime forensics investigators and detect cyber criminals. This would enable them to track and prosecute the right perpetrators.

Authorship Attribution

Authorship is defined by the oxford dictionary as the state or fact of being the writer of a book, article, document, comments or creator of a work. Attribution is seen as ascribing a work to a particular person or thing (Wikipedia). Authorship attribution, therefore, is unveiling the originator of a piece which could be a book, article or anything that has features that can help to point to its author.

Authorship attribution captures significant features from author's writing style for the identification, this is called stylometry and the process is called feature extraction. The linguistic features that can be captured include; lexical, syntactic, semantic, application-specific and character N-gram (Fatma, 2020). Stylometry is the behavioural feature that an author exhibits throughout his writing. Therefore, stylometry has the potential of identifying the authors of texts.

i. lexical features represent the vocabulary richness of a language. This considers each word that makes up a sentence. It is a common misconception to believe words of different languages typifies the same inventory of things, processes and qualities. Translation would have been somewhat easier if this was true but people narrate similar experiences or stories in various languages. A person's view of the universe and the people around is closely linked with his first language. Children in fact, develop their understanding alongside with their first language (Crystal, 2021).

ii. Syntactic feature relates to the positioning of words and phrases that makes up the sentences. Unlike lexical, syntactic concentrates on sentences, the features here are derived from the arrangement of sentences. Positional features like placing an important clause at the beginning vs. at the end of a sentence. The use of active voice, a more direct and energetic or passive voice (Gaurav, 2019).

iii. semantic refers to the meaning of the text in language levels. Semantic entails the meaning of the whole text, after combining the word, and sentences. The core meaning of all vocabulary and sentence or phrases arrangement. It entails the meaningful functions of phonological features, such as intonation, and of grammatical structures. Semantic features are identified by analyzing the larger meaning of the text (phrase, sentence, or paragraph), unlike lexical or syntactic features that considers the meaning of the comprising words or the positions of the sentence (Gaurav, 2019).

IV. Character level includes character n-grams, frequent suffixes, letter frequencies, punctuation usage etc. Character N-gram is a set of repetitive words from a text. It is a type of probabilistic model language model for prediction of the next word, also known as shingles (Yunita, 2018).

v. Application-specific features are considered when texts from webpages like emails, considering the layout (signature, indentation) and structure of the codes. Some applications like metadata record the event logs with date which will help in the authorship attribution (Fredick, 2019).

Authorship attribution can be defined to address three different problems. The first is, identifying an unknown author from a given set of authors. This is often classified as 'closed class authorship attribution' it determines the author of a particular piece of text where the set of authors is known. The second problem is author verification, it answers whether a sample

of text document was written by a suspect (one person) with the help of some provided written documents. The third class of these problems is often referred to as profiling.

Closed-class and Open-Class Attribution

Closed class and Open -class are gotten from English words used for categorizing part of speech used for pronoun and conjunctions, a part of speech that does not acquire new members frequently if it does at all- closed set and the nouns, verbs and adjective that takes in new members regularly (Wikipedia). Closed and Open class set attribution is similar to this. A closed set attribution problem is usually provided a set of authors and the samples of text documents. The given set of authors must include the author of the questioned text or document. For the Open class set, the information provided here most times is to train the model, the true author is not necessarily in the set of provided author set. This a more realistic scenario although it is quite a more difficult problem than that of the closed-class version.

Many researchers assumed that everyone has a characteristic pattern of language use that can be identified in their writings, this can be called "authorial fingerprint". A set of computable traits that can uniquely identify a particular author. These traits exist because language learning is an individual action in which everyone encounters different learning experiences that makes a micro difference to their language (Patrick, 2008). Also, even if they use the same words the word combinations and patterns are usually different.

Authorship attribution (Verification)

This project is set to address the type two problem of authorship attribution, which is a group of text that is identified as singly authored or not using Natural language Processing tools to obtain the linguistic features that identify a user and differentiate him from the rest. Verification focuses on learning the differences between a pair of texts rather than the characteristic of each author. With an open-class set, this problem is said to be more difficult because an author may consciously or unconsciously vary his/her writing style from text to text. (Yunita, 2018). Authorship verification problem uses two methods: intrinsic and extrinsic verification methods. The intrinsic method depends on the referenced authors and the provided text for verification (to determine whether they are written by a similar author or not) while the extrinsic method uses additional document by other authors to verify the writer. It collects additional external documents written by other authors for author verification (Oren, 2016). Authorship verification has been applied in for several interdisciplinary solutions, to reveal the authorship of disputed or historical documents. This addresses

plagiarism. In Cyber security, it has been used for filtering phishing mails, detecting fake accounts and in user authentication. It is also used to identify fake news from different spreaders but same author.

1.2 Statement of problem

Anonymity promotes cybercrime and de-anonymizing users of the internet is a disincentive to cybercrime. This project uses Natural Language Processing for common authorship attribution to deanonymize internet users particularly on social media. Common authorship attribution is the process of attributing more than one documents purportedly written by more than one author to a single author. It differs in a significant way from mere authorship attribution in the sense that while authorship attribution attributes a document to a particular author, common authorship attribution attributes a set of documents to a particular author.

The problem of common authorship arises as an undesirable cyber behavior when one person authors several documents with several pseudonyms in order to give the impression that the view represented in these documents is the view of many different authors. In such situations common authorship attribution may not necessarily unmask the author but suggests and sometimes confirm that only one person holds this view purportedly held by many members of a given population. The project therefore, uses the perceptron to classify or cluster sets of documents around a single author based on the author's writing style and other idiosyncrasies.

1.3 Aim of Study

This project seeks to explore the viability of attributing authorship of more than one document to a single person. By investigating the statistical similarities in these documents. This is based on the established fact that the elimination of anonymity discourages cybercrimes such as trolling.

1.4 Specific Objectives

The objectives of the project are:

1. To develop a model that can measure the proximity between two documents based on authorship attributes.
2. Determine the extent to which accuracy in Authorship Attribution can be improved by the manipulation of functions words in the corpora used in the training of the Authorship Attribution model

3. To determine the optimal n-gram amongst unigram, bigrams, trigrams and higher-ordered n-grams for increased accuracy in common authorship attribution.

1.5 Scope of the Study

As an exploratory study, the scope of this study is limited to the use of the perceptron to classify online platform posts according to their authorship based of the use of n-grams.

1.6 Significance of the Study

With the proliferation of social media and its use as a tool for perception management, it is important to ensure the validity of the information shared. Trolling, cyberbullying and other such social media vices need to be discouraged, in order to sustain the integrity of information shared on social media. This study offers a means of discouraging the use of trolling, cyberbullying and such methods to present false popularity of unpopular opinions.

1.7 Definition of terms

Authorship Attribution: a process of determining who the author of a document is Common Authorship attribution

Anonymity: anonymity in this context refers to a situation where the writer of an online posting is unidentified or masked as someone else (Identity theft).

BOW: Bag of words is a vector representation of written text, which can be characterized by the frequency of words in a text or probabilities of the frequencies (Jan, 2017).

Natural Language Processing: Natural language processing is a branch of artificial intelligence that studies, processes and retrieves information from human natural languages like text data (Oracle, 2023)

Trolling: Trolling is the act of deliberately posting offensive, inflammatory or provocative messages that are usually erroneous to manipulate public opinion through the delivery of multiple posts by a few authors (Wikipedia, 2023)

N-grams: refer to a consecutive sequence of n-words that appear in a text. Common examples include bigrams, trigrams, 4-grams etc. (Jan, 2017).

Stylometric: It involves implementing statistical and computational techniques to identify patterns and distinctive features in written text to determine authorship attribution.

SVM: Support Vector Machine is a type of machine learning that aims to discover a linear hyperplane that effectively separates instances belonging to different classes. Based on the

location of new observations relative to this decision boundary, they are assigned to one of the classes (Jan, 2017).

Features: they are measurable qualities of a document that can be used to characterize an author's writing style, distinguishing the different fingerprints of an author (Brian, 2019)

1.8 Organization of thesis

The remainder of this thesis is structured as follows:

Chapter 2 of the thesis, which follows this section, is a literature review that examines relevant subjects. These include; cyberbullying, authorship attribution, feature selection and extraction, as well as classification models in order to identify relevant knowledge gaps in the literature. This leads to Chapter 3 which examines the methodology, by which the knowledge gap identified in Chapter 2 can be validly and consistently addressed. The results obtained in Chapter 3 are reported and analyzed in Chapter 4 whilst in Chapter 5 these results are discussed in order to highlight the conclusions and relevant recommendations that arise from the result.

CHAPTER 2

2.1 Preamble

This chapter provides a general overview of the authorship attribution procedures with stylometric features. The highlights from previous approaches are identified through literature review of general and related authorship attribution studies. Additionally, the knowledge gaps were identified

2.2 Theoretical Framework

The theoretical framework in the de-anonymization of authorship is based on language modelling. Probably the most popular method of language modelling is the use of n-grams as a probabilistic feature of the text. N-grams have the capability of characterizing the language of a document, the subject of a document, the purpose of the document and of prime relevance to this study the authorship of the document. The literature is replete with studies in which n-grams were used to model various aspects of written text. This study uses the perceptron algorithm to classify written text according to their authorship based on n-gram probabilities of words in the text. One advantage of using the n-gram feature is that N-grams are independent of the language under consideration (Ashwin, 2012).

Common Authorship Attribution

The similarity-based approach is based on the idea that if two documents (or collections of documents) from the same author are similar, they will be closer together in a spatial representation. By measuring the distance between two authors, we can determine whether they are likely the same person. Various studies have adopted this approach by representing authors using vectors and identified n-grams as the most chosen feature for this (Nicole, 2019).

N-grams

N-grams play a crucial role in various language modelling tasks within natural language processing (NLP). They refer to contiguous sequences of n items, which can be words or characters depending on the application.

In Natural Language Processing, n-grams are widely used for language modelling, text generation, and information retrieval. Analyzing the frequency and patterns of n-grams in a given text or corpus provides valuable insights into the language and its structure.

The most common types of n-grams are unigrams, bigrams, and trigrams. Unigrams represent individual words, while bigrams consist of pairs of adjacent words, and trigrams involve sequences of three words.

N-grams are valuable because they capture both local and global context within a text. For instance, a bigram can reveal the relationship between two neighbouring words, shedding light on common collocations. Trigrams take this concept further, enabling a more comprehensive understanding of language structure and dependencies.

Statistical language models often use n-grams as fundamental building blocks to estimate the probability of a word or sequence of words given the context.

Nevertheless, n-grams have limitations. As the value of n increases, the number of unique n-grams grows exponentially, leading to the sparse data problem. Higher-order n-grams may suffer from insufficient training data, resulting in unreliable or inaccurate predictions. By analyzing n-gram patterns, we can gain a deeper understanding of text, improve language models, and enhance the performance of NLP systems.

2.3 Review of relevant literature

Features are measurable qualities of a document that can be used to characterize an author's writing style, distinguishing the different fingerprints of an author (Brian, 2019). Diverse features can be selected to be extracted for attribution tasks, including Lexical, syntactic, semantic, character n-gram, content n-gram etc. Acquiring the features implies the study of the linguistic and literary (hermeneutic) aspects of a text, seeing this as an approach that backs up modern science. Feature selection is used to lower the complication of a text. The study of the author's idiolect (frequency and distributions of text in language unit) and the author's individual writing.

The lexical features

Lexing is a process of transforming the sequence of characters in a text into a sequence of tokens (Vaikunta, 2020). This is also known as tokenization. A general description is that lexicon is a person's mental dictionary and the development of this dictionary begins with word learning which started as far back as when a child learns her first word. Lexical features are used to discover an individual's most preferred words from the frequency of individual alphabets, special characters, the total number of upper-case letters used at the beginning of the sentence, the average number of characters per sentence, punctuation marks

count etc. (Albert, 2018). Language-based model agrees each word can depend upon any other word within the same sentence. An author most definitely does not choose the next word solely based on their last word, but instead based on all the other words in the sentence. It is a word dependency structure. However, there are a number of limitations to these features the result accuracy varies with the text' length. A longer text will reveal a better word frequency than a short message. To explore further reveals that texts relating to a particular topic will be filled with frequent terminologies of that topic which are usually not often changed with the author's favorite or preferred synonyms. Lexical features are also dependent on the number of training samples available. A large training data set is required to get the model ready for the test data.

Monoconic is a Software employed by (Aliakbar, 2014) to create word lists of large data in frequency order. This study reported an observation that grammatical words such as pronouns, articles, conjunctions, relative pronouns, etc. were the most frequent words on their list followed by technical words (words relating to the subject of the text). The frequency of these two categories cannot be avoided. Therefore, the paper, suggested that the quality of lexical features should be improved before they are used for classification. (Aliakbar, 2014).

(Maengsik,2014) also explored lexical features alongside character n-gram and syntactic features, in classifying authors using a fixed hybrid N-gram window for sentence-level sentiment analysis and presented a support vector machine approach with lexical and syntactic features derived from different textual levels in the document. The research noted that syntactic features improved the lexical features this was observed from an improvement in the accuracy of their classifier.

Syntactic Features

The syntactic feature is the most fundamental in the hierarchy of features that can be extracted, it operates by accounting for the basics i.e., the phrase structure and its dependent relationships with other words in a text or sentence. Each sentence is represented as part of a speech tag (POS). Syntax is the study of the method of combining words to form phrases and sentences. (Radford, 1997) termed syntactic features to study the level of language that lies between words and the meaning of the utterance. It starts from the use of simple phrases, a group of words denoting a single idea but not containing the subject or predicate, and expands to simple or compound sentences (Umaru, 2013).

(Haiyan, 2021) transformed each word into a phrase dependency tree structure before inputting it into their **M**ulti-**C**hannel **S**elf-**A**ttention (MCSA) model. The transformation enabled each sentence to be represented by words, POS, phrase structure and dependency relationships. Word representation is influenced by its position in a text. This relationship is seen in a tree hierarchy as the longest path between the root and one of the leaves with the width as the maximum number of siblings that there are at some level of the tree (Juan, 2016).

Syntactic features have been however limited to a linear order of the sentences, regardless of their semantic complexities. The syntax of a text alone cannot construe meaning, especially because of the limitation of word order (Girard-Gillet, 2012). Researchers, therefore, noted the absence of a direct link between a syntactic function and a semantic interpretation. The complex interactions between related words in a sentence and the position they appear in that language enable us to communicate our thoughts.

Semantic Features

Semantic features identify the meaning of a text by analyzing the grammatical structure between individual words. Symbols, signs and the collocations of words that appear together are also considered. It interprets the context of natural language to detect sarcasm, and emotions and to extract vital information from unstructured data. It helps to achieve up to human-level accuracy. Semantic features can be explored to classify text into a topic-related classification based on its content, a sentiment classification i.e., the type of emotion behind the text either positive, negative or neutral, an instance is a sentimental online forum posting to get to know how the employees feel about their company and being able to identify disgruntled staffs almost immediately and also an intent analysis which is used to determine interest. Semantic features is a powerful machine learning tool that delivers valuable insights to drive better decision-making and improve the model experience. It is a commonly used feature for function words, phrases, or sentences that are not so easy to extract. Individuals' ethnic, psychological, moral etc. nature is revealed in their writing culture.

(Aurek, 2021) explored the semantic feature using natural language support for classification tasks and recommended that semantic features could go further than the PoS syntactic feature with its distinguishing power by implementing semantic frames into machine learning classifiers and the classifier was seen to have a higher accuracy when Syntactic features were replaced with the semantic features. This research went further by combining the two features to check if the combination of the two features would improve its accuracy but an unexpected

lower accuracy was the outcome, pointing to the effectiveness of semantic features for practical settings.

(Haiyan, 2021) considered four different features: style, content, syntactic and semantic features, using Multi-Channel Self-Attention Network (MCSAN) a variant network model to extract the different features. The additional features used here help to distinguish different authors. The method also introduced phrase structures and brought a closer relationship between the words, helping to transform phrases with their corresponding dependent word. The variant feature mechanism used here was to separately extract the different features one after the other, then after training the model, it also simultaneously extracts the four features to be used. This made their paper come up with a comparison between the style marker that relies on a bag of words (semantic feature) Vs that of the sequential rules. Sequential rules are data mining rule that finds the interesting frequent characters and patterns sequence of a database. Support Vector classifier was used with the sequential features and a good attribution performance was achieved until a certain limit revealed that adding more rules improved the attribution model. Conversely, the semantic approach of function words with the bag of words model exceeded that of the sequential rule, achieving a near-perfect result.

Conclusively, features extraction methods definitely perform better than one another but the best bet is using the features that fully represent the text to be attributed and also the optimal features that can be used to infer the sentiment class of the text.

Classification Models Review

The common suggested classifiers for authorship attribution will be reviewed to get the best model that suits the aim of this project. Accuracy, precision, recall and F score are often used in knowing the performance of the classifiers. A model that could not get the exact author shows low accuracy. To know the best-fit classifier model for Authorship Attribution, researchers have compared different machine learning models such as; decision tree, random forest, Naïve Bayes, SVM and Neural network (deep learning models) (Naim, 2020).

Machine learning Classifiers/Models

- Naïve Bayes

The first computer-based approach to the authorship of the Federalist papers used this classifier which was called Bayesian before Naïve Bayes. Naïve Bayes is a probabilistic classifier, which predicts the likelihood of occurrence of an object. Naïve Bayes is made up

of two key names, ‘Naive’ and ‘Bayes’. Naïve literarily means unaffected or unexposed, which is similar to that of Naïve Bayes which assumes that the occurrence of certain features is unaffected or not influenced by some other features (JavaTpoint, 2021). Bayes named after Thomas Bayes is based on a principle called Bayes Theorem which states that the probability of an event is based on the previous knowledge of an event related to the current event (Wikipedia, 2022). It is a conditional probability.

- Decision tree classification algorithm

A tree-structured, starting from the root and expanding with branches supervised learning technique, with its internal nodes representing the features of a dataset and its branches the decision rules. Each leaf node then represents the outcome. Usually, a decision tree has two nodes, the decision nodes which contain other branches and are used for making decisions and the leaf nodes which serve as the output of the decisions. Using the decision tree model has been found quite easy compared to other types of models in terms of Interpreting the result of the decision tree classifier but this model is challenged by not producing good results with noisy data. Noisy data is data with a large amount with additional meaningless information in it. Also, to reduce the error rate decision tree often needs a pruning technique. Decision trees are presented like a flow chart, with a tree structure wherein instances are classified according to their features (Naim, 2020).

- Random Forest Classifier

A random forest classifier is also a tree-based approach with supervised learning (with a known target variable). This is derived from the decision tree classifier by using a random selection of attributes at each node. Each classifier is an ensemble (a decision tree) of which the collection of the classifiers is a forest. This model is more accurate and needs less computational power to process than the Decision tree. Its performance is quite fast and vast too. However, it is attributed to a complication in the interpretation of results. The accuracy of a random forest depends on the strength of the individual classifiers and a measure of the dependence between them (Leo, 2001).

- Support Vector Machine

A machine learning algorithm that specializes in regression and classification challenges. However, it is popularly used for classification problems. It finds the best hyperplanes to separate different classes. It is a linear classification technique where different classes are generated by separating the training data into two with Marginal Hyperplane or line. A Marginal hyperplane is a line that best separates the tags. To ensure the right hyperplane is selected from a number of possible hyperplanes from the graphical representation, the distances between the nearest data point and the hyperplane is reviewed. This distance is called '**Margin**' The maximum margin then has the best hyperplane (Sunil, 2017) . SVM overlooks outliers (a point that deviates significantly from the rest objects). SVM has two main benefits, a higher speed and better performance with a limited number of samples. This makes the algorithm very suitable for text classification problems, where many tagged samples can be derived. Professionalism is not needed to build an SVM model, it reduces data size using stratified sampling, which makes it an easy procedure and, in most cases, data preparation is not necessary.

(Dewi, 2010) according to some research, a machine learning model performs better when the model finds 2500 words per text but for short text (e.g., 100 to 200 words) SVM performs better compared to other models such as Random Forest. Furthermore, model overfitting reduces the performance of classification. Compared to other models like decision trees, SVM has a very low chance of creating overfitting models. Sometimes, we may have to deal with imbalanced data, in that case, SVM is an ideal choice for that.

(Tomas, 2017) used Naïve Bayes, Random Forest Decision Tree, Support Vector and Logistic Regression classifiers in their paper to solve multi-class classification tasks. A workflow model was developed to first compare Naïve Bayes, Random Forest, Decision Tree, Support Vector Machines, and Logistic Regression classifiers having reviewed the comparative work of (Joachims, 1998), (Dumais, 1998) and other authors that Support Vector Machine is one of the best classifiers and has been recommended by many researchers, compared to that of Decision Tree or Naive Bayes. The findings from the comparative investigation in that paper indicated that the Logistic Regression multi-class classification method considering their data set which is product reviews has the greatest accuracy and is spaciously distributed in comparison to other methods.

However, all the above machine learning methods learn by identifying patterns from extracted features. The model is usually presented features and if the best features

representing the data is not fed into the model or a major feature is left out, the model would not classify well. This makes learning heavily dependent on features. For big data, it is extremely difficult to find the best features to represent them. Therefore, the models can be made to learn both the features' relations and the features themselves with **deep learning.**

2.4 Review of Related Literature

In this section, prior studies concerning authorship attribution based on n-grams are examined. Each approach is evaluated based on its accuracy and its limitations are identified.

(Sujin,2019) analyzing short blog posts from 200 articles and performing n-gram analysis using dissimilarity measure for author gender classification with that 85% of the data sets for training and 15% for test found unigram had a 56% peak accuracy for unigrams, 61% for bigrams and 51% for trigrams. The research had a limited dataset and suggested further studies can improve their study accuracy by automating the data collection process to get more datasets and the use of more advanced classifiers.

(Alison, 2014) Utilizing 63,000 emails and 2.5 million words written by 176 employees from now-defunct American energy Enron, revealed that word n-grams can accurately attribute anonymous email samples thereby revealing the elusive concept of idiolect. James Derrick was identifies by this study as a professional writer focusing on words like, please and thank you. This made identifying this author with n-gram very easy. The sample sizes were increased each time to see the effect of sufficient training data and n-grams on the accuracy of their model.

When their sample size increased to 15% (70 emails, 535-875 tokens), the performance of bigrams, trigrams and four-grams were flawless, the model correctly attributed the author to Derrick. Unigram and six-gram also had a strong performance of 90% accuracy, while 5- gram had 80%. As the samples to be increased to 20% of Derricks emails, unigram to five- grams all achieved 100% accuracy with 6-grams having 90%.

Based on the findings presented, the four-gram measure emerges as the most accurate and dependable method for identifying Derrick as the author of the samples. While longer n- grams generally yield better results compared to shorter ones, the accuracy does not consistently increase with the length of the n-gram. Four-grams outperformed five-grams and six-grams. This suggests longer sequences may be less frequent than shorter ones.

The limitation of the study, however, is that their study considered a topic-based dataset making them almost conclude that shorter n-gram reflects more of the topics of the dataset than the author. This study however eradicated this limitation by getting datasets independent of topic.

(Fatma, 2020) The study considers a dataset of short ancient Arabic text consisting of two documents per author and the average length of each document was approximately 550 words. Then different authors wrote ten books. It was difficult to separate the data into training and test sets, so the n-fold cross-validation technique was implemented, using all the data for both training and testing. The dataset is divided into n partitions, referred to as folds, using a random process. One of the n partitions is set aside as testing data while the remaining n-1 partition is used for training. The classifier is then trained n times, each iterating a different combination of training and testing data. The results they got from using 5 K- nearest neighbour and character 4-grams were the best with 90.42% accuracy. This was the best among all other n-grams and features they used.

(Zhenhao, 2016) employed neural network model and proved it outperformed traditional models by comparing a feed-forward model with a well-constructed N-gram baseline method with Kneser-Ney. The effectiveness of the neural network was examined particularly on limited data. Compared to Kneser-Ney smoothing, a reduction in the perplexity of nearly 2.5%, an increase of 3.43% was also noted positioning the neural network approach as a state-of-the-art method while also demanding less data to train.

(Koppel, 2011) employed a similarity-based method in analyzing blogs consisting of 2000 words from a large group of users. The objective of the experiment was to assess the accuracy of the methods using cosine similarity on a substantial number of users. Despite utilizing the powerful n-grams feature, the accuracy score fell below 50%. While this score may not be deemed a failure considering the extensive user set, it remains insufficient to meet the standards required for legal acceptance.

(Nicole, 2019) This research using data from Twitter employs a combination of n-grams gotten with TF-IDF techniques, syntactic (punctuations count), idiosyncratic (peculiar errors to an author) and lexical features. Alongside three distance measures: Cosine, Euclidean and Manhattan to indicate how close two author's vectors are to each other. The minimum distance calculated between the vector of an unknown author and a set of know authors was used to identify the author of every unidentified author. Spanish and English language

authors were used. However, it was discovered that only the English language data were correctly attributed owing to the unavailability of enough Spanish data set to train the model. The study, therefore, due to the absence of Spanish or other languages data recommended that English Language be use consistently in such studies. An imbalance in the length of texts also affected the expected accuracy of their results.

The similarity in writing style between the authors suggests a likeness, leading to the potential that these closely related authors might actually be the same individual.

2.5 Summary of Reviewed of Related Works

In previous studies, Nicole (2019) and Koppel (2011) investigated the attribution of common authorship by employing distance measures such as Cosine, Euclidean, and Manhattan. These studies also recognized that the n-grams feature yielded the best results for identifying shared authorship. Koppel (2011) achieved an accuracy below 50% using the Cosine similarity measure, but this was subsequently enhanced by Nicole (2019), who utilized three accuracy measures and a larger dataset. However, both studies suggested that improving accuracy would require expanding and normalizing the dataset for future investigations.

Consequently, this research expanded the dataset by scraping Quora, an online platform that provided a larger collection of data for analysis compared to Twitter. Additionally, the dataset was normalized by utilizing frequency probabilities of each author's writing before inputting it into the perceptron model.

The article review also provided an overview of common classification models used for authorship attribution, including Naïve Bayes, decision tree, random forest, and support vector machine. It highlights the strengths and weaknesses of each model and the potential of deep learning models in learning both feature relations and the features themselves is mentioned.

2.6 Knowledge gaps

Authorship attribution is now a well-understood and thoroughly studied subject as have been demonstrated in this literature review. Authorship attribution is normally based on the availability of an existing model characterizing authors and their idiosyncrasies. To identify the writer of a document, the proximity between such document and the various models of authorship are compared. In common authorship attribution however, what we have is a set of

documents whose authorship may be fictitious. The challenge, therefore, is to determine clusters of these documents based on proximity to language models developed from each document. So, one of the objectives of this study is to determine ways by which this clustering can be achieved.

CHAPTER 3

3.1 Preamble

This chapter outlines the research procedures, the processes of data collection, data preprocessing, feature selection and the classification technique used to identify the common authorship of a number of text documents.

3.2 Problem formulation

The problem addressed in this project is the de-anonymization of authors on social media, language modelling is achieved by the n-gram feature, which involves breaking the text from each author into unigrams, bigrams and trigrams which is then used to train a perceptron model. The activation function of the perceptron model helps to classify the authors into two, thereby generating an optimal weight that was used to attribute the test documents. The study took a step further by moving from a classification problem with supervised learning to a clustering problem unsupervised learning by removing the activation function of the perceptron and measuring the distance between each document to see the ones that are of closer proximity and infer that these are most likely to be written by the same author.

N-grams

-Classification with perceptron- is good enough to achieve basic classification around authorship.

-Clustering: Classification is a supervised approach to machine learning. The supervision in classification is due to the availability of labelled information provided by humans. In common authorship attribution, however, the labels attached to documents can be assumed to be fake because a single author may be writing under several fictitious pseudonyms

3.3 Proposed technique

From the foregoing, the common authorship attribution problem may be viewed as a degeneration from supervised learning to unsupervised learning, in order words, from classification to clustering. The methodology of building clusters of true authors around classes of fictitious authors is the central problem of the study.

If the models of two assumed different authors produce an unusually high incidence of misclassification, we may suspect common authorship. The specific problem to be solved in this study, therefore, is to distinguish between misclassification due to imperfection in

language modelling and misclassification due to deliberate misinformation on authorship labelling.

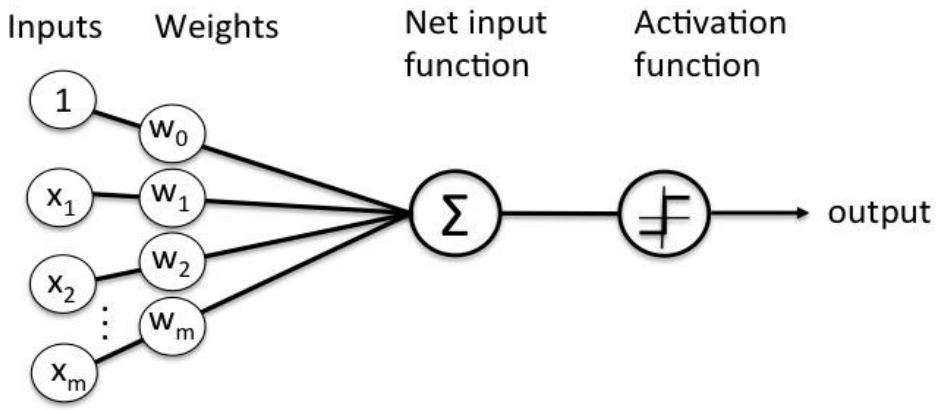
Converting a classification problem to a clustering problem may be achieved by the suspension of the activation function in the perceptron model thereby turning the classification problem into a regression problem. This is because the regression provides continuous rather than discrete values of the classification model. The distance between a document and the model of an author therefore can be determined by the regression rather than the classification model.

3.4 Tools Used in the Implementation

- Perceptron

  A perceptron is a unit (layer) of a neural network that contains two kinds of nodes, an input node and an output node. The name perceptron was derived from performing the human-like function of perception, seeing and recognizing images. Perceptron operates by inputting the data simultaneously with its weights, it then multiplies these corresponding data inputs and weights and sums its results to get a weighted sum. The input node transmits its resultant value to the outgoing link, the output node represents the model (Mayouk, 2023). The basic idea is that given input data, the model learns by repetitively calculating its error rates. Using this, it adjusts the weights to reduce the error rates and the outputs of the perceptron model are consistent with the actual output from the training data. When enough iterations have been done, the network represents a model that can be used to classify unseen data.

Fig.3.1 Illustrates what a perceptron may look like



Schematic of Rosenblatt's perceptron.

Output, $\sum = {}_0+w_1x_1+w_2x_2+w_3x_3+\ldots\ldots\ldots+w_mx_m$

Perceptron obtains its discreet output with the help of activation function. Sigmoid and Relu activation function are commonly used on perceptron.

- Web scrapper

Web scraping is the process of extracting data from websites. This project made use of Selenium as a scraping tool for retrieving data from Quora. Beautiful Soup was first explored to scrape Quora, however, being a scrapper for a static website it could not be used for this study. Selenium is a powerful tool for automating browser interactions was used by installing selenium and a chrome driver.

Quora, a social forum which was created on June 25, 2009, is a question-and-answer platform used by over 300 million users per month with a large growing knowledge archive. It is a good platform for natural language data analysis for various reasons:

- Quantity of Dataset: The vast number of users on this platform generate numerous contents from their million questions and answers covering a wide range of topics. This will help to provide more than enough datasets to train our model.

- Quality of data: Quora data is better well-written and structured than other social media sites. This makes the data easier to process and analyze the dataset from this platform.
- Subject-specific dataset: This project considers the influence of subjects on an author's writing style. Datasets from Quora are easy to analyze as the platform already grouped the questions and answers into their related topics like politics, Religion, Africa, Nigeria etc.
- No Word limit: Unlike some social media platform, Quora allow its users to provide detailed and comprehensive answers rather than short, superficial answers. This is especially helpful to this research as more text on a particular question helps to better depict the characteristics of an author's style compared to short posts from Twitter and the likes. A user's writing style can be lost if they are forced to distil their point into clear, short and concise statements. Cybercrime (Trolling) is more potent when a user has a lead way to advance an argument that micro-blogging site will limit. Advancing the information helps to ensure the real opinion is captured.
- Accurately labelled data: Information credibility is a pending challenge on the internet, with a popular example of users who intentionally post fake reviews about products, organizations or business in general. Such reviews could extremely affect a business positively or negatively. Quora as a website for knowledge sharing is unlikely to breed users who mask to share this knowledge.
- Programming Language (Python)

Python programming language was an excellent tool for various aspects of the study, including web scraping, programming the perceptron and evaluation. This tool was used to generate wordlists and n-grams, as well as the probabilities of their occurrence in a given text.

3.5 Technique(s) for the proposed solution

Figure 3.2: Proposed framework for this project

The procedure in the proposed technique

1. Collect the Data from Quora.

2. Apply preprocessing techniques to the documents such as case lowering, and removal of special characters.

3. Generating vectors from the text called tensors

4. Normalize the document

5. Divide into Training and Testing Data

6. Perform Perceptron Training till all training samples are correctly classified

7. Perform Testing using the Final Updated Weights.

8. Check performance through Confusion Matrix

3.6 Research Design Including Research Process Unified Modelling Language (UML)

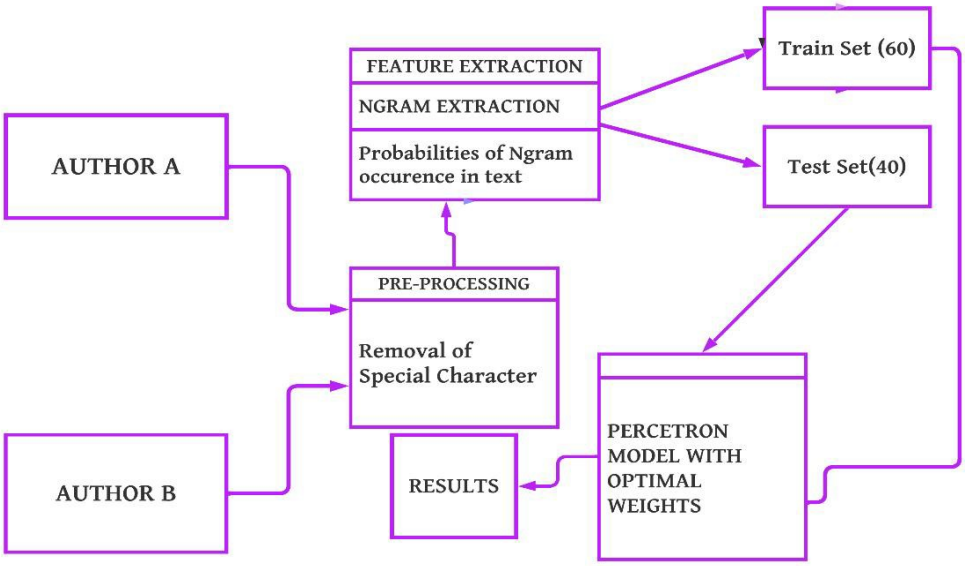


Figure 3.3: Proposed framework for this project

Computational authorship attribution is dependent on the dataset type in terms of the number of candidates for training and the amount of training data available per author. The performance of attribution models is usually improved by getting sufficient data for training the model. The raw data for the model has to be separated into two parts; the testing data for validation and the training data for learning. Training data is for the classifier to learn and testing data is used to justify the experience the classifier has learnt from the training data.

.

Dataset Collection

- Identification

Quora usually hosts a user's profile, questions, answers, comments, numbers of followers, numbers following etc. Therefore, this project identified a user's Quora answers which give room for getting the lengthier text as its dataset.

- Inspection

The source code of the Quora pages was inspected using the browser developer tool. This helps to identify the specific HTML tags to extract our data from

- Scraping code

Web scraping is done with Python libraries such as beautiful soup, Scrapy and Selenium. This project started off using beautiful soup to parse the data gotten from the URLs but the output kept giving an empty list. This was challenging because Quora is a dynamic website that adds its contents dynamically using JavaScript. To scrape Quora, selenium a web automation tool was employed to control a web browser and interact with its dynamic web pages.

- Store the data

A text file was created automatically from the Python code to store the scraped data.

- Quora's policies

All the above processes were done in compliance with Quora's terms of service and policies for scraping data, not using scraping to harm Quora or its users and to avoid overloading the servers with requests.

Figure 3.4: Extract from Quora dataset

Data Pre-processing

Natural language processing is a branch of artificial intelligence that studies, processes and retrieves information from human natural languages like text data (Oracle, 2023). Data preprocessing which can be called text preprocessing here because our data is in a text form, is a means of cleaning the data and making it ready to be fed into the model.

i. Lowercase**:** making the text the same case makes it easier for the model because the lower case and upper case are treated as two different texts by the computer. For example, Go, gO and GO will be treated like three different words. Therefore, we need to make the text in the same case and the most preferred case is a lower case to eliminate such problems.

```
txt =txt . lower()
```

Figure 3.5: Python code for lowercase

ii. Removing Punctuations and special characters

Punctuations and special characters as seen in the list in the code are replaced with an empty string.

```
specharr= [ ",", "?", "-", "“", "”", "!", "(", ")", "-", ":", "‘", "’", "•",
"*" , "_", ";", "/", "@", "•"]
        for char in specharr:
            txt =txt . replace( char, "" )
```

Figure 3.6 Python code for removing special characters

iii. Encoding text: The data is converted into numerical vectors using machine learning techniques. This project employed the frequency of each word and stored that in a Python dictionary. A word is the key, while the frequency of that word in a text is the value. Machines will not understand words, they need numbers so the project converts text to numbers in an efficient manner.

iv. Text normalization: resizing the numerical values of data so that they can be compared on a common scale. This report normalized the text document from the different authors making them easily comparable.

Split the data: The data was grouped into 60:40 training, testing for model development and evaluation.

Feature Selection and Extraction

Feature selection helps to identify the most relevant and insightful features selected for training the model. This study tokenized text into individual units of n-grams. For example, the girl sat on the chair. “The girl sat”, girl sat on”, “sat on the chair” analyzing the frequency of n-grams in text.

Perceptron Model

The model was trained the perceptron model as discussed in 3.4 to generate the optimal weight, then feed the model with the test data.

3.7 Description of validation technique(s) for proposed solution

The proposed methods for authorship attribution were validated using a specific approach. The data set, consisting of 100 text documents per author, was divided into two subsets. The division was done in a 3:2 ratio, meaning that 60 text documents from each author were used for training the perceptron model, while the remaining 40 text documents from each author were kept for testing.

During the training phase, the perceptron model was trained using the 60 text documents from each author. This process involved extracting the probabilities of ngram features from the texts and using them to train the model to learn patterns and characteristics specific to each author's writing style.

After the training was completed, the 40 test documents from each author were utilized to evaluate the efficiency and performance of the trained perceptron model. These test documents were not used during the training phase and were kept separate to provide an independent evaluation of the model's attribution capabilities.

To assess the accuracy, precision, and recall of the perceptron attribution model, a confusion matrix was computed. A confusion matrix is a table summarizing the performance of a classification model this is done by showing the counts of true positives, true negatives, false positives, and false negatives. In the context of authorship attribution, the confusion matrix helps measure the model's ability to correctly attribute authorship to the test documents.

By analyzing the confusion matrix, various metrics can be derived. Accuracy represents the overall correctness of the model's predictions. Precision measures the sample of correctly

attributed authorship cases among the predicted cases. Recall, also known as sensitivity or true positive rate, calculates the proportion of correctly attributed authorship cases among all the actual cases.

The computed confusion matrix provides valuable insights into the model's performance, allowing researchers to evaluate the accuracy, precision, and recall of the trained perceptron model for authorship attribution.

Overall, the validation process described involved dividing the dataset, training the perceptron model using a portion of the data, testing the model's performance using the remaining data, and computing a confusion matrix to assess the accuracy, precision, and recall of the model. This approach provides a specific methodology for evaluating the proposed methods and understanding the efficacy of the perceptron model for authorship attribution.

3.8 Description of evaluation metrics

Accuracy is known to as the proportion of samples that a particular classifier properly classified, or as the number of correctly classified reviews to the total number of reviews. It's expressed as a percentage and derived from the confusion matrix.

The confusion matrix groups the classification results into four categories:

True Positive (TP): when both the real and calculated values are 1

True Negative (TN): when both the real and calculated values are 0.

False Positive (FP): when the real value 0 and the calculated value 1

False Negative (FN): when the real value 1 and the calculated value 0

Accuracy= TP + TN / TP + TN + FP + FN

Recall: Recall = $TP/(TP+FN)$

Precision: Precision = $TP/(TP+FP)$

The metrics obtained from the confusion matrix offer a comprehensive assessment of the model's effectiveness in authorship attribution. Through the analysis of these metrics,

including accuracy, precision, recall, and F1-score, one can thoroughly evaluate the model's capabilities and limitations in accurately attributing authorship.

3.9 System Architecture

A basic neural network architecture, perceptron was applied to learn the n-gram feature representations of each author's text. It does this by adjusting the weights depending on the set learning rate. The learning rate determines how the dividing line moves around while trying to find a binary distinction between the authors. More formally, Perceptron predicts the author of a text by using an activation function.

The activation function, represented as f(x) here, is used for determining the output of the perceptron based on the weighted sum, x. For linear classification, a step function is employed activation, which can be described as follows:

f(x) = { 1, if x is greater than 0, otherwise

f(x) = { 0

The threshold is a predefined value that determines whether the output should be 1 or 0. It serves as the boundary that determines the perceptron's decision. Where x is the weighted sum of the **probabilities of n-gram occurrence in a document**, for a set of M documents, training involves adjusting the learning rate until a hyperplane classifies them into two.

The Probabilities of the occurrence of words in a text depends on the following factors:

1. Language of the text

The language of a document is a primary determinant of the probability of occurrence of a word in the document. This is due to the fact that the words used in the document will be drawn primarily from the vocabulary of the language in question.

2. Subject

The content words of a text are determined to a large extent by the subject that the text addresses. This is because a subject's terminologies are bound to feature prominently in the text. Subjects have varying vocabularies so we would not expect a text about politics to have the same frequent words as a subject about Religion.

3. First Language of the author

English has become an international language of businesses, and many countries keep coming in contact with it as international sales increase. Many of the best academic programs are taught in English, so learning to speak it well has become an aspiration for many as we all want to get the best training and credentials. However, idiosyncrasies often arise from translation and transfer, this is when non-native speakers of the English language try to translate words, phrases and grammatical structures from their first language into English. Also, collocations or words acceptable in the writer's first language also get to feature. Despite some similarities between different languages, there are a lot more differences. This makes the typical interpretation of statements like 'Good boy' in the English Language become 'Dada Omo' word for word against 'omo Dada' in the Yoruba language. Translation would have been somewhat easier if the interpretations were typical. A person's view of the universe and the people around them is closely linked with his first language. Mother tongue influences the way a person speaks other languages (English). This leads to **idiosyncrasies** causing many variances in the English Language.

Speech provides an easier identification using different acoustic cues for identifying the speaker's native language. However, to identify this cue for text **Error correction applications** like spell checkers, and grammar checkers can be used by authors to augment or reduce these errors. As a result, data that are not overly polished will be used in this project so that an author's natural repeated errors of all sorts can be found and used for their attribution.

4. Genre

Genre affects the probability of a word in a text. For example, in poetry where the choice of words is constrained by the quest for rhyme. William Berkely suggested that the poet 'Gentle Jesus meek and mild' that Jesus that could beat out traders in the temple is not mild. The mild here is just looking for rhyme. WhatsApp messages, a tweet, an email, an official letter, poetry etc. are different genres in which a user or author writes differently. Therefore, author A with a text document from emails should not be compared with author B with a text document from Twitter.

Social media is a relatively new phenomenon that now contributes a significant amount of data to written text. WhatsApp messages, tweetsetc. platform explores different parts of a user's vocabulary. The Twitter platform, for example, has a maximum of 280 characters

which will have an effect on the user's choice of words. In the user's effort to express their idea in as few characters as possible, the user is constrained to go for shorter words.

Email another social media platform, started as an informal means of communication. Today, however, it is generally used as a means of official communication. This transition must have had an effect on the types of words used in emails.

All these above factors are determinants for the probability of a word. However, some reflect authorship while others diffuse authorship.

CHAPTER 4

4.1 Preamble

In the study 100 of text documents were considered from two Quora authors to demonstrate the effectiveness and performance of the perceptron model for binary authorship attribution using the n-gram feature, comparing and evaluating their results. Additionally, we discuss the language idiosyncrasies caused by first-language interference on English Language.

Language Idiosyncrasies caused by first Language interference

As an extension to authorship attribution as generally treated in the literature, this project will consider also other key factors that may shed more light on the better features that represent an author's writing style to a model. The effect of a first Language, on English as a Second Language, be statistically accounted for and utilized as an authorship feature for authorship attribution. English as a second language users often misuse the article "the", this is because all languages have their rules and deviating from such rules may lead to inappropriate sentences. The rules governing every language often cause the second language learners of English to sometimes transfer the rules governing their own language into the second language they speak. Such transfers of constructions are regarded as language idiosyncrasies.

(Nkoli, 2020) gave instances of a sentence like 'The woman delivered a bouncing baby girl', a very common sentence among the Igbo speakers of English against the correct expression which is 'The woman was delivered of a bouncing baby girl'. The investigator further stated the reason being that the Igbo version of the sentence is 'Nwaanyị ahụ mụrụ agadaga nwa nwaanyị', which was analyzed is thus: Nwaanyị ahụ= The woman Mụrụ= delivered Agadaga= bouncing Nwa nwaanyị= A baby girl Altogether we have: The woman delivered a baby girl.

Nigeria as this project's case study has English as a second and official language serving the purposes of classroom-based instruction, and that of Lingua-Franca.

Nigeria was suggested by (Muhammad, 2020) to have various minor languages of about 395-396 aside the three major languages known as Yoruba, Igbo and Hausa. Owing to this reason Nigerians find it difficult to accept one of the three major languages as an official language and after accepting English as its official language encounters various error in its mastery. The author also noted that this is not only peculiar to Nigeria but to other countries with similar settings. Nigeria as this project's practical case study was identified with her learners'

committing errors in the process of constructing sentences, writing mechanic or in situating grammatical functions. An Ethnic group under Yoruba, the owo language common errors was analyzed in (Olaleye, 2016). The paper revealed the various idiosyncrasies;

1. The use of stative verbs. This means perception, cognition and relations such as see, hear, notice, understand, know, have etc. These verbs are not used in a progressive manner. However, overgeneralization makes the second language speakers of English language use them in the progressive tense. Constructing sentences like:

- I am seeing you from the Fifth floor. (can see)
- I am still hearing you (can hear)

2. The use of Dynamic Verbs

Dynamic verbs represent activity or physical actions. Some examples of deviant usage by Nigerian students.

- NEPA has taken light. (has interrupted electricity supply)
- NEPA has brought light. (has restored electricity supply)
- Please, on/off the light. (Switch on/off)
- Can you borrow me your book? (lend)

3. Deviant Use of Reflexive Pronoun

Nigerians do not differentiate between “themselves and ourselves”, “each other and one another”. This is owing to the fact that in the Nigerian Languages like Yoruba and its dialect only has one lexical item ara wa/ara won which corresponds to ourselves/themselves, one another/each other. Thus, expressions are found in Nigerian English.

- They love themselves. (each other)
- After greeting ourselves (one another)
- They like helping themselves. (one another)

4. Use of Personal Plural Pronoun for Singular Reference

The source of this type of deviation can be linked to the transfer of the pronoun awon in Yoruba this connotes respect for elders. “Awon” then translates to they in English. For example,

- “I heard they travelled to Lagos”- They here refers to a single person (an elder person to the speaker)

5. Use of Redundant Words in Sentences: Tautology

This error style adds needless words a speaker’s statement, or content. For instance,

- Funmi had returned back from Lagos
- Do the work quick quick
- Am going there now now

6. Omission of Determiners

Determiners include words like articles, quantifiers and demonstratives. They usually come before a noun to show the reader if the noun is specific or general such as “That dress” and “a dress”

As already said, all these features can be statistically accounted for.

Authorship Attribution with Perceptron

A text document with a .txt file extension was created to store the scrapped answers and save them with the respective authors of the document. Single layer perceptron, a binary classifier is employed to classify two authors with their text with target classification labels as 0 or 1. The model steps are highlighted below:

1. Perceptron Input

As stated in chapter 3 of this project, Quora was scrapped to get a text document of the authors. In this experiment, Robert and Theophilus’ documents were used. Robert is a USA English writer and Theophilus is a Nigerian English writer. The train set of their text files was imported as input to the perceptron with labels 0 or 1.

2. Introduce the weights

The weight of each word in the document was retrieved and stored in a Python dictionary by finding the probability of each word’s occurrence in the form of unigram, bigram, trigram and n-gram. All weights and inputs are then multiplied using:

$$\text{Output, } \sum = {}_0+w_1x_1+w_2x_2+w_3x_3+\ldots\ldots\ldots+w_mx_m$$

3.Learning rate

A bias value called learning rate is added to shift the output function. It's a constant value added to the input and weight product. For cases where the input is 0 (zero) and we want out neural network to return a value. The learning helps to ensure this.

1. Activation Function

The value gotten is presented to the activation/step function which will be calculated as the final prediction of the Neural network. Activation functions help to classify the data easily. The sigmoid function is used for values between 0 and 1.

```
def calcy(dic, weights_dic):
    ycalc=0
    for word in dic:
        ycalc+=weights_dic[word]* dic[word]

    if ycalc < 0:
        ycalc=0
    else:
        ycalc=1

    return ycalc
```

Figure 4.1: Python code for the activation function

4.2 System Evaluation

To evaluate this project, two types of attribution models: The Classification model (supervised learning) with binary classification and the clustering model (unsupervised learning) with logistic regression to identify common authorship. N-gram language modelling was applied to these models, analyzing the effect of learning rate modulation and increase n- grams. Nigeria authors were used to represent the country with second-language speakers of the English language. Finally, in investigating the effectiveness of the models.

Furthermore, the limitations of these approaches and possible directions for future work were presented.

4.3 Results presentation

This section shows results and training time for the perceptron models used with varying learning rates and n-grams. The social platform dataset was split into training and test samples in the proportion of 60:40, respectively.

PERCEPTRON CLASSIFICATION

Experiment 1:

The first experiment was based using probabilities of unigram, bigrams frequency with varying learning rates and data size as shown in the tables below, Author A: Theophilus was given a label 0 and Author B: Mmabuechi a label 1.

Unigram

Learning Rates	Correct Attributions	Wrong attributions	Total Number of Train Documents	Total Number of Test Documents	Training Time
0.1	61	19	120 (60 per author)	80 (40 per author)	25 mins:22secs
0.5	54	26	120 (60 per author)	80 (40 per author)	13mins:01sec
0.05	75	5	120 (60 per author)	80 (40 per author)	14mins:55secs

Table 4.1: Unigram Perceptron Model for Authorship Attribution

Bigram

Model Building process

The model-building process consists of 100 documents from two authors scraped from the answer section in Quora with little or no controversial topics. Hence, straightforward factual answers are expected from the authors as much as possible. This is in contrast to sites that host political debates and other contentious issues that may encourage trolling and the use of pseudonyms. It is expected therefore that the authorship labels given to the documents are actually truthful. N-grams probabilities of these documents were built into a language model. The models were subjected to evaluation testing by the use of documents outside the training document. The training of the models took on an average of 30 minutes per epoch and in documents in excess of number of bigrams took about 22 to 60 epochs.

Whereby, 60* 30= 1800 minutes

This was a major problem encountered in this study, the challenges and proffered solution are further discussed in Chapter 5.

4.4 Result Analysis

The experiment presented in this report focuses on the application of unigram and bigram models using a perceptron algorithm for authorship attribution. The authors, labelled as Author A (Theophilus) and Author B (Mmabuechi), are assigned labels 0 and 1, respectively. The experiment aims to assess the performance of the models with varying learning rates and n-gram

Unigram Model: The unigram model demonstrates relatively shorter training time across different learning rates. The learning rate of 0.05 achieves the highest accuracy, with 75 correct attributions and only 5 wrong attributions in under 5 mins. This indicates a strong ability to correctly attribute authors based on the given text samples. The attribution done with 0.1 and 0.5 had 19 and 26 wrong attributions respectively.

The precision and recall metrics provide further insights into the performance. Precision represents the proportion of correctly attributed samples among all samples predicted as belonging to the respective author. In this case, the precision ranges from 0.704 to 0.949. The recall represents the proportion of correctly attributed samples among all samples that should

have been predicted as belonging to the respective author. The recall values range from 0.704 to 0.925, indicating an ability to capture the texts from both authors.

Bigram Model: The Bigram model shows varying performance across different learning rates. The learning rate of 0.5 achieves the highest accuracy, with 74 correct attributions and 6 wrong attributions. This indicates the model's ability to distinguish between the two authors but with slightly higher accuracy compared to the unigram model.

The precision and recall metrics also vary across learning rates. Precision ranges from 0.9 to 0.947, indicating reasonably high precision in correctly attributing texts to the respective authors. Recall ranges from 0.9 to 0.95, suggesting a good ability to capture the texts from both authors.

Comparison between Unigram and Bigram Models: Comparing the two models, the Bigram model consistently outperforms the unigram model in terms of accuracy, precision, and recall across 0.1 and 0.5 learning rates. This suggests that the bigram model may be better suited for authorship attribution in this specific context. However, the unigram model still achieves reasonable accuracy and performance, indicating its potential usefulness in certain scenariozs.

Experiment 2: the labels for the authors wee reversed, making Author A (Theophilus) have label 1 and Author B (Mmabuechi) have label 0. This to assess the impact of label reversal on the performance of the models.

The results for the reverse unigram model show a better performance to the initial experiment, with accuracy ranging from 70% to 98.75%. Overall, the Bigram models perform better than the Unigram models in terms of accuracy and precision. The Bigram model with a learning rate of 0.1 achieves the highest accuracy of 98.75% and perfect precision. However, it is worth noting that the Bigram models require significantly more training time compared to the Unigram models.

4.5 Discussion of Results

DELIBERATION 1: Why then can we not keep increasing n to get better accuracy?

This study wanted to explore training the perceptron with trigrams also. However, due to the inaccessibility of High Computing as discussed in Chapter 5 had to put a stop at the bigram. Also, from research, a larger n is able to capture more structural information because a bigram captures the last word and the next word while a trigram goes further to account for

the relationship between the last two words and the next word. However, when the n is too large it leads to computational complexity.

DELIBERATION 2: Why does the classification get affected by learning or how do learning rates affect classification?

Learning rate is a tuning parameter in our perceptron model that determines the step size at each iteration while moving toward the classifying line.It represents the speed at which the model learns. While training the model, the learning rate plays an important role in determining how quickly or slowly the model converges i.e. adapts and updates its weights during the learning process. A learning rate can be too large and cause the model to overshoot its objective thereby unlearning what it has learned. Also, there comes a point at which reducing the learning rate beyond a threshold also wastes time, resulting in taking many more steps than necessary to reach a diving line.

It is important to note that the ideal learning rate is problem-dependent and may require experimentation to find the optimal value. A learning rate that is too high may cause the model to converge quickly but with suboptimal weights, leading to lower accuracy. Conversely, a learning rate that is too low may result in very slow convergence or the model getting stuck in a suboptimal solution.

It is essential to strike a balance between convergence speed and stability by carefully tuning the learning rate based on the specific characteristics of the dataset and the desired trade-offs between training time and model performance.

4.6 Benchmark of the results

In this benchmark analysis, the performance of the perceptron model for authorship attribution is compared with previous methods that have been commonly used in the field. The goal is to evaluate the effectiveness and advancements offered by the perceptron model in attributing texts to their respective authors.

Methods Comparison

Perceptron Model: The perceptron model is a simple algorithm that learns to classify texts based on extracted linguistic features. It iteratively adjusts weights at a learning rate to improve classification accuracy. The previous methods traditional approaches such as

stylometry, n-gram models, and machine learning algorithms like support vector machines (SVM) or decision trees. Stylometry focuses on statistical analysis of textual features, while n-gram models capture patterns of consecutive words. Machine learning algorithms use features extracted from the texts to train classifiers for authorship attribution.

This study's perceptron model offers:

Simplicity: The perceptron model is relatively simple compared to some traditional methods and machine learning algorithms. Its straightforward implementation and training process makes it accessible and efficient.

Generalization: The perceptron model demonstrates good generalization capabilities, allowing it to attribute texts accurately across different genres, languages, or writing styles. This is a significant advantage, particularly when dealing with diverse datasets.

Adaptability: The perceptron model can adapt to new authors or datasets with minimal retraining. It can quickly incorporate new data, making it suitable for real-time authorship attribution applications.

CHAPTER 5

5.1 Summary

Authorship attribution is a field of study that aims to determine the author or source of a given text. In this report, we explore the application of perceptron models for authorship attribution, which involves training a model to learn the unique writing styles and patterns of different authors. The perceptron model, a simple yet powerful algorithm, allows us to classify and attribute texts based on their linguistic features.

To build an authorship attribution model using Perceptron, we followed these steps:

Dataset Collection: We gathered a dataset consisting of texts written by various authors across different genres or domains. This dataset serves as the training data for the perceptron model.

Feature Extraction: From the collected texts, we extracted a set of relevant linguistic features, such as word frequencies, sentence structures, punctuation usage, or syntactic patterns. These features capture the distinctive writing style of each author.

Training the Perceptron Model: We divided the dataset into training and testing subsets. We trained the perceptron model using the training subset, adjusting weights and biases iteratively to minimize errors. The perceptron learns to differentiate between authors based on the extracted features.

Evaluation: We evaluated the performance of the perceptron model using the testing subset. Metrics such as accuracy, precision, recall, or F1 score were calculated to assess the model's effectiveness in correctly attributing texts to their respective authors.

Results: Our experiments with the perceptron model for authorship attribution yielded promising results. The model demonstrated strong performance in accurately attributing texts to their authors. The evaluation metrics indicated high accuracy and precision, showcasing the model's ability to learn and generalize from the extracted linguistic features.

Discussion: The success of the perceptron model in authorship attribution showcases its potential for various applications. It can be used in forensic linguistics to identify anonymous authors of trolls. Additionally, the model's generalization capabilities allow it to handle different genres, languages, or writing styles, making it versatile and adaptable to various scenarios.

This is an exploratory study to establish that identification of common authorship is possible and perceptron as the most basic approach was used for two reasons.

1. Limited availability of sufficiently fast hardware
2. If the most basic approach works, then the more theoretically robust approaches will not only work but produce much better results.

5.2 Conclusion

In conclusion, the perceptron model for authorship attribution performs competitively compared to previous methods. It offers accurate attribution, balanced precision and recall, and demonstrates generalization capabilities. The simplicity, adaptability, and efficiency of the perceptron model make it a valuable tool for authorship attribution tasks. As technology continues to advance, the perceptron model holds great potential for further improvements and applications in the field of authorship attribution.

5.3 Challenges Encountered and Recommended Solution

This study is an exploratory study to investigate the viability of common authorship attribution. Therefore, the perceptron which is one of the most basic classification tools in artificial intelligence, was used as a starting point. It was assumed that if the perceptron yielded positive results, more advanced classification tools like Support Vector Machines, neural networks, and deep neural networks would even be more effective.

Due to the computational demands and time constraints, the study had to focus on unigram and bigram analysis instead of exploring trigrams and n-grams with the perceptron. Trying to train the perceptron with trigram took more than 5 days to no avail. The processor speed of my 8GB RAM, 1Terabyte Hp Laptop was not sufficient to do this. This limited the capacity for experimentation, even as the most basic tool was used. For that reason, the study had to be stepped down to just the unigram and bigram. Then a compromise was made because the bigram that took a short time had a higher level of misclassification, this is owing to the effect of the learning rate on accuracy as discussed in Chapter 4.

I had challenges in accessing high-performance computing facilities in Nigeria. Although a Graphical Processing Unit (GPU) was obtained through the Africa Language Technology

Initiative (ALT-I) provided by my project supervisor, Dr Tunde Adegbola. However, it was not supported with a robust enough uninterrupted supply. It was on a desktop so whenever power is interrupted it loses data and the program restarts all over. This led to devising a means to modify the program such that at each training epoch, the instalment weights are recorded. So that when power is restored the last weight is fed back or copied to my PC when the duration for restoration is too long. This is slower but it accelerates before power restoration.

Although having used the perceptron and getting 95% accuracy I have assurance that the more rigorous ones will perform better once the high-performing systems are made available. Only the training time suffers the need of a high-performing system, the testing time is very minimal

To be able to further this study and even publish papers, I recommend that ACETEL considers acquiring GPU computers with long-term solar-powered inverter backup. Services can be procured from the cloud on some processors. Ultimately, high-performance computers can be acquired to aid Artificial Intelligence-related works just as done in ACE in the Benin Republic.

I recommend ACETEL considering Hardware-as-a-Service (HaaS) as a solution to address the lack of high-performing computers for your artificial intelligence related projects or the ACETEL programmes at large. HaaS is a cloud-based service that allows one to access and utilize powerful hardware resources without the need to invest in expensive infrastructure. It provides a cost-effectiveness i.e., instead of purchasing high-performance computers upfront one can just pay a subscription or usage-based fee. It gives access to the latest technology.

5.4 Contributions to Knowledge

Here are some key contributions this study has made to Cyber security by attributing trollers :

Identifying Trolls: Trolls often hide behind anonymity or use multiple pseudonyms to engage in disruptive behaviours online. By analyzing linguistic patterns, writing styles, or other textual features, a perceptron model can help identify consistent trolling behaviours across

different platforms and accounts. This enables the early detection and recognition of potential trolls, allowing for targeted intervention and prevention strategies.

Tracking and Monitoring: Perceptron models can be trained to track and monitor the online activities of known trolls or individuals with a history of engaging in trolling behaviour. By identifying their distinct writing styles or patterns, the model can flag and alert moderators or administrators when such individuals engage in trolling across various online platforms. This proactive approach helps in reducing the spread of toxic behavior and enables prompt intervention.

Automatic Filtering and Moderation: By utilizing the learned knowledge from a perceptron model, online platforms and social media networks can implement automatic filtering and moderation systems. These systems can identify and flag potentially trolling or abusive content, enabling moderators to review and take appropriate actions. By reducing the visibility and impact of trolling behaviour, these systems create a safer and more constructive online environment.

User Reputation Systems: A perceptron model can contribute to the development of user reputation systems that evaluate the trustworthiness and credibility of individuals in online communities. By considering factors such as writing style, consistency, and history of trolling behaviour, the model can assign reputation scores to users. This helps in distinguishing between genuine contributors and potential trolls, fostering positive interactions and discouraging trolling behaviour.

By leveraging perceptron models for authorship attribution and profiling, we can significantly contribute to preventing trolling by identifying trolls, tracking their activities, implementing automated moderation systems, establishing user reputation systems, developing tailored intervention strategies, and fostering public awareness. These contributions aim to create a healthier and safer online environment by reducing the occurrence and impact of trolling behaviour.

5.5 Future Research Directions

It was observed as predicted in theory that the leaning rate affected the accuracy of the model. However, the effect of the learning rate on the accuracy was not really predictable. This can be understood from the fact that the effect of the learning rate on the accuracy depends on the

distribution of the data which in itself may not be predictable. It is known that the support vector machine as a matter of course always produces a classification model with the optimal accuracy. In future studies therefore, the use of the support vector machine and neural networks instead of the perceptron should be considered.

Future research can explore training a perceptron with trigrams and more n-grams to see the effect of increased gram on accuracy. Also, neural networks and deep learning can further be explored to attribute trollers or online criminals at large. There is a potential of achieving 100% accuracy with this, since 98.75% was achieved with a perceptron trained with Bigrams.

Project Supervisor Recommender System for Students: A Machine Learning Approach

Stanley Abiodun METIBOGUN (ACE21130013)

M.Sc. Management Information System

A Thesis submitted to the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), in partial fulfilment of the requirements for the Award of Masters of Science Degree in Management Information System.

Department of Management Information System, Africa Centre of Excellence on Technology Enhanced Learning, National Open University of Nigeria.

October, 2023

DECLARATION

I hereby assert that the research work presented in the Thesis, titled "Project Supervisor Recommender System for Students: A Machine Learning Approach," is an original piece of research work towards the fulfilment of the requirements for the award of Masters Degree in Management Information System. This thesis has been submitted to the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL) at the National Open University of Nigeria. The research was conducted under the supervision of Dr. Ibrahim Abdullahi and Dr. Usman Ali, both of ACETEL at the National Open University of Nigeria. The text appropriately acknowledges the information obtained from the sources cited, and a comprehensive list of references is also included. The content included in this Thesis has not been previously submitted by me for the purpose of obtaining any other degree from any other academic institution.

Stanley Abiodun Metibogun		30-10-2023
Name of Student	**Signature**	**Date**

CERTIFICATION/APPROVAL

This thesis titled "Project Supervisor Recommender System for Students: A Machine Learning Approach" complies with the regulations for attaining the Master of Science degree at the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), National Open University of Nigeria. It has been deemed acceptable for its significant contribution to knowledge and its adherence to standards of intellectual presentation.

Dr. Ibrahim Abdullahi	……	15/12/2023 ……
Main Supervisor	Signature	Date
Dr. Usman Ali	……	……
Co-Supervisor	Signature	Date

DEDICATION

This research is dedicated to my amazing family. Thank you for the show of love and support.

ACKNOWLEDGEMENTS

What more can I say than give honour to God, who deserves all the glory? For someone who could have passed on just two weeks before the first session's first semester exams. That itself is a story on its own. It is for this reason I'm thankful I didn't just begin, but I finished well.

There is a saying that people come into our lives for a purpose. I am thankful to have met incredible and outstanding individuals along my academic path, who have left indelible impressions on me for which I will be ever grateful. My main supervisor, Dr. Ibrahim Abdullahi, and his co-supervisor, Dr. Usman Ali, will be remembered for their enormous contributions during our class facilitations and research work. They assisted me in putting my thinking faculties together to create amazing problem-solving concepts that were exhibited in the research work. They were both crucial in giving direction, mentorship, and resource materials. Despite his busy schedule, Dr. Ibrahim would always arrange for us to meet in person in Abuja.

As ACETEL pioneer students, we often had issues that needed to be answered, and our outstanding coordinator at the ACETEL, Management Information System Department, Dr. Juliana Ndunagu, was always available at any time to give advice and clarifications. Thank you, Ma.

I say a big thank you to all ACETEL facilitators, particularly those from the Management Information System Department, for imparting life-relevant information and experience that will forever be remembered. Thank you to everyone who offered constructive criticism, encouragement, and suggestions to back up my facts and findings during my research proposal presentation. I carefully considered your feedback and used them at the appropriate places, which is reflected in the final work. I'm sure you would be proud I did. Thank you very much. To the staff of ACETEL who have made our journey smooth especially in offering consultations, organizing online meetings for staff and student interactions, etc., you are all loved. I'm also saying a big thank you to my MIS, M.Sc. colleagues for the interactions and idea-sharing.

To my family and parents, Mr. and Mrs. Metibogun, thank you for your role in my educational journey. I'm expressing my heartfelt appreciation for your efforts, which I do not take lightly. To my incredible Asiwaju and amazing Mayowa, you are my biggest inspiration for this work. Even when you weren't physically there, you always cheer me up. You are the best.

ABSTRACT

Project supervisor selection in academic institutions plays a significant role in the overall output of a student's research. The selection procedure can be manual, automatic, or hybrid. The manual process has several attendant drawbacks. Automating the selection process does not necessarily have to follow the traditional search and filter methods of document filtering. Supervisors' past scholarly articles are already loaded with relevant keywords and data that can harnessed for decision-making in selecting project supervisors for students. Machine Learning, an Artificial Intelligence component that learns from data without being explicitly programmed, and Natural Language Processing (NLP) comes in handy in this case for intelligent Decision Support System (DSS). Following the Cross Industry Standard Process for Data Mining (CRISP-DM), preprocessing and processing tasks were executed on extracted data from potential supervisors' Google Scholar publications for clean data and best results before feeding them into the recommendation engine. This research examines a content-based information filtering recommendation system that compares student project proposal data to a pool of possible supervisors' Google Scholar research publications using the Cosine Similarity algorithm. The system utilizes a Machine Learning-powered recommendation system to provide a list of best-match project supervisors. It employs Python-based Django Web Framework's Model-Template-View (MTV) architecture and Cosine Similarity metric in its machine learning algorithms. In addition to automating the manual selection process, this efficient and effective recommendation system maintains its competitive edge through its speed of execution, capacity for enhanced intelligence with expanding data, and potential to ultimately improve research performance by leveraging the shared interests of students and supervisors.

CHAPTER 1 – INTRODUCTION

1.1 Background to the Study

A Final-Year student project remains a fundamental academic task that students must accomplish in an educational institution, whether on a postgraduate or undergraduate level, to demonstrate the skills and knowledge acquired during their academic studies. Project supervisors are appointed or chosen for students primarily for supervision and facilitation to get the most out of academic research. Automating the decision-making process in project supervisor selection is a typical example of Decision Support System (DSS) implementation. DSS improves an organization's efficiency and decision-making speed without human bias. A decision support system is essentially an information system that helps a business make decisions that call for judgment, determination, and a series of actions to support the decision-makers but not necessarily to replace them (Maria, Maryam, Bijan, & Masoud, 2018).

The process of assigning academic project supervisors to final-year graduating students in most Nigerian academic institutions is carried out manually without input from students and lecturers (Yahaya, Abubakar, & Muhammad, 2023). Similarly, the pioneer students and lecturers of ACETEL were also caught up in this norm. Therefore, finding a technology solution strategy becomes essential, necessitating this research in applying Artificial Intelligence (AI) to develop a research supervisor recommender system to recommend the best-fit supervisor for students using Machine Learning.

Recommendation Systems are an essential class of Machine Learning that tries to identify the patterns of human behaviour, especially decision-making and use them to predict results or items that are most pertinent to a particular user. In general, recommender systems act as information filtering tools, offering users suitable and personalized content to reduce the effort and time required to search for relevant information online (Roy & Dutta, 2022).

The three main types of recommender systems are content-based recommender systems, collaborative filtering recommender systems, and hybrid recommender systems (Ko, Lee, Park, & Choi, 2022). Popular services like YouTube, Amazon, and Netflix all have recommendation systems that suggest the next video or purchase based on one's browsing history (content-based) or the browsing habits of other users with one's interests (collaborative). Facebook, which suggests people you might know offline, utilizes a recommendation engine to suggest users.

A content-based recommendation system suggests various items comparable in content to the items that particular users are interested in or have previously liked or enjoyed. Collaborative filtering recommendation systems leverage user preferences to tailor a recommendation to a specific user. Here, the measure of user similarity is an indicator. On the other hand, hybrid approaches combine two or more techniques to solve the shortcomings of individual recommender techniques (Deschênes, 2020).

The similarity of the contents or the users who access the content is the basis on which recommender systems operate. Such similarity between two items can be assessed in various ways. Recommendation systems employ this similarity matrix to suggest the next most similar item to the user (Kilani, Alsarhan, Bsoul, & El-Salhi, 2018).

This research intends to create a recommender system using the Cosine Similarity Matrix to match final-year project students with possible project supervisors based on the students' submitted project topics, abstracts, and keywords. Data from the publications listed on Google Scholar profiles of ACETEL lecturers were extracted and utilized as our foundation dataset. Authors, titles, abstracts, and keywords are among the information extracted from the online publications used in this research.

1.2 Statement of the Problem

- The current system of final-year student project supervisor selection in a typical Nigerian academic setting and, by extension, ACETEL does not take into consideration students' project proposals, lecturers' areas of interest or specializations, and other necessary research-boosting factors before assigning project supervisors to students. Sometimes, students do not even have a basis for their chosen research area, and speculations mostly dominate their motivation. Many students end up with project topics they are either not interested in conducting research on or supervisors not interested in supervising, which ultimately affects productivity.

- By default, ACETEL pioneer students did not have predecessors or seniors who had graduated from the institution from whom to get project recommendation ideas and learn.

- Most students were only familiar with lecturers who had taught them in previous semesters but were unfamiliar with other lecturers in the faculty because they had never had contact with them, neither with their academic publications nor are aware of their specializations.

- In addition, the inefficiency of the manual selection process, which is often not void of human bias, also raises concern for the students' project supervisor selection process.

However, with recent advancements in data science and pervasive computing, recommender systems, which are increasingly being used in a large number of applications like movies, e-commerce, books, web search, and specialized research resources, can now be tailored to automate the project supervisor selection process. This research seeks to fill these identified gaps by building a content-filtering Machine Learning model of recommender systems to match student project proposals with the most suited potential project supervisors who can provide guidance, mentorship and possible facilitation.

1.2.1 Research Questions

In as much as this research seeks to explore and explain the application of cosine similarity to predict potential project supervisors for graduating students with a content-based technique of recommender systems, it also seeks to answer some salient questions:

- Is Cosine Similarity an effective approach project for project supervisor recommendation system?
- How do you evaluate the accuracy of cosine similarity?

This research goes further to transform the extracted research publications of lecturers and students' research proposals into vectors and apply similarity measures between these text representations to recommend project supervisor(s) that satisfy the notion of proposed research similarity with past research publications of lecturers. A representative dataset of sixteen lecturers' publications is used to investigate combinations resulting from one thousand one hundred and forty-one (1,137) publication representations and a similarity measurement utilizing cosine similarity. To validate this research question, we were able to establish that cosine similarity, as it were, is an algorithmic metric used in a variety of machine learning algorithms, including K-Nearest Neighbour (KNN) for calculating the distance between neighbours, in recommender systems for recommending similar movies, and textual data for determining the similarity of text in documents. With a statistically accepted baseline range of zero to one (0 to 1), we contrast the outputs of the model (cosine similarity). Distances decrease as similarity increases. When choosing a similarity threshold for texts or documents, a number higher than 0.5 often indicates significant similarities. In the literature review, some of the techniques engaged in the research were noted. Our findings also reveal that Euclidean distance produced fewer encouraging findings than content-based recommendations utilizing a cosine similarity matrix.

1.3 Aim of the Study

The aim is to create a recommender system that recommends project supervisors for students, complementing the institution's current project supervisor selection procedure.

1.4 Specific objectives

These specific objectives serve as action guides to achieve our aim.

1. To build a dataset from scholarly publications of selected lecturers with data extracted from the publications listed on their Google Scholar profiles.
2. To develop a suitable model with a text similarity algorithm that can be integrated into the system.
3. To build an interactive web-based application from the Machine Learning project that provides a user interface for inputting student project proposal data and displaying the resultant machine learning recommended project supervisor.

1.5 Scope of the Study

While the challenge of inefficiency in the manual selection of supervisors for final-year project students persists, automating the decision-making process remains a viable means of matching students with potential supervisors. This research aims to create a recommender system to suggest project supervisors for final-year students to automate the existing selection process with speed, efficiency, and accuracy without human bias.

Due to constraints in data collection and research duration, the scope of coverage of this research is limited to automating the project supervisor selection process of ACETEL's MIS Department. However, it can be broadened to include the ACETEL Faculty and institution. With the availability of big data infrastructure and resources, this academic research work can also be expanded and diversified into additional purposes that could be implemented in the form of distinct modules integrated into a full-blown robust application.

Recommender systems are basically of three types, i.e., content-based Filtering, collaborative Filtering, and a hybrid of content-based and collaborative. This research is focused on a Content-based Filtering (CBF) method. It is one of the most effective recommender systems based on content correlations. The similarities between items are determined by CBF using item data expressed as attributes (Son & Kim, 2017). Our content type is text-based, which includes the text of lecturers' research keywords, research titles, and research abstracts. Engaging the Cosine Similarity Matrix algorithm, we can measure the distance between inputted student proposals and lecturers' past research work to gauge how closely the sentences are related. The recommender is comparable to other recommender engine methodologies in terms of user profiles, item descriptions, and methods for matching profiles with objects to get the most relevant user suggestion results (Mohamed, Khafagy, & Ibrahim, 2019).
This research is a Machine Learning undertaking incorporating Natural Language Processing and Software Engineering with processes and procedures, including data gathering, data preprocessing, data processing, web application development and recommender engine development. It uses experimental research design as the quantitative approach to predict recommendation results. Our research approach in this study is quantitative, based on a review of relevant literature, empirical findings, and other factors indicative of the fact that our analysis involves data modeling using statistical analysis methods to test relationships between variables (Kamiri & Mariga, 2021).

1.6 Significance of the Study

i. This research work would aid the institution in making more informed and actionable decisions on project supervisor selection.
ii. Changes in project-related matters frequently occur, including project topic, research area, or project supervisor. The recommendation system comes in handy to provide multiple suggested results based on current and historical data.
iii. Students get more enthusiastic when their research area and topic match the supervisor's research interests, specialization or ongoing research work. This could breed improved facilitation by the lecturer. Ultimately, both the student and the supervisor may benefit from the enthusiasm, motivation and productivity.
iv. The recommender system can be extended to gather ACETEL students' projects and research publications, which could function as an Academic Research data repository from which further tech-driven innovations and data analysis can be carried out in the future.
v. Students can depend on reliable data from the Academic Research repository in addition to data sourced from classmates, lecturers and predecessors.
vi. It is a contribution to the body of knowledge from which further research can be carried out.
vii. It has the potential to generate revenue for ACETEL with a well-designed business model by transforming it into a technology research hub, serving as a meeting place for students and lecturers.

The platform can be built with the following in mind:
a. A platform for the generation of research topics and ideas.

b. A training/mentoring platform - Many students who are new or used to research concepts could benefit significantly from premium mentorship and training packages on research guidance, writing, and presentation.
c. A platform for collaborative research on project ideas across geographical boundaries.

1.7 Definition of Terms

Terms	Definition
Artificial Intelligence	Artificial intelligence (AI) is the capacity of a computer or robot under computer control to carry out operations typically performed by intelligent beings.
Algorithm	An algorithm is a systematic procedure that generates the response to a request or the solution to a problem in a certain number of steps.
Backend	The backend, or portion of a computer system or program, is usually in charge of storing and processing data and is not immediately accessible by the user.
Corpus	A set of machine-readable genuine texts (including transcripts of spoken data) chosen to be representative of a certain natural language or language variation.
Cosine Similarity	Cosine Similarity is a metric used to ascertain the degree of similarity between two entities regardless of their magnitude.
Data Mining	Data mining refers to the systematic extraction of patterns and useful insights from large collections of data.
Frontend	The frontend is the user interface of a software application or website that encompasses all elements that facilitate user interaction.
Natural Language Processing (NLP)	Natural Language Processing, or NLP, is the area of computer science (more specifically, the area of artificial intelligence, or AI) that tries to make machines understand spoken and written language more like people do.
Structured Query Language (SQL)	Structured Query Language, or SQL, is a standard computer language used to get data out of relational systems, organize it, control it, and change it.
Text Mining	The act of converting unstructured text into a structured format in order to find significant patterns and fresh insights.
Web Application	A web application refers to a kind of software that operates inside a web browser.
Web Framework	A web framework is a software framework specifically intended to facilitate the creation of online applications, including web services, web resources, and web APIs.

1.8 Organization of the Thesis

The Thesis organization is simple, following the sequence and procedure to put our project supervisor recommendation system into practice and assess its effectiveness.

Chapter one will give us a background into the challenge of project supervisor selection and the possible solution. The aim and specific objectives of the research in meeting the identified needs, the scope and significance of the proposed approach are elaborated here.

Chapter two will explore the existing works of literature and research that have been carried out in the field of recommendation systems in the past and their attempts at solving or proffering solutions to the challenge. Attention will be given to Cosine similarity and TF-IDF in this chapter.

Chapter three discusses the methodologies and industry best practices adopted to design the proposed framework for solving the problem associated with student supervisor selection and assignment. Both the software engineering concepts and data science concepts are discussed here, plus other relevant concepts. The flow chart and use case diagram of our approach and methodology is discussed here. Django web framework and our rationale for such a choice will also be discussed here.

Chapter four will focus on the result, analysis and evaluation of the proposed algorithm. The discussion of the results and its implications.

Chapter five will give a summary of the research work, the conclusion and recommendations for improvements and extension for more advancements.

CHAPTER 2: LITERATURE REVIEW

2.1 Preamble

This chapter briefly peeks into Machine Learning as a branch of Artificial Intelligence, Recommender Systems as a Machine Learning technique and some of the essential elements of Recommender Systems. Importantly, this chapter evaluates relevant published works on Recommender Systems and related works as it applies to student project supervisor recommendations and the summary of reviewed related works.

2.2 Theoretical Framework

This section gives a foundational review of existing theories that serve as a roadmap for developing our arguments in this research. Theoretical explanation is given to explain existing theories in Machine Learning and recommendation systems that support this research, showing its relevance and its foundation in established ideas.

2.2.1 Machine Learning

Machine Learning is the branch of Artificial Intelligence that enables computers to learn from data without being explicitly programmed. Inspired by the human learning process, Machine Learning algorithms learn from data repeatedly and allow computers to discover hidden insights (Sharifani & Amini, 2023). Machine Learning has three subcategories: Supervised, Unsupervised, and Reinforcement Learning. Supervised Learning is characterized by its use of labeled data to train algorithms for accurate prediction. Label in data is that feature used to differentiate one attribute from another. We teach the model, and then it can predict unknown or future instances with that knowledge. We teach the model by training it with data from our labeled dataset. Unsupervised Learning is Machine Learning in which the algorithm trains on the dataset and draws conclusions on the unlabeled data. It derives conclusions from the unlabeled dataset and learns from the data. Instead of controlling the model, we allow it to find information that might not be obvious to the human eye. Reinforcement Learning mimics how people learn from data daily by adapting to changes. It has a self-improving algorithm that adapts to new circumstances and learns from mistakes (Haldorai & Arulmurugan, 2019).

Machine learning has a wide range of important societal applications, including chatbots, face recognition in computer games, signing into our phones, bank loan applications etc. These all employ machine learning methods and algorithms. Common Machine Learning techniques include recommender systems, classification, clustering, association, anomaly detection, dimension reduction, etc. Although Machine Learning algorithms exist in a variety of forms, they all have robust resources at their disposal and a common framework. You may see them as pieces you can combine to create your Machine Learning model.

2.2.2 Recommender Systems as a Machine Learning Technique

One famous instance of Machine Learning is the suggestion (recommendation) systems. A Recommender engine (Recommender System) is a system that predicts what a user may want based on prior searches or purchases. Many industries, including e-commerce (eBay, Alibaba, Jumia, etc.), financial services (investments), and social media platforms (Facebook, Twitter, Youtube, Instagram, Threads and so on), engage the use of recommendation algorithms for

their products and services. Websites and services such as Netflix, Amazon, and YouTube use these algorithms to recommend videos, movies, and TV series to viewers. It is similar to how friends recommend TV series to one another based on their familiarity with show genres.

Since recommender engines have become more prevalent in recent years, there has been an increase in the number of algorithms employed in recommender systems to provide customers with individualized recommendations, improved user satisfaction and experience. Artificial Intelligence now makes recommendations of better quality than those made using traditional approaches (Zhang, Lu, & Jin, 2020). This is where Machine Learning comes in since it serves as a strong basis for developing and upgrading many of these recommender engines.

2.2.3 What are Recommender Systems?

The explosive growth of available information and rapid increase in Internet users and e-services has created an imminent difficulty of information overload, which impedes quick access to contents of interest on the Internet and frequently results in more complicated decision-making. Although information retrieval systems such as Google, Bing, Yahoo and Yandex have primarily overcome this challenge, prioritizing and personalizing information (where a system matches accessible content to a user's interests and preferences) were lacking. This development has resulted in a greater need for recommender systems than ever (Zhang, Lu, & Jin, 2020). Recommender systems are techniques and tools that make suggestions for items most likely to interest a specific user. They provide a potent way to assist users in sorting through a huge selection of items to find those that are most likely to be picked. They employ algorithms that take into consideration the user's browsing habits, searches, purchases, and preferences, among other factors. Recommender Systems help people navigate the enormous number of options available on the Internet by employing data from several sources to predict a user's preferences for items of interest. If you purchase an item from a website, other goods may be suggested depending on the content item's parameters. For instance, the algorithm may suggest different books written by the same authors or books with similar themes to the ones you recently purchased (Mohamed, Khafagy, & Ibrahim, 2019).

2.2.4 Recommender Systems Utility Matrix

The two main components of recommender systems are users and items, with each user assigning a rating (or preference value) to an item (or product). In general, implicit or explicit approaches are used to acquire user ratings. Through the user's engagement with the items, implicit user ratings are inadvertently gathered from the user. Contrarily, the user provides explicit ratings directly by selecting a value from a restricted range of point rates or indicated interval values. The rating can be expressed in a standard form (Strongly agree, agree, neither agree nor disagree, disagree, strongly disagree), numerically (five-point scale, from 1 to 5), or by a binary method (I like/do not like) or unary (information present or absent). For instance, a website may gather implicit ratings for various items based on clickstream data, user engagement metrics, and other factors. Most recommender systems employ both explicit and implicit techniques to collect user ratings. The user feedback or ratings are placed in a user-item matrix known as the utility matrix, as shown in Table 2.1. The utility matrix frequently has multiple missing values. The major challenge of recommender systems primarily concerns locating missing values in the utility matrix.

Table 2.1: Utility Matrix

	Item 1	Item 2	Item 3	Item 4
User 1	7	3	-	2
User 2	5	-	-	3
User 3	-	2	3	5
User 4	6	-	-	-

This process is frequently challenging since the initial matrix is typically sparse because consumers rate only a few items. It is also worth emphasizing that we are only interested in items with high user ratings because only such items will be recommended to users. The performance of a recommender system is highly dependent on the type of algorithm utilized and the nature of the data source, which can be textual, visual, contextual, or any combination of these (Roy & Dutta, 2022).

2.2.5 Core Element of Recommender Systems

The fundamental recommendation question is to check if a user, $u \in U$ will be interested in item $i \in I$, for U and I as the domain of users and items, respectively. The most common ways to answer such questions are:

1. To find out the set of items that u liked previously and then find the similarity between them and i.
2. To find out people who like i and try to compute their similarities with u.

In the above two cases, the similarity values are used to measure the degrees to which u is interested in i (Salau, et al., 2022). In a nutshell, recommender systems are created to determine whether an item is worth being recommended and then measure its utility. The function to define the utility of a specific item $i \in I$, to a user $u \in U$ is:

$$f : U \times I \rightarrow D.$$

The final list of recommendations, D, contains a selection of items that have been ranked based on how useful all the items are that the user has not yet consumed. User ratings are used to illustrate an item's usability. To select the best item for the user, recommender systems maximize the utility function. Utility prediction of items for a specific user changes depending on the recommendation algorithm (Zhang, Lu, & Jin, 2020).

2.2.6 Classification of Recommender Systems

Users, items (services or products that the system wishes to promote), and transactions, which reflect interactions between the system and the user, are the entities with which a recommender operates. The rating, or a user's assessment of a certain item, represents the most prevalent type of transaction. Effective Recommender Systems are distinguished from ineffective ones by their capacity to produce reliable rating projections, making this aspect crucial when assessing the methodologies (Casillo, et al., 2023). Recommender systems use several forms of Filtering

and are broadly categorized into three types: Collaborative, Content-based, and Hybrid recommender systems.

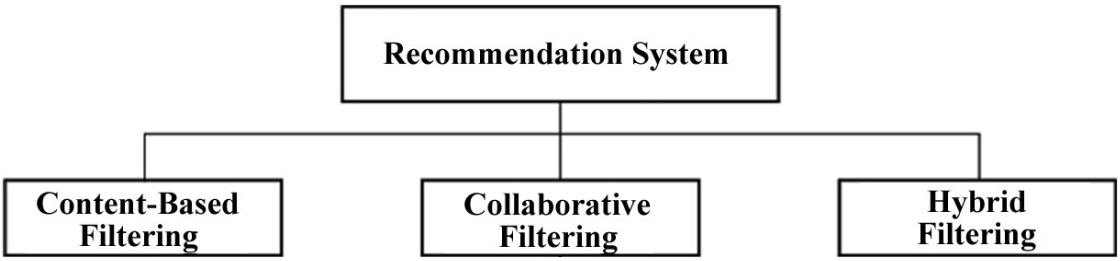

Figure 2.1: Classification of Recommendation Systems

2.2.7 Content-based Recommender Systems

Content-based recommender systems focus on suggesting items or products comparable to those that have previously ignited the user's interest. This method makes use of a certain item's attributes and metadata to propose more items with similar features.

As the name implies, content-based recommender systems predict an item's utility based on a user's profile by analyzing the item's description. To start with, several item attributes are drawn from documents or descriptions. For instance, the attributes of a movie film can be represented by its genre, director, writer, actors, plot, etc. These characteristics can be discovered directly from unstructured data, such as news or articles, or from structured data, like a table. The vector space model with term frequency-inverse document frequency weighting, a keyword-based model, is one of the most often used retrieval methods in content-based recommender systems. A user's preferences are profiled by content-based recommender systems using items from their consumption history. Typical profile information includes details on prior preferences like past likes and dislikes of the individual. As a result, the profiling process may be viewed as a conventional binary classification issue, which has been extensively researched in machine learning and data mining. In this stage, traditional techniques like Naive Bayes, closest neighbour algorithms, and decision trees are applied (Falconnet, et al., 2023). After creating the user's profile, the system analyzes the item's attributes with the profile and identifies the most suitable elements to use as the basis for a suggestion list. A content-based recommender system's recommendation process is a filtering and matching operation between the user profile and the item representation based on the features obtained in the first two phases. The recommendation's relevance evaluation is based on the correctness of the item's representation and the user's profile since the end result is to push forward the matching items and delete those the user does not like (Roy & Dutta, 2022).

There are several benefits the content-based recommender system offers, including.

1. A content-based recommendation is first user independent because it is based on item representation. Therefore, the data sparsity issue does not affect this type of system.
2. In order to address the issue of new item cold-start, content-based recommender systems can make recommendations for new products to users.
3. Content-based recommender systems can describe the recommendation outcome in detail. In comparison to other techniques, this sort of system's transparency has several advantages in practical applications.

However, there are a few drawbacks to content-based recommender systems.

1. Although overcoming the new item problem, these systems still face the new user problem since the accuracy of the recommendation result is significantly impacted by the lack of user profile information.
2. In addition, content-based techniques usually select similar items for users as recommendations, which overspecializes the suggestion. Because most users like to learn about novel and appealing items rather than being restricted to those that are comparable to those they have already used, these sorts of suggestion lists frequently lead users to get bored.
3. Another problem is that items aren't always simple to express in the precise way that content-based recommender systems demand. Therefore, rather than recommending music or pictures, this type of algorithm is more suited for promoting articles or news items (Zhang, Lu, & Jin, 2020).

2.2.8 Collaborative filtering-based recommender systems

Collaborative Filtering-based (CF) recommender systems infer the utility of an item based on other users' appraisals as opposed to content-based recommender systems, which are independent of other users but reliant on a user's personal history data. This technique got implemented in the industry world more than 20 years ago (Deschênes, 2020) and has been the subject of much academic research. Collaborative Filtering continues to be the most often utilized technique in recommender systems today (Mohamed, Khafagy, & Ibrahim, 2019). The fundamental premise of the CF approach is that people who have similar interests would seek out similar items. As a result, a system that employs Collaborative Filtering relies on data provided by users who share the same preferences as the given user.

Collaborative Filtering can be implemented using two approaches to generate recommendations based on the user's prior interactions: memory-based approach and the model-based approach. In a typical collaborative filtering situation, there exists a list of m users, denoted by U = {u1, u2, .., um}, and a list of n items, denoted by I = {i1, i2, .., in} as well as the item's opinion, also known as rating. The memory-based method predicts ratings for an active user by looking at the most similar users, whereas the model-based approach builds a model from the user/item interaction to predict ratings. The basic idea of collaborative Filtering is that collaborative Filtering make predictions based on the opinions of users with similar characteristics. Memory-based collaborative Filtering predicts using the entire user-item dataset to generate a recommendation system. It approximates users or items using statistical approaches. Pearson Correlation, Cosine Similarity, and Euclidean Distance are a few examples of these approaches. However, model-based collaborative Filtering uses the data in the database to develop a model in an attempt to learn their preferences and subsequently make predictions. Models can be created using Machine Learning techniques like regression, clustering, classification, and so (Karavidaj, 2020). Unfortunately, the scope of our research is limited to content-based recommender systems as it applies to project supervisor recommender systems.

2.2.9 Hybrid Recommender Systems

In order to enhance the system's capacity for prediction, hybrid recommender systems incorporate two or more techniques. A single model can be made to incorporate the features of the selected method or the techniques can be employed individually before being integrated (Casillo, et al., 2023).

2.2.10 The Limits of Recommender Systems

The primary issues that recommender systems face include but not limited to:

1. Scalability: the system's ability to handle additional data that is made available.
2. Sparsity (small number of known ratings) should not have an impact on the accuracy of the predictions.
3. Cold Start: The difficulties of recommender systems in predicting new users or items.

The benefits and drawbacks of the above-mentioned recommendation approaches are listed in Table 2.2 (Casillo, et al., 2023).

Table 2.2: Advantages and Limitations of Recommendation Techniques

Recommendation Techniques		Advantages	Limitations
Content-based RS		Easiness in suggesting new items Easiness of implementation	Cold Start (new user) Diversity
Collaborative Filtering RS	Memory-Based	Easiness of data updating Easiness of implementation	Cold start (new user /new item) Sparsity Scalability
	Model-Based	Compares well with sparsity and scalability The resulting performance is better	Cold start (new user /new item) Loss of information because of the use of factorization techniques
Hybrid RS		Provides better suggestions Overcomes the limitations of individual techniques	Complexity Model development cost

2.2.11 Distance Metrics in Machine Learning

The distance between two data points is used by several supervised and unsupervised machine learning models, including K-NN and K-Means, to predict the outcome. As a result, the metric we employ to calculate distances is crucial in these models. Some of the common distance metrics employed in machine learning models include the Euclidean distance, the Minkowski distance, the Manhattan distance, the Hamming distance and the Cosine distance. When determining the distance between two data points in a grid-like pattern, we utilize the Manhattan distance, sometimes referred to as city block distance or taxicab geometry. The Euclidean distance is the distance that exists in a plane of a pair of data points along a straight line. The Hamming distance is a comparison statistic for two binary data strings. The cosine distance and cosine similarity metrics are mostly used to identify similarities between two data points.

2.2.12 Cosine Similarity and Cosine Distance

The cosine similarity, or degree of similarity, reduces as the cosine distance between the data points rises, and vice versa. As a result, points that are near to one another are more similar than those that are far apart. Cos θ represents the cosine similarity, while the cosine distance is 1-Cos θ. In order to provide users with future recommendations, recommendation systems employ the cosine metric of cosine distance and cosine similarity.

For instance, if two data points are separated by 90 degrees, as in Figure 2.2 and you know that Cos 90 = 0, then you may use this to your advantage. The cosine distance between the two points is, therefore, 1 - Cos 90 = 1, which indicates that the two data points are not similar.

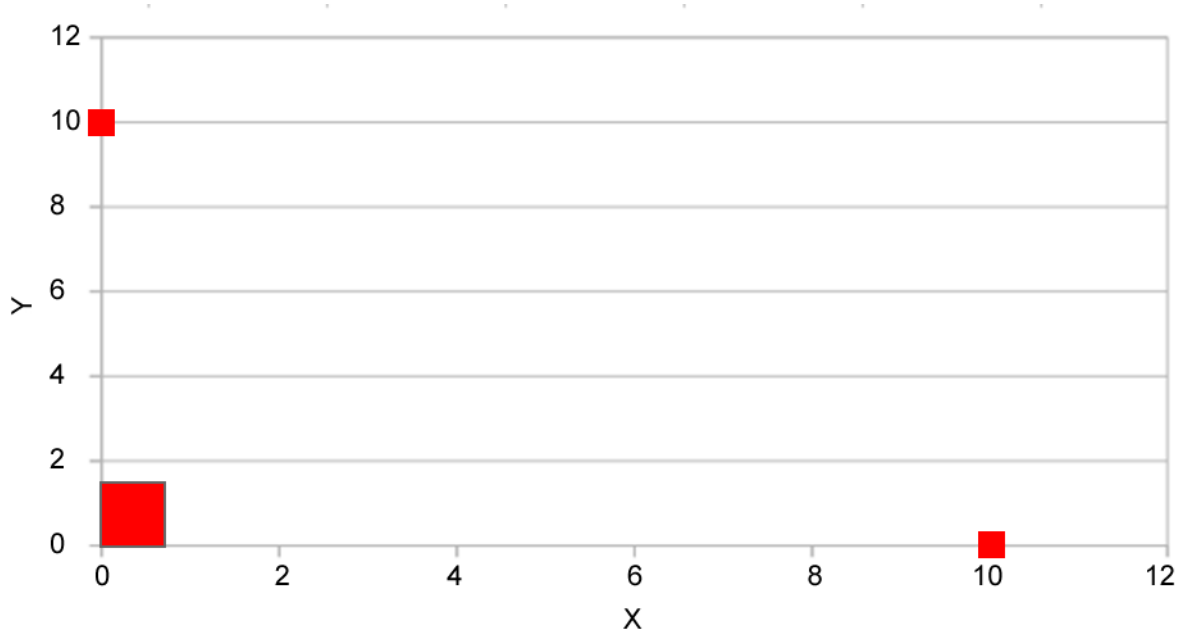

Figure 2.2: Two Data Points separated by Ninety Degrees

As seen in Figure 2.3, another example would be if the angle between the two points was 0 degrees. In this case, the cosine similarity would be 1 (Cos 0 = 1), while the cosine distance would be 1 - Cos 0 = 0. The two points are therefore interpreted to be 100% similar.

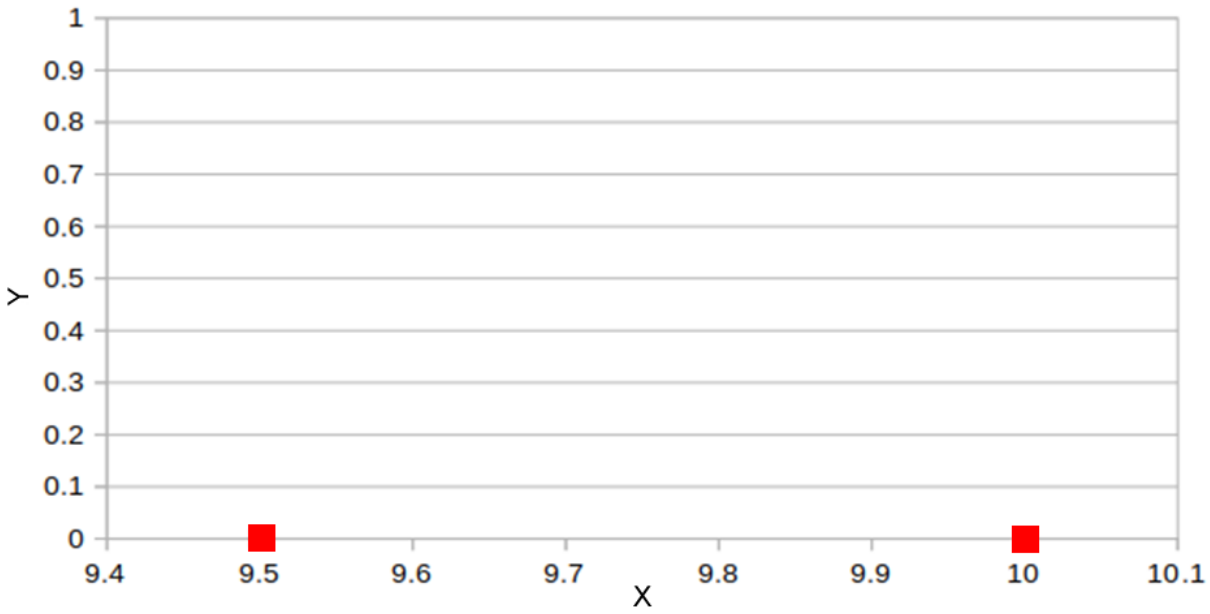

Figure 2.3: Two Data Points separated by Zero Degrees

Let's say the value of θ is 60 degrees as shown in Figure 2.4. Using the cosine similarity formula, this means that the cosine distance is 1 - 0.5 = 0.5. Consequently, there is a 50% similarity between the data points.

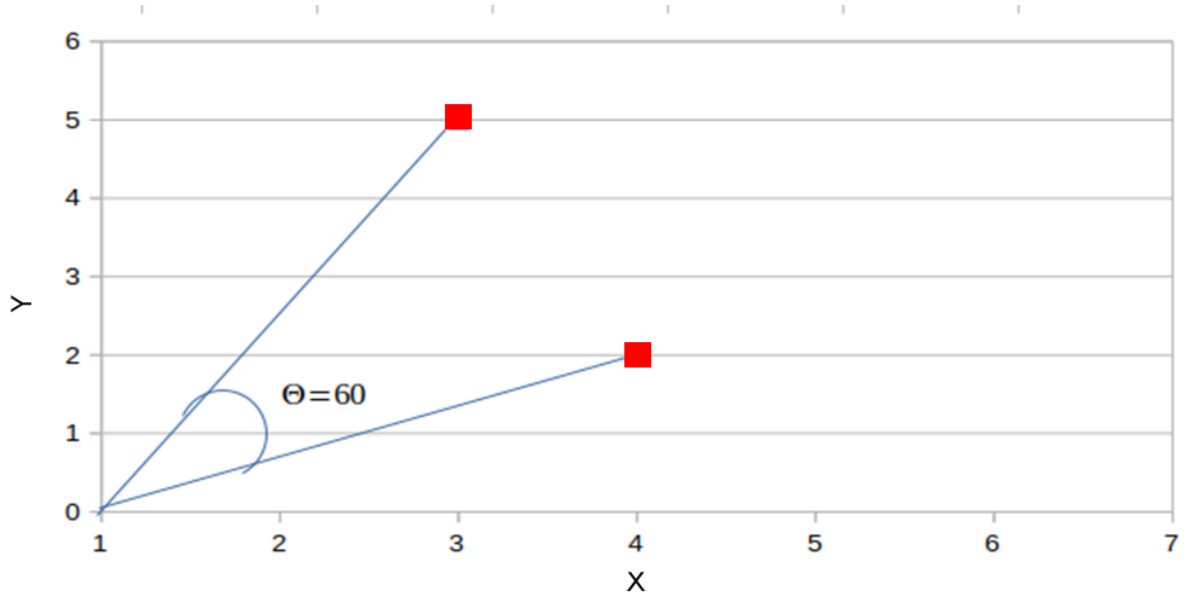

Figure 2.4: Two Data Points separated by Sixty Degrees

2.2.13 Cosine Similarity – Text Similarity Metric

In order to determine how closely two text documents are similar to one another in terms of context or meaning, text similarity is utilized. There are several text similarity measures, including Jaccard Similarity, Cosine Similarity, and Euclidean Distance. Each of these metrics has a unique specification that measures how similar two queries are to one another. In our study, the cosine similarity metric is employed. Cosine similarity is one of the metrics used in natural language processing to compare the text similarity of two documents, regardless of

their size. Vector representations of words are used. In n-dimensional vector space, text documents are represented. Cosine similarity is a mathematical metric that calculates the cosine of the angle between two n-dimensional vectors projected in a multi-dimensional environment. The-Cosine similarity between two papers will be between 0 and 1. If the Cosine similarity score is 1, it signifies that the orientation of two vectors is the same. The closer the value is to 0, the less similar the two papers are.
Cosine similarity between two non-zero vectors A and B is expressed mathematically as:

$$\text{Similarity} = \cos\theta = \frac{A \cdot B}{|A||B|} = \frac{\sum_{i=1}^{n} A_i \times B_i}{\sqrt{\sum_{i=1}^{n}(A_i)^2} \times \sqrt{\sum_{i=1}^{n}(B_i)^2}}$$

Where:
A = Vector A
B = Vector B
A • B = dot product between vector A and vector B
|A| = vector length A and |B| = vector length B
|A||B| = cross product between |A| and |B|

2.3 Review of Relevant Literature

Initially, Recommender systems were applied in e-commerce to address the information overload brought on by Web 2.0. Soon after, they rapidly expanded to personalizing e-government, e-business, e-tourism, and e-learning (Zhang, Lu, & Jin, 2020). Over the years, they have become an indispensable feature of educational and training websites, with the likes of Coursera, Udemy, etc., to recommend learning resources and online courses that might interest a specific user. Given the digitization of education and the massive increase in online learning resources via massive open online courses and learning management systems, recommender systems research has been advancing rapidly. These systems today are being used in a growing number of specialized fields, notably in the domain of Technology-enhanced Learning (TEL) (Deschênes, 2020).

Recent literature evaluations on recommender systems in education have taken into account quite a number of methodologies and approaches. In one of such literature, ontology-based recommenders were examined. The research was carried out in 2018 by Tarus, Niu, and Mustafa, where they acknowledged that ontology-based recommendations paired with other recommendation techniques are frequently used to suggest learning resources, but they didn't thoroughly investigate techniques that may be combined with this recommendation (Tarus, Niu, & Mustafa, 2018).

Ontology is a method of modeling learners and learning materials, among other things, to aid in the retrieval of details. This results in more relevant content for learners. Ontologies provide the advantages of reusability, reasoning ability, and support for inference procedures, which aid in providing better recommendations (George & Lal, 2019).
Another study by Charbel Obeid, Inaya Lahoud, Hicham El Khoury, and Pierre-Antoine Champin on ontology-based recommender systems in higher education reveals a method for creating ontology-based recommender systems improved with machine learning techniques to guide students in higher education. The recommender system serves as a tool for evaluating

students' interests, skills, and areas of occupational strength and weakness (Obeid, Lahoud, Khoury, & Champin, 2018).

Despite all the benefits that ontology offers, the names given to the ontology model's different classes, properties, and individuals are a challenge. Another issue while developing ontologies is the inappropriate usage of classes and persons (George & Lal, 2019).

A unique Learning Companion Application with adaptive learning technologies that optimize Technology Enhanced Learning (TEL) offerings to match the individual learner's needs was presented in research titled Time-Dependent Recommender Systems for the Prediction of Appropriate Learning Objects (Krauß, 2018). The application provides learning recommendations to help you choose more efficient and effective content. It was determined that standard recommender systems could not be easily transferred to TEL because course item recommendations followed a specific educational paradigm. The unique characteristics of this paradigm are first examined and then considered while developing new algorithms. A reference architecture for such an adaptive learning environment is created by a collection of open standards and specifications, allowing for extensive compatibility of a Recommender System with other technical elements. Based on the realized architecture, activity data were collected from students via online course materials - the courses include face-to-face lectures supplemented by digital representations of the delivered contents, blended learning environments, and online-only courses. This research also suggests that an educational recommender system should not be examined using typical evaluation frameworks such as n-fold cross-validation. As a result, a time-dependent assessment framework is defined to examine the precision of Top-N learning suggestions at different periods.

2.4 Review of Related Works

The application of computational methods to analyze document similarity in specialized industry domains has been a research subject over the years with practical applications in different industries, including legal, academic, news publishing, search engines, etc. However, innovations in Text Mining (TM) and Natural Language Processing (NLP) in the second half of the 2010s, such as Text Embeddings based on Neural Networks (NNs), gave this area new possibilities and a boost (Silva et al., 2022). The document format or representation, the text embedding (also known as text vectorization), and the similarity measurement technique are the three primary parts that are often varied when investigating textual similarity. Typically, the similarity measurement technique makes use of a vector distance metric (Hugo Mentzingen et al., 2023).

In the white paper, A Survey of Numerous Text Similarity Approach Dasgupta (2023), several approaches focusing on various text similarity techniques used in everyday life use cases to calculate the similarity between contents were surveyed. Among them are Euclidean distance, cosine similarity, Jaccard Distance, Manhattan distance etc. It was pointed out that methods for resolving text similarity use cases have been available for a while, but their key shortcomings include the loss of dependence information, the inability to recall lengthy conversations, inflating gradient issues, etc. Modern deep learning models pay attention to both nearby and far-off words, which improves their capacity for rigorous learning (Dasgupta et al., 2023).

The findings of using several strategies for semantic text similarity measures in documents used for safety-critical systems are presented by Qurashi (2020) in Methods for Semantic Text Similarity Analysis. It was discovered that documents with unstructured data and different formats needed to be preprocessed and cleaned before the set of Natural Language Processing toolkits, and Jaccard and Cosine similarity metrics were applied. The research aimed to measure the degree of semantic equivalence of multi-word sentences for rules and procedures contained in some documents. The outcomes show that by utilizing Natural Language Processing and similarity measurement approaches, it is possible to automate the process of finding identical rules and procedures and gauge the similarity of various safety-critical documents (Qurashi et al., 2020).

Several studies have been conducted on recommender systems as regards final year projects, the graduating students, in some cases predicting project topics, some recommending lecturers, research materials, acting as repositories, etc.

In their research, Arumi (2019) developed an Analytical Hierarchy Process (AHP)-based decision support system for selecting thesis supervisors. It takes into account the lecturer's area of expertise in accordance with the criteria for selecting lecturers, lectured subjects, conformity of thesis title topics, and duration of guidance. Data is extracted from Google Scholar, the decision letter for each semester's instruction, and the submission of student thesis proposals. The weighing of the criteria according to the AHP method shows that the title of the proposed thesis is the factor that has the most impact on the selection of the lecturer as thesis supervisor, followed by the lecturer's research interests and the lecture they delivered, according to the eigenvector value's outcome (Arumi et al., 2019).

Fiarni et al. (2021) use a Machine Learning technique to study and construct an algorithm that recommends final project topics based on a student's interests, skills, and assigned supervisor. As a feature selection component, this research also built a framework to map academic qualities. In order to recommend topics based on similarities between student profiles and those topics represented by lists of keywords, a recommender system based on the cosine similarity algorithm was created. Performance is assessed by contrasting the recommended system's suggestions with the actual topic selected by the students, with a high accuracy score of 71.43% (Fiarni et al., 2021).

In another research, Kazakovtsev (2020) developed a recommender system for selecting an academic supervisor based on evaluating the similarity of student interests and the scientific accomplishments of the potential mentor from the university faculty. The recommender system used an unconventional method to calculate similarity without using co-authorship networks instead of Scopus quality metrics. The cumulative distribution function of the logarithm of the weighted impacts of academics in the field was applied as a normalizing technique. Due to the difficulties of comparing the received recommendations with the data from previous years, it evaluated several similarity measures. After that, clustering was performed to assess their suitability and the system's quality (Kazakovtsev et al.).

A web-based system using the TF-IDF word weighting and cosine similarity algorithm was developed by Rismanto et al. (2020) in the research, Research Supervisor Recommendation System Based on Topic Conformity. With the TF-IDF approach, one could determine the importance of a word's connection to the document. Using keywords from a document as a measure, the cosine similarity is used to determine how similar two items expressed in two vectors are to one another. The final assignment adviser who has done a study on the subject of the student's final assignment is recommended to students based on the findings of the advisor recommendation system. By comparing system suggestions with the real assigned supervisor in 20 tests, the accuracy of comparing the outcomes with the actual data averaged 75% (Rismanto et al.).

Wijanto (2020) creates a thesis supervisor recommender system with representational content and retrieval of information. When a student thesis proposal is accepted, the system responds with a list of potential supervisors in decreasing order based on the relevance of the prospective supervisor's academic publications to the proposal. Similarly, the profiles of supervisors are drawn from previous scholarly papers. The research employs the information retrieval idea with cosine similarity and a vector space model for scalability. Findings show that grouping supervisor candidates based on their broad experience is beneficial in matching a possible supervisor with a student, according to the accuracy and Mean Average Precision (MAP). Lowercasing has been shown to improve accuracy. The MAP benefits from considering the top ten most common words in each lecturer's profile. (Wijanto et al.).

Madeira (2021) analyzes a recommender system that enables one to select an academic supervisor based on their academic genealogy in their research utilizing the Nearest Centroid model. Application of metadata from several theses and dissertations was used to carry out the recommendation. The acquired findings demonstrated a high degree of suggestion precision, supporting the claim made by Madeira et al. that the suggested approach is a helpful tool for graduate students.

In his research article, Hasan (2019) employed the K-Nearest Neighbour method with cosine similarity to locate supervisors based on individual preferences. The collaborative filtering algorithm was employed by the recommender system. According to the user's choices or areas of interest in the research, it uses multiple filtering factors to identify relevant supervisors. The model (Hasan) attained a classification accuracy of 76.0% for the expected outcomes.

2.5 Summary of Reviewed Related Works

The review of these related academic works in the preceding section 2.4 shows that significant research and advances have been made in the past, yielding knowledge that one can build on to create a unique research supervisor Recommender System. This research showcases an effective way of matching a potential supervisor with a research student using text vectorizations, cosine similarity method and displaying the top-recommended result on a web-based interface. It intends to fill the automation gap in the supervisor selection process with high-accuracy recommendations and complement the decision support system.

CHAPTER 3: RESEARCH METHODOLOGY

3.1 Preamble

Research methodology is an essential consideration before beginning a research endeavour, as it outlines the specific phases of structured/systematic procedures or techniques used to identify, select, process, and analyze information about the topic of discussion. The research methodology utilized in this study is depicted in Figure 3.1.

3.2 Problem Formulation

This phase involves the identification and conceptualization of the problem based on research findings. After recognizing the challenges related to the inefficiency of the manual project supervisor selection process, which hampers productivity and motivation among students and their supervisors, it is crucial to explore potential solutions and define the scope of the problem for further investigation.

3.3 Proposed Solution, Technique, Model/Framework

In this research, the Cross-Industry Standard Process for Data Mining (CRISP-DM) is used, which is a common practice in data mining tasks, as is often seen in the field of Machine Learning research. The CRISP-DM framework is a well-established and universally applicable standard for efficiently structuring data mining projects.

Figure 3.1: Cross-Industry Standard Process for Data Mining (CRISP-DM)

The paradigm in question has been widely used in several industrial projects and has consistently shown its efficacy in practical implementation. (Schröer, Kruse, & Gómez, 2021)

The process has six iterative steps, beginning with business understanding to deployment of the solution.

The process of CRISP-DM is classified into:

1. Business Understanding
2. Data Understanding
3. Data Preparation
4. Modeling
5. Evaluation
6. Deployment

Table 3.1 provides a concise overview of the primary concept, activities, and outcomes associated with each phase.

Table 3.1: CRISP-DM Process Model Descriptions

S/N	Phase	Short Description
1	Business Understanding	The business or project situation is evaluated to determine the available and necessary resources. Determining the data mining objective is one of the most crucial aspects of this phase. The data mining type (e.g., classification, clustering, association) and performance criteria (e.g., precision) is explained first. This phase is mandatory and foundational because it forms the premise for the project plan.
2	Data understanding	In this phase, collecting data from data sources, investigating and describing it, and assessing its quality are essential duties. To make it more tangible, statistical analysis are performed; their attributes and their collations are determined in order to describe the data. Tableau and Excel comes in handy here as among the tools being utilized for data understanding, so it makes ideal sense to import the data into these programs. If you acquire multiple data sources, you must consider how and when these will be integrated.
3	Data preparation	The process of data selection involves the establishment of specific criteria for inclusion and exclusion. The issue of poor data quality may be effectively addressed via the process of data cleansing. The construction of derived characteristics is contingent upon the model used, as established in the first step. Various approaches may be used for each of these processes, and the choice of method is contingent upon the specific model being used.
4	Modeling	The data modelling step include the process of choosing the appropriate modelling approach or technique, constructing the test case, and developing the model. Various data mining approaches may be used. The selection often hinges upon the specific business issue at hand and the available data. Of more significance is the elucidation of the rationale behind the selection. In order to construct the model, it is necessary to establish specified parameters. In order to analyze the model, it is advisable to test it against predetermined assessment criteria and thereafter choose the most suitable ones.
5	Evaluation	During the evaluation phase, the obtained outcomes are compared and assessed in relation to the predetermined business or project goals. Consequently, it is necessary to analyze the findings and establish further courses of action. Another aspect to consider is the need for a comprehensive evaluation of the process.
6	Deployment	The deliverable in question has the potential to take the form of either a comprehensive report or a software module. The deployment phase includes the activities of deployment planning, monitoring, maintenance and final report.

There is no restriction on how the CRISP-DM may operate; it can alternate between many stages. The outer circle denotes the framework's cyclic qualities, and the arrows indicate that the requirements between phases are crucial to each other. CRISP-DM, as the outer circle graphic illustrates, is not a one-time procedure in and of itself. Every procedure is a fresh opportunity for learning, and it may raise more business issues as well as teach us new things.

Reduced costs and time are two advantages of adopting standard process models for data mining, such as the de facto and most widely used Cross-Industry-Standard-Process model for Data Mining (CRISP-DM). Standard models also reduce the amount of information needed and help with knowledge transfer and best practice reuse. (Ayele, 2020)

3.4 Tools Used in the Implementation

A variety of tools and techniques were utilized during the research's implementation, and they are detailed in the sections that follow.

3.4.1 Functional and Non-functional Requirements

Functional and non-functional requirements are essential for a product to fulfil the requirements of stakeholders and the business. However, it is evident from the name that they prioritize distinct aspects.

3.4.1.1 Functional Requirement

Features and functionalities of the application are defined by the functional requirements. Some of the essential functional requirements of the project supervisor recommender system include:

1. The system should be able to display project supervisor recommendations
2. The system should be able to display information regarding lecturer(s).
3. The system should be able to display information regarding a lecturer's previous research submissions.
4. The system should be able to execute the cosine similarity method for calculating document similarity.
5. The system should be able to accept input from users to search against lecturers' research dataset
6. The system should be able to get input from the Admin to record lecturers' details and their past publications into the database.

3.4.1.1 Non-functional Requirements

1. Speed
2. Security
3. Reliability
4. Data Integrity
5. Usability

3.4.2 Resource Requirements

Resources used in this Research are categorized into the following: Data, Cloud, Hardware, and Software.

3.4.2.1 Data Resources

The main subject of this research work is data (research data). It also acts as the foundation for the analytics and visualizations of this project. A representative dataset of eighteen lecturers'

publications is used to investigate combinations resulting from one thousand one hundred and thirty-seven (1,137) publication representations, which were extracted online from lecturers' Google Scholar publications and saved as spreadsheets. For accessible data collection, cleaning and manipulation, the spreadsheet was also synced in the cloud.

3.4.2.2 Cloud Resources

Machine learning experiments typically commence by conducting data analysis on a computer, often without requiring substantial computational resources. Over time, individuals may increasingly require additional resources beyond what their local CPU can provide, which is made possible by the advent of cloud computing. The data collection process involved synchronizing data in the cloud using Google Sheets for the purpose of conducting experiments. Furthermore, using cloud architecture for certain machine learning pipeline activities during the model-building process was aimed at enhancing accuracy. This approach allows access to a centralized resource, enabling the utilization of a developed system. Tableau is a cloud-based service utilized for data analytics in this research. Tableau has the potential to enhance our ability to explore, manage, and derive insights at a faster pace.

3.4.2.3 Minimum Hardware Requirements

The minimum hardware requirements refer to the computer's physical features required to implement the Recommendation System. The features are as follows:

1. Processor: at least Intel Pentium Dual-Core
2. Memory: 4 GB RAM
3. Disk space: 250 GB HDD

3.4.2.4 Software

1. Python 3.10
2. Django Web Framework
3. Visual Studio Code
4. PIP
5. Included Library packages: NumPy, SciPy, Scikitlearn, Pandas, Matplotlib
6. Windows 10 Operating system, MAC.
7. Chrome, Edge and Mozilla Firefox browser

3.5 Approach and Technique(s) for the Proposed Solution

All system components and process flow are explained in the architectural diagram. It overviews the process and helps distribute modules to the group. The architectural diagram shows its organization. Process behaviour may be predicted from the developer's architectural diagram. This section briefly describes our proposed system's modules. (Muthurasu, Rengaraj, & Mohan, 2019)

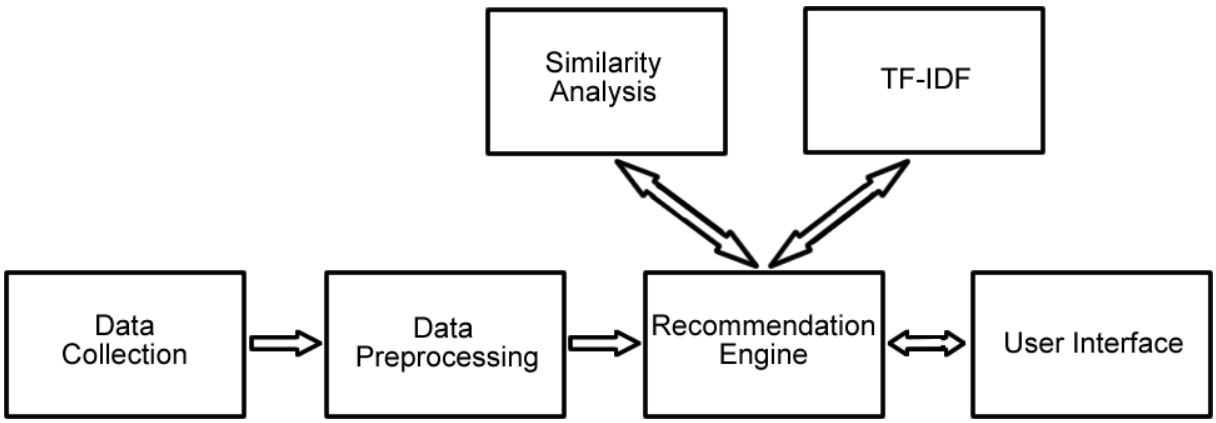

Figure 3.2: Architecture Diagram

3.5.1 Data Collection

Data collection refers to the systematic process of gathering data that is relevant to our specific requirements. The data required for our project's Supervisor recommendation system is textual data. The first dataset contains brief bios of ACETEL's MIS Department lecturers. The data is presented in a spreadsheet format. Table 3.1 shows the Supervisors bio data attributes.

Table 3.2: Supervisors Bio Data Attributes

Number	Attributes	Information
1	Name	Supervisor's Name
2	Gender	Supervisor's Gender
3	Email	Supervisor's Email
4	Phone	Supervisor's Phone

The second dataset consists of the research publications of the same ACETEL lecturers stated in the first dataset. This data was obtained by sourcing and web-scraping information from each lecturer/facilitator's Google Scholar profiles. The data attributes include each publication's author name, title, abstract, and keywords. The necessary data was extracted for each lecturer by parsing web pages in HTML format and extracting data from PDF documents. The data was inputted in the form of a CSV file and subsequently parsed during the data processing phase. A total of one thousand one hundred and thirty-seven (1,137) rows of data were extracted, each containing the attributes listed in Table 3.2.

Table 3.3: Supervisors publication data attributes

supervisors_publications

Figure 3.3: Cropped section of Supervisors' publications dataset in a spreadsheet

3.5.2 Data Preprocessing

The first stages in every recommendation system start with data preprocessing.

Due to an unintentional inclusion of HTML, the retrieved supervisors' publications data remained in their unprocessed state. There were both alphabetic and numeric characters, as well as blank rows. Thus, the raw data was subjected to data preprocessing in order to enhance the data format and remove interference, data inconsistencies, and noise.

The following are examples of the data preparation procedures that were carried out.

1. Tokenization
2. Case folding
3. Punctuation removal
4. Stop word removal
5. Word vectorization

Prior to using the data as a vector for proximity and similarity measurement, it was necessary to perform noise removal. In addition, the data have to go through the process of tokenization. The data, which is presented in lengthy phrases, will be segmented into individual words or tokens. Subsequently, after the data has been transformed into a token, it will undergo case folding and punctuation removal, followed by the application of the stopword procedure. Commonly occurring terms in the dataset, which are included in the stoplist, must be eliminated. Stoplists are compilations of words, also referred to as stopwords, that are excluded from being indexed in an information retrieval system and/or are not permitted for use as query terms. Stoplists may be categorized as either general or domain-specific, and it is important to note that they are peculiar to a particular language. As an example, the terms "and," "are," "as," "but," "by," "for," "if," "in," and so on. (kalaivani & Marivendan, 2021)

Once the data has undergone the procedures leading to its transformation into a token, the subsequent stage involves the conversion of the data into a vector. This conversion is achieved by the use of the TF-IDF approach, using an n-gram range spanning from one to two words. An n-gram refers to a consecutive sequence of n elements extracted from a given text, often

used in the fields of linguistics and computational probability. The use of N-grams enables the estimation of the likelihood of the subsequent word, hence facilitating comprehension of the semantic context within a given text. The fundamental principle of this approach is the computation of TF and IDF values for each term in relation to every document. (Falah & Suryawan, 2022)
It is essential to carry out this procedure to get clean data before its utilization in the recommendation algorithm.

3.5.3 Data Processing (Recommendation Engine)

In this study, the similarity between the lecturer's research and the proposal provided by students is calculated by comparing the title, abstract, and keywords of potential supervisors' research with those of the student-submitted proposals. Two important techniques will be discussed here to help us achieve the recommendation goal. They include TF-IDF and Cosine Similarity.

3.5.3.1 TF-IDF (Term Frequency-Inverse Document Frequency)

The TF-IDF (term frequency-inverse document frequency) is a statistical metric used to assess the significance of a word inside a given text in a set of documents. This process is achieved by multiplying two metrics: the term frequency, which measures the number of occurrences of a word inside a specific document, and the inverse document frequency, which quantifies the rarity of the phrase over a collection of documents. (Jiang, et al., 2021) The technology has several applications, with particular significance in the realm of automated text analysis. It proves very advantageous in evaluating word scores inside machine learning algorithms used in the Natural Language Processing (NLP) field.

The TF-IDF approach is a widely used technique in the field of information retrieval for determining the significance of individual words by assigning weights to them. The TF-IDF technique was used to identify the most significant terms in the title and abstract of the student's study. These words will be afterwards compared to a database of potential research titles and abstracts using the cosine similarity approach.

The process of word weighting plays a significant role in determining the level of similarity between a document and a query. The weight calculation method presented here combines two key concepts: the frequency of occurrence of a word within a specific document and the inverse frequency of the document containing the word. Several factors are crucial in determining word weighting. These include:

1. **Term Frequency (TF)**
   Term Frequency (TF) refers to a numerical representation that indicates the frequency of a term within a given document or corpus. It is a key metric used in natural language processing and information retrieval tasks. TF is calculated by dividing
   Term frequency (TF) refers to the numerical representation of the occurrence of words or terms within a given collection of documents. There are several types of Term Frequency (TF) measures, including Raw TF, Logarithmic TF, Binary TF, and Augmented TF.

2. **The Concept of Inverse Document Frequency (IDF)**

The IDF (Inverse Document Frequency) values are calculated for every token (word) in each document within the corpus.

The calculation of IDF is performed using the following formula:

$$idf = \log \frac{D}{df}$$

Where:

idf = Inverse document frequency

D = Total Documents

df = Frequency of documents from term

log = To minimize the effect relative to tf

W = $t\ f\ x\ i\ df$

The term weight is calculated using the formula

Where:

W = Weight of document

tf = Frequency term

idf = Inverse document frequency

3.5.3.2 Cosine Similarity Method

The following equation can be utilized to determine the value of cosine similarity between vectors.

$$im\ (q, d_j) = \frac{q, d_j}{|q|x|d_j|} = \frac{\sum_{i=1}^{t} w_{iq} x\ w_{ij}}{\sqrt{\sum_{i=1}^{t}(w_{iq})^{\ 2}}\ x\ \sqrt{\sum_{i=1}^{t}(w_{ij})^{\ 2}}}$$

Where:

q = Vector query, which will be compared for similarity

d = Vector document j, which will be compared for similarity

| q | = Length of the query vector

| d | = Document vector length j

Wiq = Weight of the word i in the query q

Wij = Weight of the word i in document j

The recommendations produced by the engine are presented to the user via a user interface.

3.5.4 Web-based User Interface

A web-based user interface is designed to serve as an intermediary between the recommendation algorithm and the user. The user utilizes this interface to submit query data, which is then used to search and get the possible project supervisor that closely matches the user's requirements. The integration of the recommendation algorithm is included in the web-based application. The web-based component of the recommendation system is written in Python programming language, and the interface is developed using Django, a web framework written in Python. Because of the Django Web Framework's great and robust features and its inbuilt tools for web development, Django is utilized as the web system's back-end, which is

responsible for providing the user with requested data. Python was used to script the backend, whilst HTML, JavaScript, and CSS were utilized for managing HTTP requests, forming the front end of web development.
The design of frontend web pages prioritizes user-friendliness and alignment with actual scenarios, therefore avoiding the need for users to manually input codes or instructions. The project resource data in the database will be accessed by the system user using the web interface.

Figure 3.4 illustrates the fundamental aspects of the web application process, including the frontend and backend components.

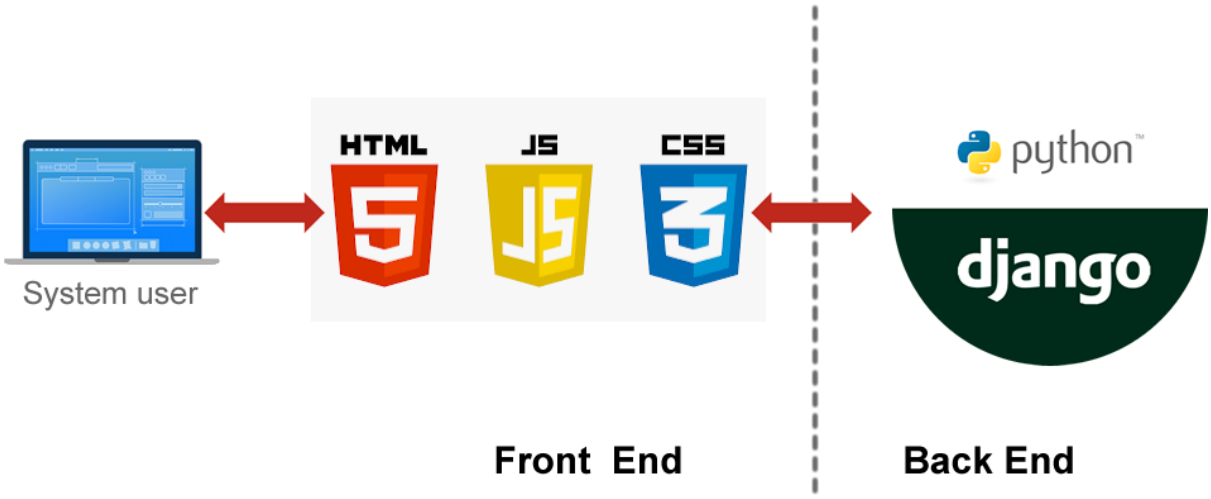

Figure 3.4: General Basics of the Website Process

3.5.4.1 What is Django?

Django is a Python-based framework for creating web applications. The Framework offers a set of regulations, frameworks, and capabilities that enable the utilization of Python code and libraries on the backend of our web application. Python is the programming language that is used for the purpose of working with Django. Subsequently, Django has the capability to engage with our web applications in order to transmit data to the end user of such web application.

3.5.4.2 Why Use Django?

In our bid to realizing the functional and non-functional requirements of our recommendation system, which combines elements of Machine Learning and Software Engineering, we chose Django as our choice web application development framework. This decision is based on the following rationales for Django:

1. It enables fast development
2. Numerous common features are included.
3. It is regularly updated and has robust security measures.
4. The scalability of the system is really pronounced.
5. It is very versatile with Python and adaptable in using the Python programming language.

6. Django is renowned for its comprehensive built-in Python modules that take care of common web application features. Some of Django's built-in functionalities include:

    - Administration
    - Authentication
    - Database Interaction
    - Security

7. Since it uses Python as its programming language, Django enables seamless access to a wide array of Python libraries.
8. Our Machine Learning-enabled recommender system makes use of algorithms built with Python programming language. By using Python and its associated tools, we are able to seamlessly incorporate the system into our codebase, leveraging the capabilities provided by the Django framework.
9. The use of this Django technology facilitates the extension of Python-based projects into interactive web-based applications.
10. Interestingly, some of the most robust popular web applications use Django, including Instagram, Spotify, YouTube, Pinterest, Dropbox, Eventbrite, etc. This indirectly implies that if Django is good enough for these top tech companies, then it should be suitable for our application too.

From the Django point of view, the general basic website process described in Figure 3.4 can be x-rayed to better comprehension as revealed in Figure 3.5.

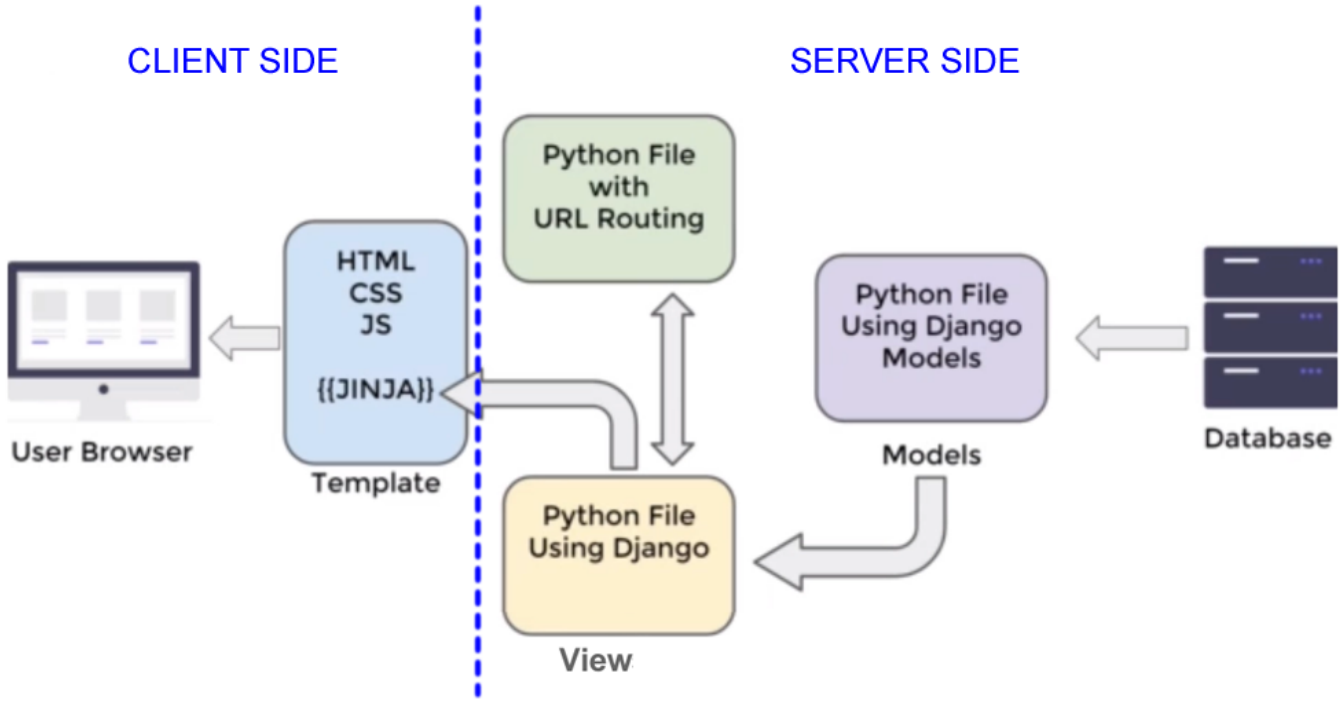

Figure 3.5: How Django Works: Communication between User and database in Django web Framework

3.5.4.3 Key Features of Django

Django is centred around the **Model-Template-View (MTV)** structure. Django factors what a typical user would do around web-based applications, which include collecting information from the database all the way to the user browser, analyzing the data, updating and saving it back to the database. These all happen around the MTV structure. The term Model in MTV is a Django concept for interacting with databases.

Figure 3.6 shows a Model Template View (MTV) Architecture of Django Framework with the sectionalized components to give a descriptive view.

Template: The use of {{JINJA}} enables the direct insertion of information from a Python file into a template, such as HTML, CSS, or JS.

Views: The Views component, views.py, is a Python file containing a collection of functions that enable the injection information into the template. This feature enables the use of several libraries, facilitating data processing and the seamless integration of information into the template in a format compatible with the user's web browser. The View component operates in conjunction with URL routings defined in the URLs.py file, which is an additional Python script that specifies the mapping between views and corresponding URL routes. The view is often linked to a model.

Models: Models are a specific component inside the Django framework, serving as a representation of a database and its corresponding table. The models.py file is often referred to as another Python file in the context of programming. When using Models in Django, users are relieved from the burden of directly handling SQL queries and managing the underlying database operations.

Models provide a means of interacting with a database using the Python programming language and the Django web framework. This encompasses the fundamental interactions with a database, often referred to as CRUD: Create, Read, Update, Delete.
Databases allow us to use information we can store on our website. The Django Model is the component that interacts with our database. The database used in this research is an SQL-based database as opposed to a NoSQL database. SQL databases are tabular, similar to a spreadsheet like Excel, while NoSQL stores data in key/value pair format. There are lots of SQL databases, including MySQL, SQLite, PostgreSQL, MS SQL and lots more. Django integrates seamlessly with most SQL engines, making switching to another SQL engine easy with few updates of the settings.py rather than rewriting Python Django code. SQLite is used in this research work as it comes already installed with Python.

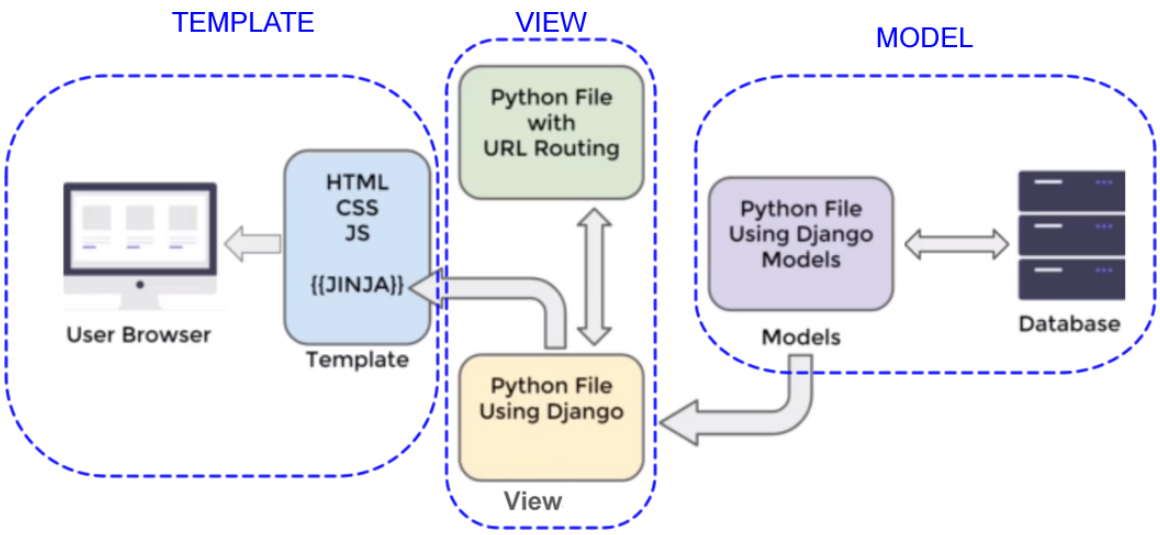

Figure 3.6: Model Template View (MTV) Architecture of Django Framework

Since our recommendation system is highly reliant on data interaction between the models and the database, with lots of connectivity, the aspect of the Django framework that handles data analysis, Machine Learning and the like is the application logic. Figure 3.7 shows the Django Framework Expanded View including the Application Logic (Machine Learning) component.

You can also have many more Python files or application logic. e.g., App.py and you just connect them through import connecting to the Python Views.py file and Models back and forth or even Models directly to the View or whether you're using some application logic.

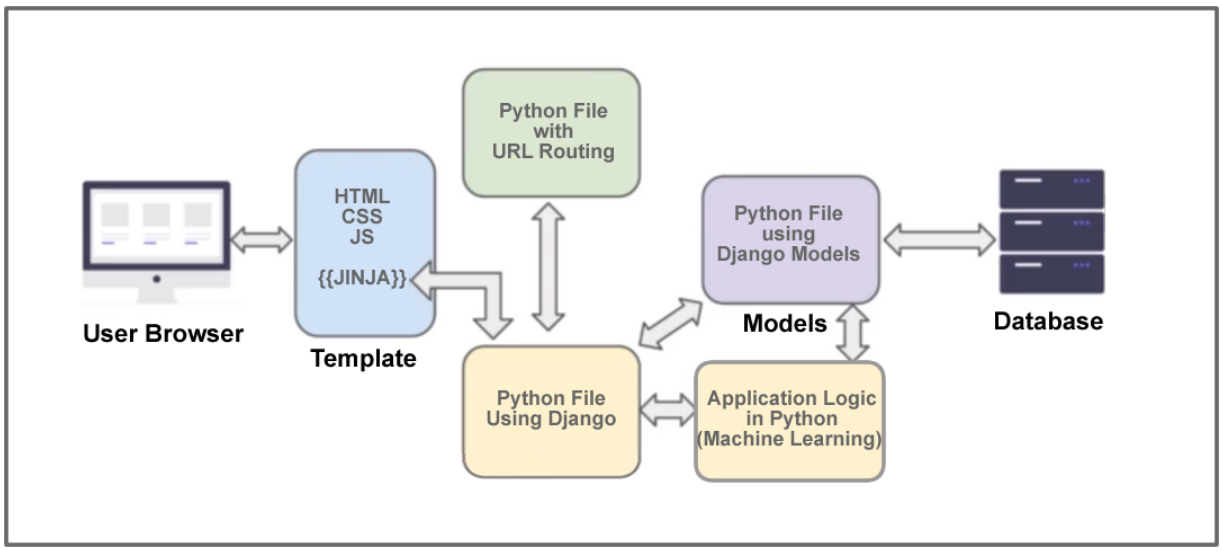

Figure 3.7: Django Framework Expanded View including Application Logic (Machine Learning) component

3.6 Research Design

In this stage, going by the functional requirements and the ultimate goal of the project supervisor recommender system, a number of designs are needed to illustrate the interactions between various systems, users and stakeholders. This includes the Use Case diagram (See Figure 3.8) and implementation flowchart (See Figure 3.9).

3.6.1 Use Case Diagram

A Use Case Diagram is a visual representation that illustrates the potential interactions between a user and a system. Figure 3.8 displays the Use case diagram for our recommender system. The Unified Modeling Language (UML) employs diagrams to provide a concise representation of the system's users, also referred to as actors, and their interactions with the system. The Figure displays the use case diagram, which effectively illustrates the system scenarios, system goals, and scope.

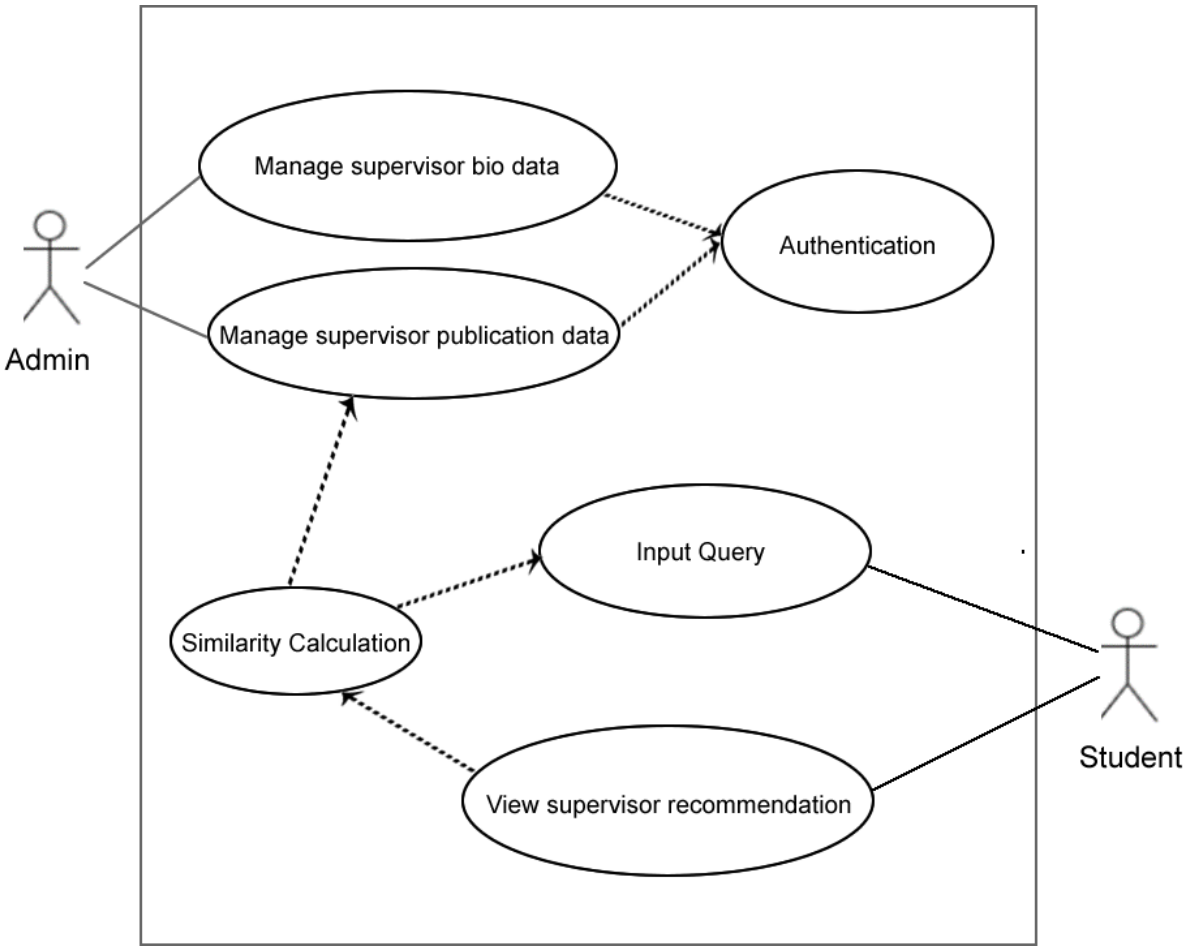

Figure 3.8: Project Supervisor Recommendation System Use Case Diagram

The supervisor's recommendation system consists of two actors: the admin and the students. The initial actor in this context is the administrator, as depicted in the accompanying illustration. The administrator possesses the capability to oversee lecturer data, including tasks such as inputting new lecturer data, deleting existing lecturer data, and modifying lecturer data. The administrator has the ability to manage both the lecturer data and the lecturer research data once logged in. The second actor is identified as a student. Students are not required to log in to access the system. However, they are able to view data pertaining to lecturers and previously published research publications. The research proposal requires students to input the title, abstract, and keywords. Once the student has entered these details, they will be able to view and identify the lecturer who is aligned with their research topic. The displayed data consists of the names of the lecturers that closely match the research proposal, arranged in descending order based on hierarchy.

3.6.2 Implementation Flowchart

The primary objective of the recommendation system is to aid students or the institution as the case may be in identifying appropriate research project supervisors by utilizing the information they provide. Figure 3.9 presents a comprehensive depiction of the flowchart for the system implementation.

The system is implemented using the Python programming language in conjunction with the Django framework. The database utilized in this system is MySQL. The implementation of the system involves the utilization of a web-based application interface for the recommender system. The task at hand involves the creation of a database and subsequent data entry. The required data includes information pertaining to lecturers, such as their personal details, as well as data related to their past research publications. The cosine similarity method is utilized to calculate document similarity in various applications.

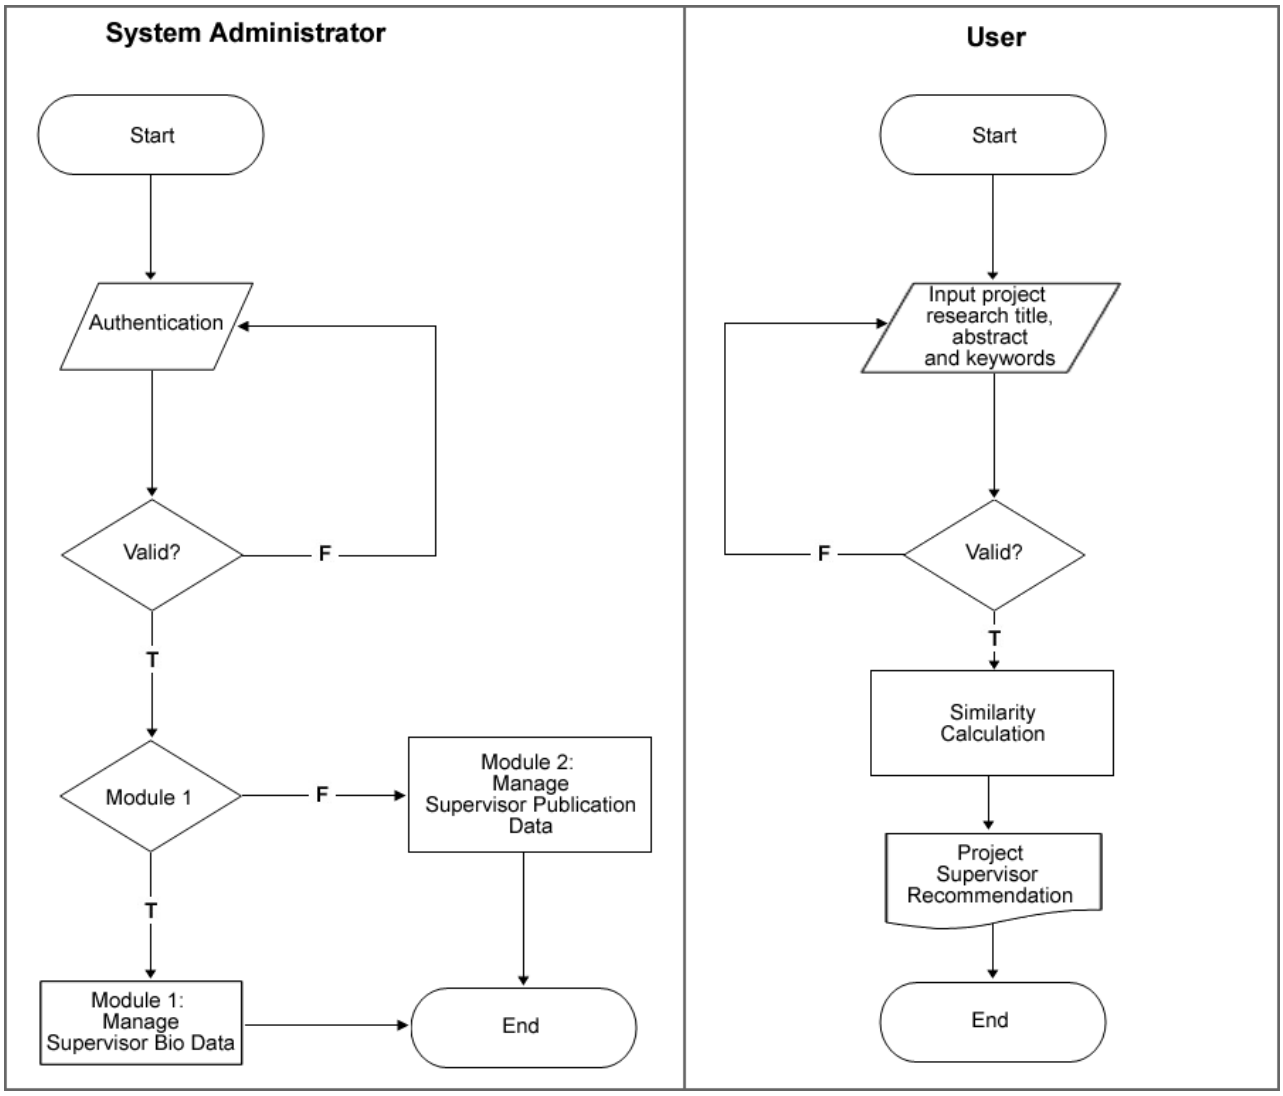

Figure 3.9: Project Supervisor Recommendation System Process Flowchart

CHAPTER 4: RESULT AND DISCUSSION

4.1 Preamble

Preceding chapters and discussions took us through various sections stating in clear terms the research aim, scope, and background. Relevant works of literature buttressing our undertakings and solidifying our strategies in employing the right methodology were also looked into extensively. The major goal here is to analyze the performance and efficacy of the supervisor recommendation system in the context of Machine Learning and Natural Language Processing tasks implemented within the Django web framework.

We want to see how effectively the system can use student inputs and a content-based filtering approach of recommendation system using a cosine similarity matrix and algorithms to identify and suggest appropriate project supervisors based on close proximity between students' project proposal query and past research publications of potential supervisors.

4.2 System Evaluation

Following the methodology deployed in the course of this research with the aim of developing a project supervisor recommendation system, the system will be evaluated along the following milestone objectives:

1. To build a dataset from scholarly publications of selected lecturers with data extracted from the publications listed on their Google Scholar profiles.
2. To provide a web-based user interface for inputting student project proposal data and displaying the resultant machine learning recommended project supervisor.
3. To develop a suitable model with a text similarity algorithm that can be integrated into the system.
4. To Introduce administrator privileges into the management of the overall system, which can be updated by an assigned system admin to update the current list of supervisors' bio and the supervisors' publications data.

Further assessment will focus on determining the accuracy and quality of the system's suggestions.

The study's first phase involves outlining the process used for dataset collection, whereby a CSV dataset including supervisors' bio-data and supervisors' past research data was acquired. This section examines the technical implementation details of the recommendation algorithm, with a focus on the use of content-based techniques, particularly the use of cosine similarity as a metric for measuring the similarity between proposed student project profiles and supervisor research profiles. The integration of the algorithm within the Django framework project is also explained. Moreover, the evaluation process encompasses the collection of student input, the implementation of the recommendation algorithm, and the examination of the system's suggestions in comparison to the ground truth in order to evaluate their accuracy and efficacy.

4.3 Results Presentation

The project supervisor recommender system is implemented as a web application, including two distinct sections: the Admin Section and the User Section. The recommendation system could be further categorized into two distinct components: The Front-end and the Backend. Figure 4.1shows the Front-end and Backend component of the Project Supervisor Recommender System.

1. The Front-end encompasses many components, including the student's query form page, the list of prospective supervisors' page, the consequent project supervisor suggestion result page, and the Admin web pages.
2. The Backend, including the database and machine learning components, maintains the overall operation of the system.

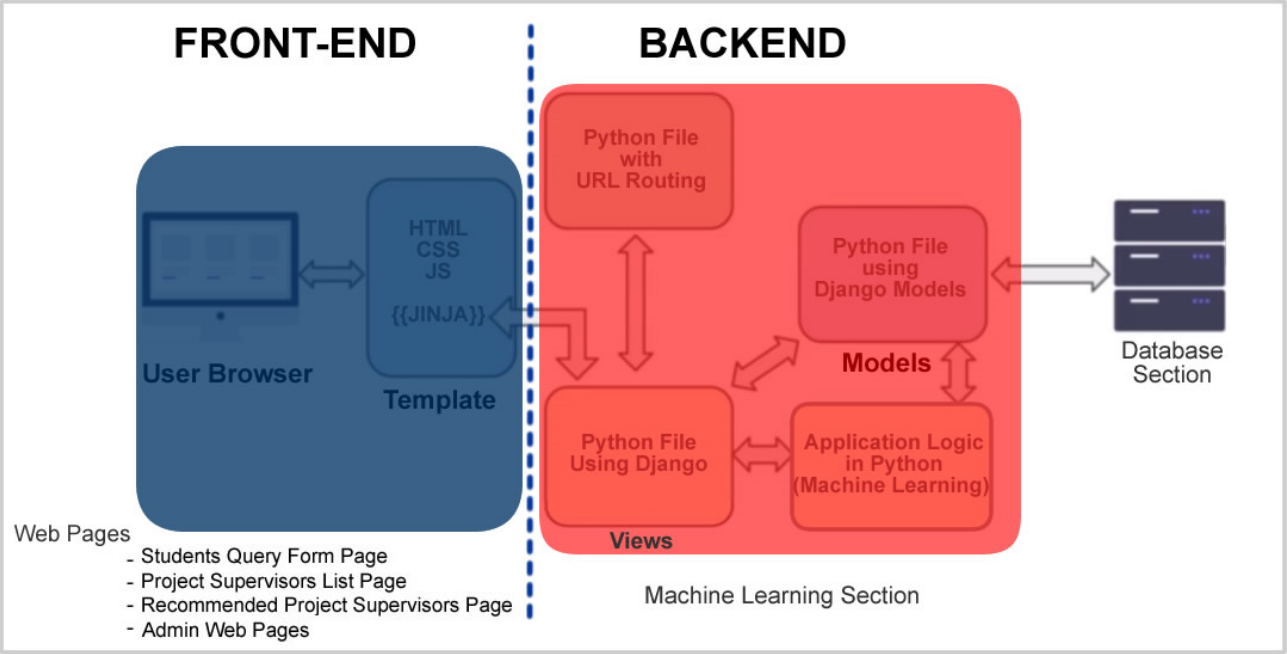

Figure 4.1: The Front-end and Backend of the Project Supervisor Recommender System

4.3.1. Students Query Form Page

Figure 4.2 shows the Students Query form interface where the user fills out the form containing the student's proposed project title, keywords and abstract before clicking the Recommend Supervisor button to get results from the recommendation system.

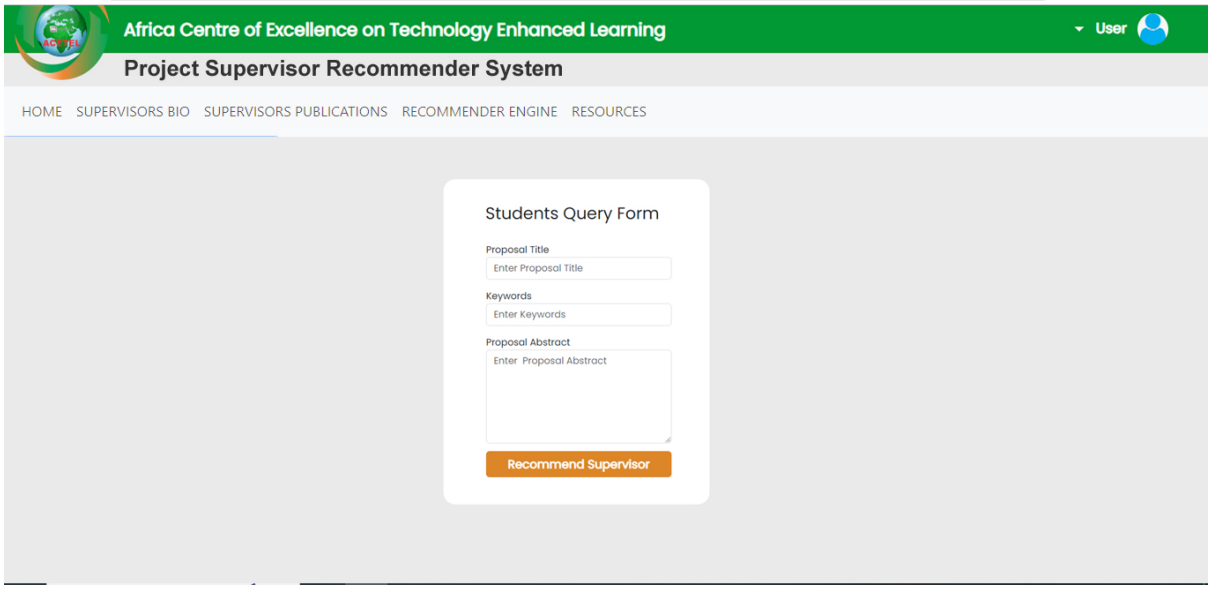

Figure 4.2: Students Query Form of the Recommender System

4.3.2. Project Supervisors List Page

Figure 4.3 shows the Project supervisors' list page. It contains list of supervisors that the System Admin had previously captured in the dataset in the supervisors short bio data dataset in the form of spreadsheet and turned into supervisors_bio table in the database. The data attributes gathered in the supervisors_bio data include prospective supervisors name, gender, email and phone.

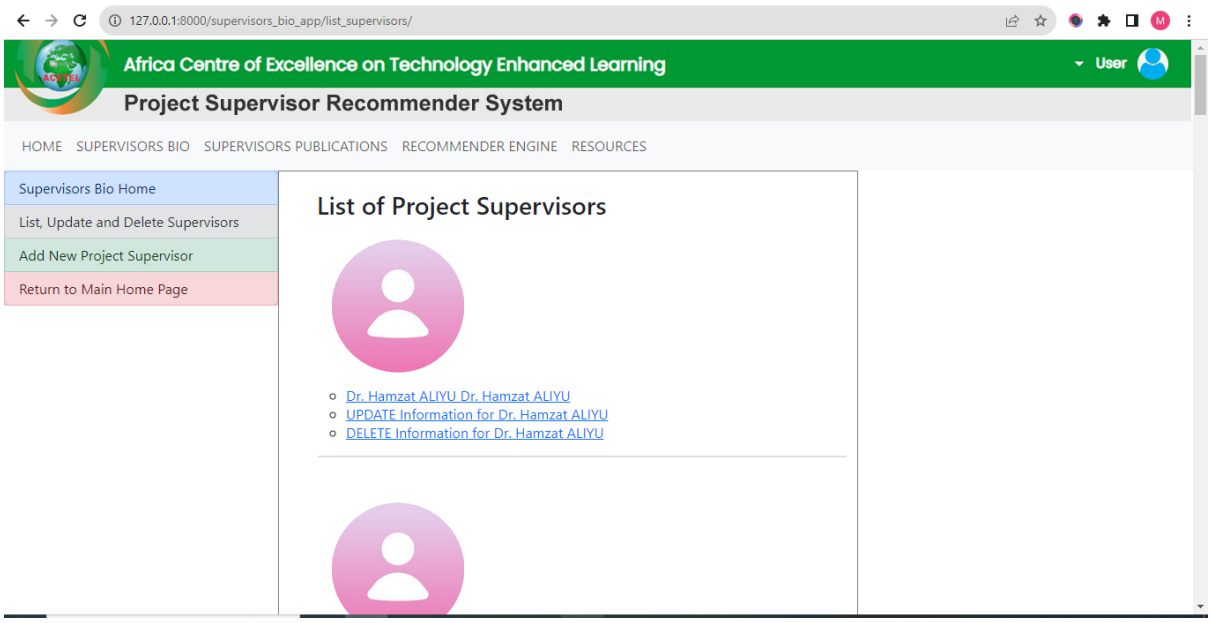

Figure 4.3: Project Supervisors List

4.3.3 Recommended Project Supervisors Page

Figure 4.4 shows a Recommended Project supervisors' page. It contains list of supervisors that the System Admin had previously captured in the dataset in the supervisor's short bio data dataset in the form of spreadsheet and turned into supervisors_bio table in the database. The

data attributes gathered in the supervisors_bio data include prospective supervisors name, gender, email and phone.

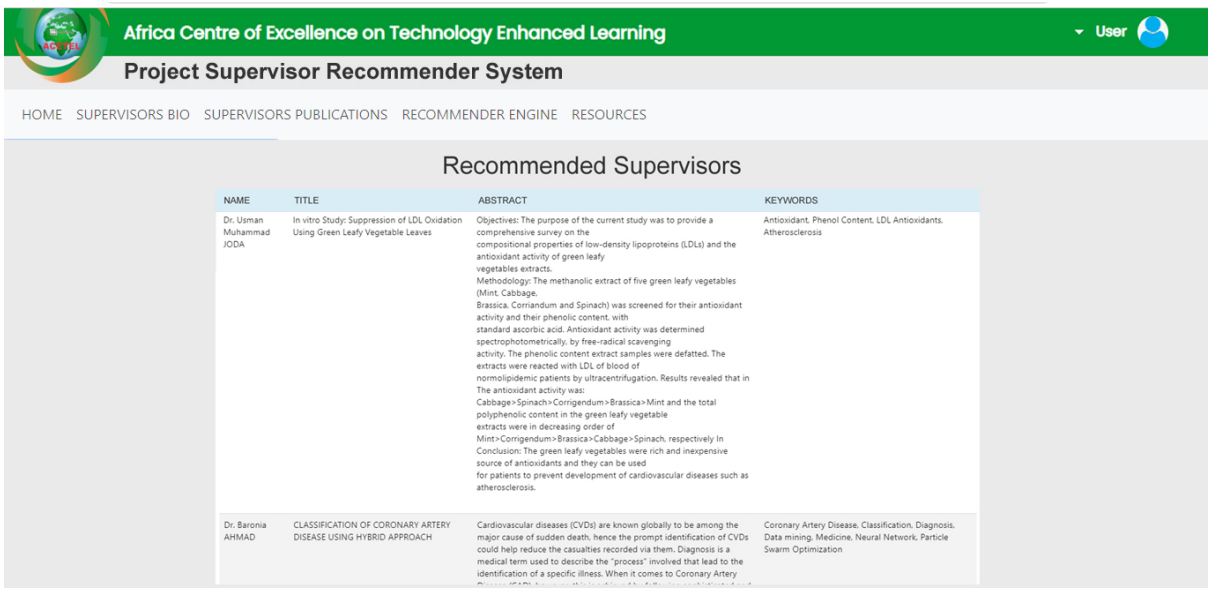

Figure 4.4 A Sample Recommended Project Supervisors' page

4.3.4 Admin Web Pages

Figure 4.5 shows the Django Recommendation System Admin Login Page while Figure 4.6 shows an Admin Portal Page. The system Admin or whatever user is given Admin privileges can frequently update the Supervisors list as well as the Supervisors' research publications as soon as more updates are available. This also improves the Machine Learning task because more fresh and growing data will eventually make the Recommendation engine more intelligent as the model learns from data. Remember, Machine learning learns from data without being explicitly programmed.

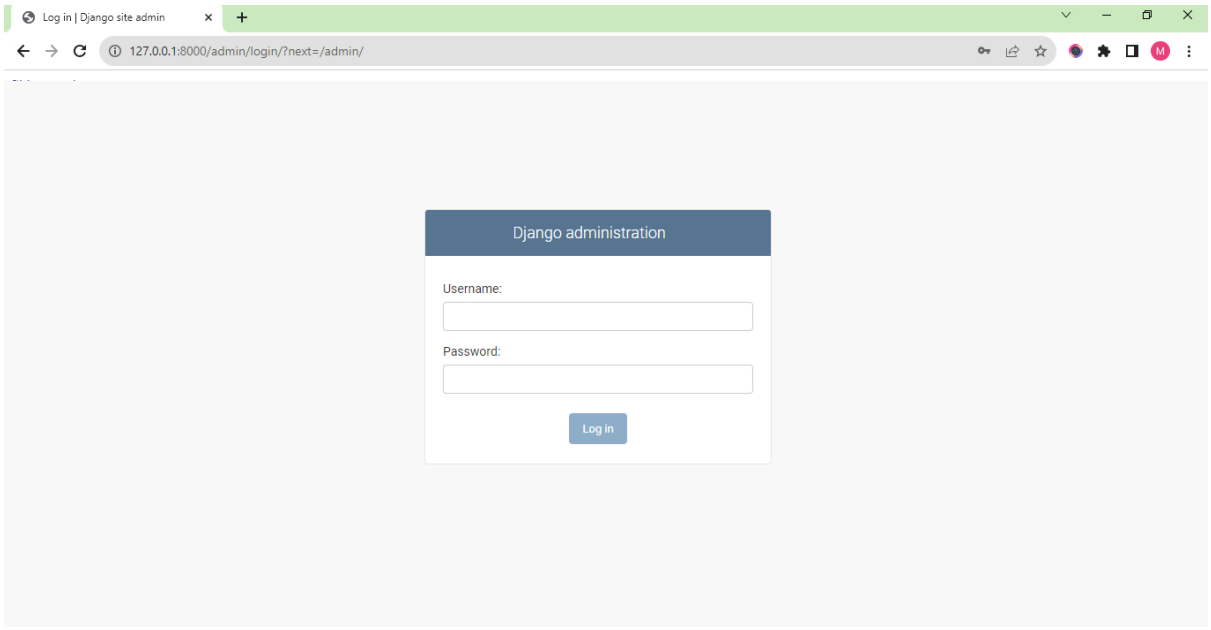

Figure 4.5: Django - Recommendation System Admin Login Page

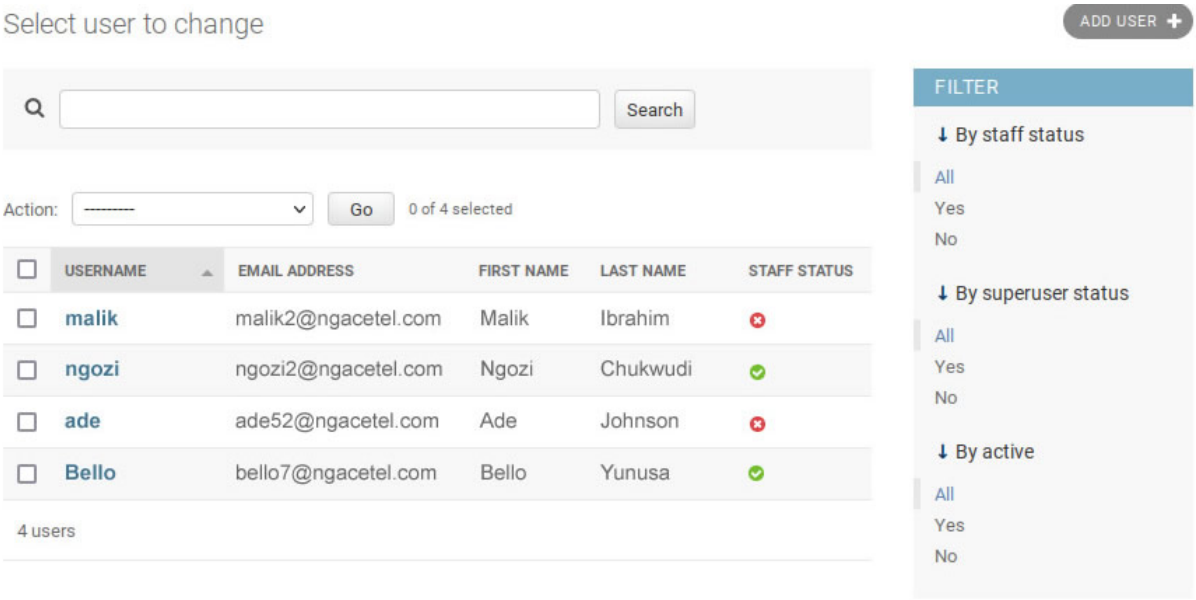

Figure 4.6 Project Recommender System Admin Page

Access to the backend is restricted to those with administrative privileges, who are mandated to sign up or log in. The authentication process for administrative personnel will be conducted via the Recommendation System Admin Login Page. However, it is not necessary for a typical user seeking access to the recommender system for project supervisor recommendations to register or log in. Although, users have the option to register for any future correspondence and get information about the project supervisor recommender system.

4.3.5 Machine Learning Section

The system is built using Django as the web framework. In this particular case, the integration of the application logic aspect of the Django web framework with the Model and View components of Django is represented as the Machine Learning section, as depicted in Figure 4.1. This integration is essential as it facilitates the collaborative functioning of these components in order to achieve the backend functionality of project supervisor recommendation. The system operates in a unidirectional manner, starting with students inputting the title, abstract, and keywords. Subsequently, the system will engage in computational processes to provide appropriate recommendations for lecturers, drawing upon data provided by users or students. Figure 4.7 illustrates the internal organization of the Django project directory, whereby each individual directory has a distinct purpose. The backend directory serves as the foundational component of the project, housing the configuration and settings for the Django applications.

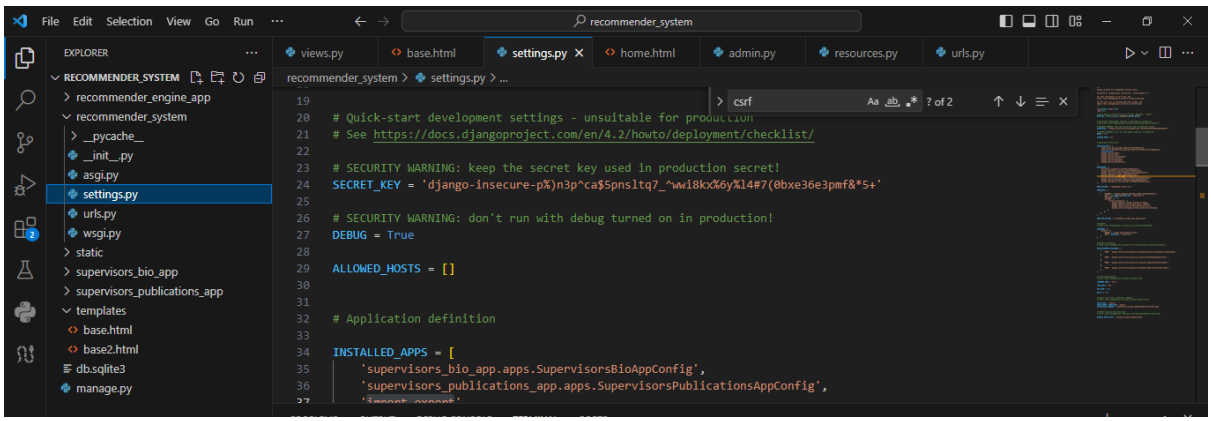

Figure 4.7: Internal organization of Django Project Directory

The cosine similarity algorithm of the content-based filtering system is also implemented in a recommendations app designated solely for that purpose as shown in Figure 4.8. It is able to collect student inputs, executing the recommendation algorithm using the implemented system, and generating supervisor recommendations based on project profiles. The results obtained from this process, such as the recommended supervisors for each student input, are presented to the views.py Python file to facilitate a visualization as presented to the user browser in Figure 4.4. This displays the top three closest matching suitable supervisors as per the submitted student project proposal data.

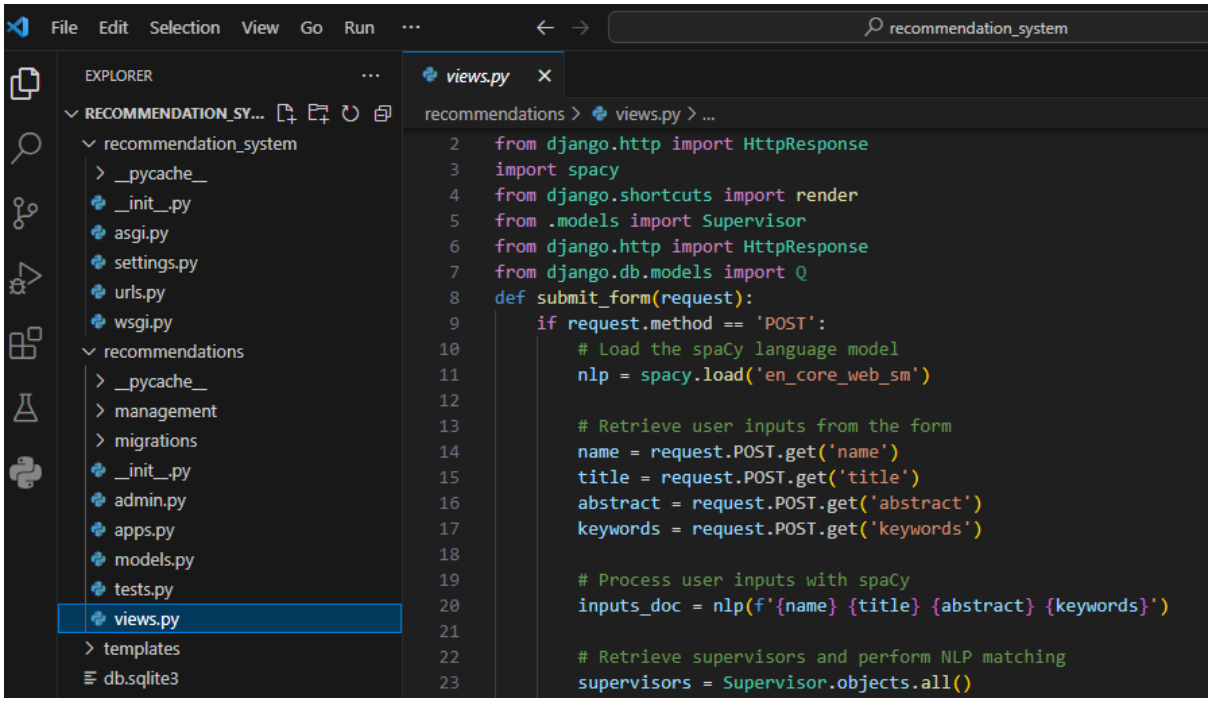

Figure 4.8: Implementation of the Recommendation System Cosine Similarity Algorithm in Django

4.3.6 The Database Section

The Project Supervisor Recommendation System is powered by data and requires significant technological resources for its implementation. From the initial stage of data collection to the

final presentation on a user interface, various processes are involved, including data analysis, planning, text mining, data mining, preprocessing, processing, filtering, and the application of machine learning algorithms. These algorithms enable the construction of intelligent models that can learn from data without the need for explicit programming. The end result is most cases is worth the effort invested. The original data provided for this study consisted of a compilation of department project supervisors. This information has been successfully included into our research by integrating it into our SQLite database. Based on the information provided on the official SQLite website, it can be broadly said that websites with a daily viewership of fewer than 100,000 should be able to effectively use SQLite. The anticipated daily number of 100,000 hits should be regarded as a conservative approximation rather than an unequivocal upper limit. Research has shown that SQLite has the ability to effectively manage a volume of traffic that exceeds the previously indicated quantity by a factor of 10. The second dataset was obtained by extracting information from the Google Scholar profile pages of the lecturers from ACETEL who were captured in this research. A total of 1,137 research papers were extracted throughout the mining procedure. Furthermore, the integration of this feature has been implemented inside the SQLite database in the Django web Framework. SQLite is a database management system that utilizes Structured Query Language (SQL) and consists of tables for organizing and storing data. The list of lecturers is stored in the supervisors_bio table, whilst the dataset of research papers that has been cleaned is stored in the supervisors_publications table.

4.4 Analysis of the Results

This research effectively integrates two significant domains of technology to address the objectives of the research. The two domains are Software Engineering, specifically focusing on Web Application Development, and Data Science, with emphasis on Machine Learning and Natural Language Processing. These three – Web Application development, Machine Learning and Natural Language Processing work hand-in-hand towards the execution of the project. The implementation of technology best practice strategies goes beyond recognizing a need and devising a technology-driven solution, it goes further to assembling relevant prerequisites and commencing their categorization into functional and non-functional requirements. The purpose and goals of the research became evident, along with the corresponding significant achievements. The choice selection and justification for using the Django web framework were outlined. It is worth noting that Tech giant companies like YouTube, Instagram, Dropbox, and Spotify, among others, also have their platforms developed with Django. This further reinforces our confidence in the system's robustness, scalability, security, authentication and administration. The recommendation system places significant emphasis on data, as it serves as its core and essential component. Therefore, careful measures were taken to ensure thorough data preprocessing prior to its use in the recommendation engine. This is particularly important since the presence of noise may significantly impede the efficiency of the system, contrary to expectations.

4.5 Discussion of the Results

The outcome derived from conducting a similarity assessment using Cosine Similarity between the student's query and supervisors' research publications indicates that the process for a student or a system user involves entering their proposed project title, keywords, and abstract

into the query form designed for students. Subsequently, they are required to click on the "Recommend Supervisor" button, as shown earlier in Figure 4.2. The following subsections provide a breakdown of the results discussion.

4.5.1 The Searched Terms Compared for Similarity

The field components of the students' query are the same as those of the supervisors' publications in the database. The three fields are:

Title: The title is the name given to a composition. It conveys the intent that surrounds the subject of the project in simple clear terms.

Keywords: Keywords are search terms that should quickly lead one to a search intent. Keywords are not careless words; they must closely match the contents of the project.

Abstract: a brief statement or account of the main points summarizing a composition. Abstract has universally accepted standards and components for best practice. The following aspects or components should be included in a well-written abstract:

- The research problem
- The aim, goals and objectives of the research
- The research methodologies
- The conclusion of the research

A combination of this trio (Title, keywords and abstract) is what is passed as a single document for each record for analysis in our recommendation engine.

4.5.2 TF-IDF Metric in Vectorization

TF-IDF is a highly useful metric for assessing a term's importance in a document. TF-IDF has two components: TF (Term Frequency), and IDF (Inverse Document Frequency). The way that term frequency functions is by examining how frequently a certain term appears in relation to each row of data or record in our supervisors_publications table, which is equivalent to each supervisor's individual publication. Conversely, inverse document frequency examines the frequency (or rarity) of a term inside the corpus. The IDF is calculated as follows with this formula.

$$\text{idf}(t,D) = \log\left(\frac{N}{\text{count } d \in D : t \in d}\right)$$

Where t, is the term (word) for which we want to measure its popularity.
The number N represents the number of documents (d) in the corpus (D).
The denominator is just the number of documents that include the term, t.

In cases where a term does not occur in the corpus at all, resulting in a divide-by-zero error, a solution is to add 1 to the current count. As a result, the denominator is (1 + count). Scikit-Learn, a popular Python library, handles it with the following formula.

$$IDF(t) = \log \frac{1+n}{1+df(t)} + 1$$

Whereas the normal formula where a term occurs in the corpus is given as:

$$IDF(t) = \log \frac{n}{df(t)}$$

IDF is needed to assist in correcting the appearance of terms like "and", "is", "the", and so on, which appear often in an English corpus. So, by using inverse document frequency, we are able to reduce the weighting of common phrases while increasing the significance of infrequent terms.

4.5.3 Combining TF and IDF: TF-IDF

TF indicates how frequently a term appears in a document, whereas IDF indicates the comparatively uncommonness of the term in the collection of documents. Our final TF-IDF value, in this case, can be obtained by multiplying these numbers together. This is shown with the following formula:

$$tf\ idf(t, d, D) = tf(t,d) \cdot idf(t, D)$$

4.5.4 TF-IDF Use Cases

TF-IDF has use cases in several applications, including:

1. **Applying TF-IDF to information retrieval.**
   Search engines are a typical example of how TF-IDF is used in the information retrieval domain. A search engine can utilize TF-IDF to assist rank search results based on relevance, with results that are more relevant to the user having higher TF-IDF scores. This is because TF-IDF can inform you about the relevant importance of a word based on a document.

2. **Applying TF-IDF for keyword extraction and text summarizing**
   Using this method, one may ascertain which words are most significant since TF-IDF assigns weights to words depending on their significance. This may be used merely to find keywords (or even tags) for a text, or it can be used to assist in summarizing articles more effectively.
3. **Feature extraction for text classifications**
4. **Document clustering/grouping**
5. **Natural language processing.**

4.5.5 TF-IDF, Cosine Similarity and the Basis for Natural Language Processing in Recommender System

Since Machine Learning algorithms frequently work with numerical data, vectorization - a procedure that transforms textual data into a vector of numerical data must come first when working with textual data or any natural language processing (NLP) activity. The process of TF-IDF vectorization is figuring out each word's TF-IDF score in relation to the content and then putting that data into a vector. As a result, every document (publication) in the corpus (collection of publications) would have a unique vector that contained the TF-IDF score for each and every word in the collection of documents. With these vectors, we can use cosine similarity to determine how similar the TF-IDF vectors of the supervisors' publications data and query input from a student project proposal are to one other.

As notably seen by the speed with which search engines provide appropriate search results for searches with TF-IDF and Cosine similarity analysis, without doubt, it is still one of the most prevalent techniques to analyze textual data. Additionally, they help websites rank better in search results pages (SERPs) by demonstrating how close they are to a certain query.

4.5.5.1 How TF-IDF is Computed in the Recommendation Engine

The TF-IDF score of the word reveals the significance or importance; as a term gets closer to zero, its score declines.

Table 4.1 shows the sample data used in calculating the vectorization result of three publications. One is doc1 which is the student project proposal, while the remaining doc2 and doc3 are from the supervisors' publications dataset. From the table, the title, abstract and keywords of doc1 were merged and passed into the doc1 variable in Figure 4.9. The same constituents (title, abstract and keywords) each of doc2 and doc3 are merged and passed into doc2 and doc3 respectively.

Table 4.1 Sample Documents used to Calculate the Vectorization Result of Three Publications.

Documents	Author	Title	Abstract	Keywords
doc1 (Student Project Proposal)	Student	Machine Learning to Predict Cardiovascular Risk	To analyse the predictive capacity of 15 machine learning methods for estimating cardiovascular risk in a cohort and to compare them with other risk scales, we calculated cardiovascular risk by means of 15 machine-learning methods and using the SCORE and REGICOR scales and in 38 527 patients in the Spanish ESCARVAL RISK cohort, with 5-year follow-up. We considered patients to be at high risk when the risk of a cardiovascular event was over 5% (according to SCORE and machine learning methods) or over 10% (using REGICOR). The area under the receiver operating curve (AUC) and the C-index were calculated, as well as the diagnostic accuracy rate, error rate, sensitivity, specificity, positive and negative predictive values, positive likelihood ratio, and number needed to treat to prevent a harmful outcome. The method with the greatest predictive capacity was quadratic discriminant analysis, with an AUC of 0.7086, followed by Naive Bayes and neural networks, with AUCs of 0.7084 and 0.7042, respectively. REGICOR and SCORE ranked 11th and 12th, respectively, in predictive capacity, with AUCs of 0.63. Seven machine learning methods showed a 7% higher predictive capacity (AUC) as well as higher sensitivity and specificity than the REGICOR and SCORE scales. Ten of the 15 machine learning methods tested have a better predictive capacity for cardiovascular events and better classification indicators than the SCORE and REGICOR risk assessment scales commonly used in clinical practice in Spain. Machine learning methods should be considered in the development of future cardiovascular risk scales.	machine learning, cardiovascular, patients, regicor, diagnostic
doc2	Dr. Baronia AHMAD	An Improved Classification Method for Diagnosing Heart Disease using Particle Swarm Optimization	Today, the diagnosis of some of the major cardiovascular diseases, for example Coronary Artery Diseases (CAD), heart rhythm problems, Ischemic, Atrial Fabrication and so on is generally accomplished by following modern and costly therapeutic strategies performed in well-equipped medical institutions. In addition, these procedures usually require the application of invasive methods by only highly qualified medical experts. Although this approach gives a high degree of accuracy regarding diagnosis, but the number of patients having access to this facility is limited. Hence, the development of an easily accessible method for cardiovascular disease diagnosis is highly desirable. In this research work, the past work which employs the use of Deep Neural Network (DNN) for the diagnosis of heart disease is extended, CAD for four (4) different datasets was used with Particle Swarm Optimization (PSO) assisted method for DNN to enhance the accuracy of diagnosing heart disease, which is very complex in the healthcare practices was proposed. The aim of this research is to enhance the accuracy of diagnosing heart disease. A conceptual framework to analyze CAD heart disease was developed with the end goal to improve human services partner for specialists with convenience in the advancement of treatment of disease, also integration of the PSO training algorithm to train the DNN and finally, evaluation and validation of the performance of the proposed hybrid model with benchmark model Neural Network Classifier was carried out to obtain a comparison of the proposed model to the existing classification models. The research datasets are obtained from data mining repository of the University of California, Irvine (UCI) Machine learning repository. Experimental results show that training DNN using PSO results 94%, 94.9%, 95.5%, 95.0% in accuracy for Cleveland, Hungarian, Switzerland, and VaLong beach respectively. The technique puts forth can be used in CAD detection.	Classification, Heart disease diagnosis, Coronary Artery Disease, Machine learning, Particle Swarm Optimization, Neural Network
doc3	Prof. Rasheed Gbenga JIMOH	Cloud-based IoMT framework for cardiovascular disease prediction and diagnosis in personalized E-health care	The advent of Internet technology has provided the opportunity to connect billions of computers and devices globally. The advantages offered by Internet technology have been extended to Internet-of-things (IoT). The extension of IoT to include devices in the medical domain with reference to Internet of medical things (IoMT) has improved the quality of personalized health-care services. However, the huge volume of big data generated by IoMT sensing devices in the health-care environment is of great concern. This has created several challenges including identification of effective techniques to mine this huge amount of data. Thus, cloud-based applications are playing significant roles in addressing secure data storage and efficient service delivery. IoT technology integrated into the cloud enhances health-care service delivery through effective resource utilization, storage, energy, and computational capability. However, despite the huge investment in the health-care industry, the potent	Cloud computing, Cardiovascular disease, Internet-of-things, Sensors, Health care

Figure 4.9 shows a TF-IDF vectorization result obtained while comparing a Student Query with two supervisors' publications.

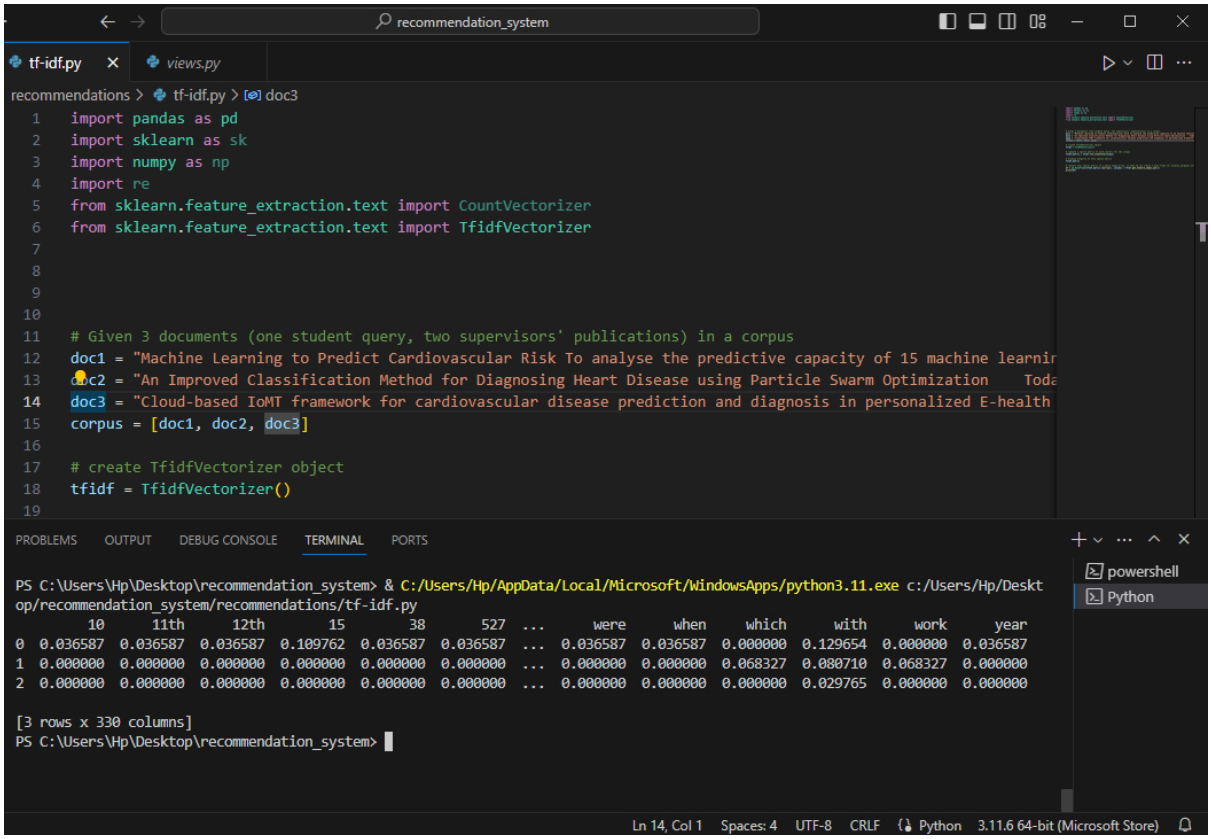

Figure 4.9 TF-IDF Vectorization Result of three Sample Documents.

The result in Figure 4.9 shows that there are three rows, which correspond to the three documents that are being compared, and 330 columns (with a few hidden columns inserted to display the initial and final few). Another thing to note is that, although there are a few non-zero values in the returned matrix, there are many zero values since certain words are absent from the provided document. Actually, a sparse matrix is the default output of the "TfidfVectorizer" function, which is a more effective method of handling a matrix with a large number of zeros. The code's "toarray()" method would enable us to create a dense array. This was done to change it from a sparse matrix to a dense numpy array so that we could only use it for display when creating a data frame.

In practice, Sparse matrix is valued over Dense NumPy array for TF-IDF for several considerations including:

i. In the event that we transform a set of raw text documents into a TF-IDF feature matrix, the majority of the values in the resultant matrix are zero since each document comprises just a small part of the whole vocabulary. Storing these resultant zero values in a dense numpy array can result in high computational memory usage, particularly if the dataset is huge.

ii. Conversely, sparse matrices just keep track of the non-zero values and the row and column indices that go with them. Because of this, storing big matrices with a substantial percentage of zero values in sparse matrices is more memory-efficient.

iii. Sparse matrices not only save memory but can also accelerate calculations since many numerical libraries are designed to work with sparse matrices and can take use of their sparsity to carry out operations more quickly. So, employing a sparse matrix is a more effective and useful approach to describe the data for TF-IDF, where the majority of the values in the matrix are zero.

4.5.5.2 Computing TF-IDF for a New Query

Upon obtaining the document-term (publication-term) matrix for a training corpus, we may utilize the "transform" function to calculate a new document's vector representation (student proposal query) by drawing on the knowledge we have acquired from the training corpus. The IDF matrix is still taken from the training corpus, but the TF matrix is entirely dependent on the new document (student proposal question) underneath. These are the causes.

1. We only compute IDF once if we think the training corpus is sufficient. This makes computing TF-IDF for a new document super-efficient.
2. If the new document will NOT be part of the training corpus, we don't need to include it in IDF.

The screenshot of the textual data of our sample new document (consisting of title, abstract and keywords) is shown in Figure 4.10.

CLASSIFICATION OF CORONARY ARTERY DISEASE USING HYBRID APPROACH	Cardiovascular diseases (CVDs) are known globally to be among the major cause of sudden death, hence the prompt identification of CVDs could help reduce the casualties recorded via them. Diagnosis is a medical term used to describe the "process" involved that lead to the identification of a specific illness. When it comes to Coronary Artery Disease (CAD), however, this is achieved by following sophisticated and costly medical procedures in well-equipped hospitals and healthcare facilities. Furthermore, these procedures usually require only highly qualified medical experts to apply invasive methods. The number of patients who have access to this facility is limited. This research employs the use of Deep Neural Network (DNN) for the diagnosis of CAD for four (4) different datasets with Particle Swarm Optimization (PSO) assisted method for DNN. The aim of this research is to enhance the accuracy of diagnosing heart disease. Developed a conceptual framework to analyze CAD, also integrated PSO training algorithm to train DNN. Finally, evaluate and validate the performance of the proposed hybrid model with benchmark model. The research has shown that PSO is an effective evolutionary computing technique that improves the accuracy of classification. PSO selects the most optimum weight for DNN and increases the classification accuracy. The percentage improvement of the PSO hybridization to DNN are 8.8%, 11.4%, 3.3%, and 11.0% for Cleveland, Hungarian, Switzerland and ValongBeach respectively. The method put forward can improve patient diagnosis reliability and performance as it concerns CAD detection. Figure 4.11 shows the computation code for a new document and the resultant TF-IDF scores

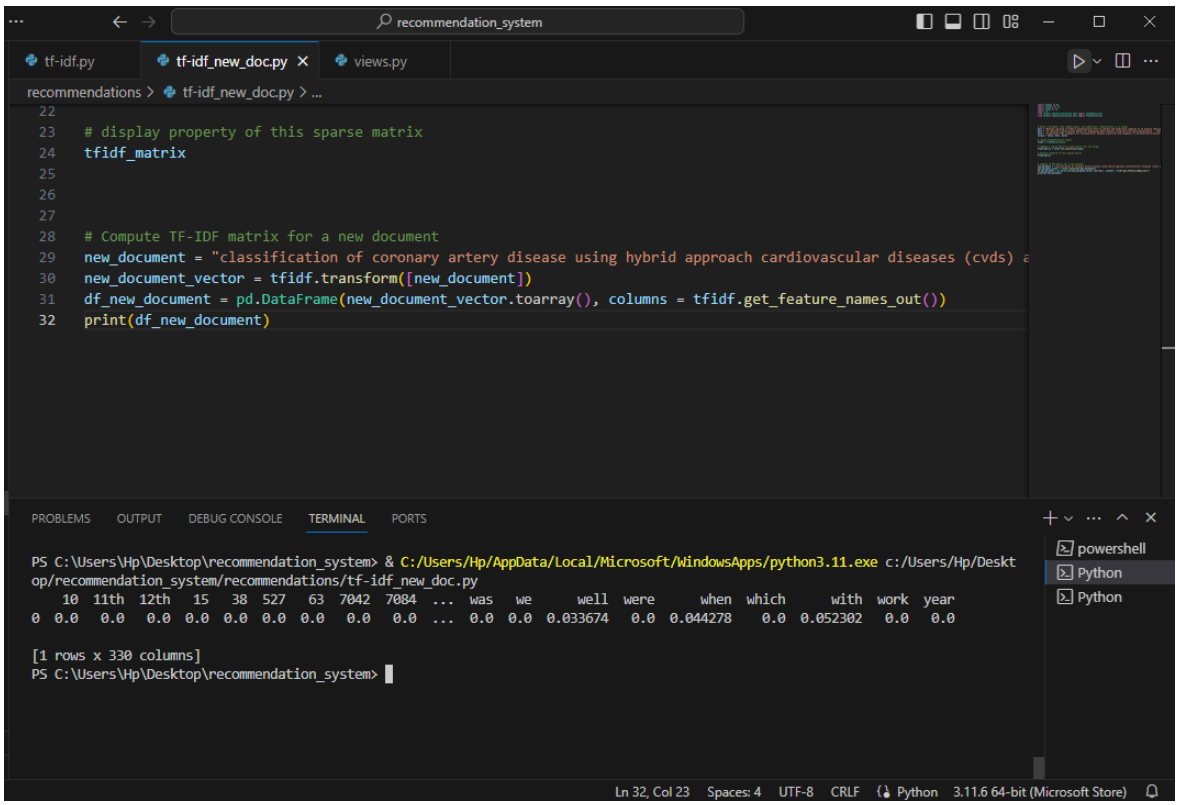

Figure 4.11 Computing TF-IDF for a new document

4.5.5.3 Computing Cosine Similarity

A common metric in information extraction and natural language processing is cosine similarity, which quantifies the similarity between two vectors. The process of calculating the cosine of the angle between the two vectors yields a score that can vary from -1 to 1. A score of -1 denotes complete dissimilarity between the vectors, 0 indicates orthogonality (i.e., no correlation), and 1 indicates identicality.

Here's the cosine similarity formula for calculating similarity between two vectors:

$$\text{Cos}(x, y) = x \cdot y / (||x|| * ||y||)$$

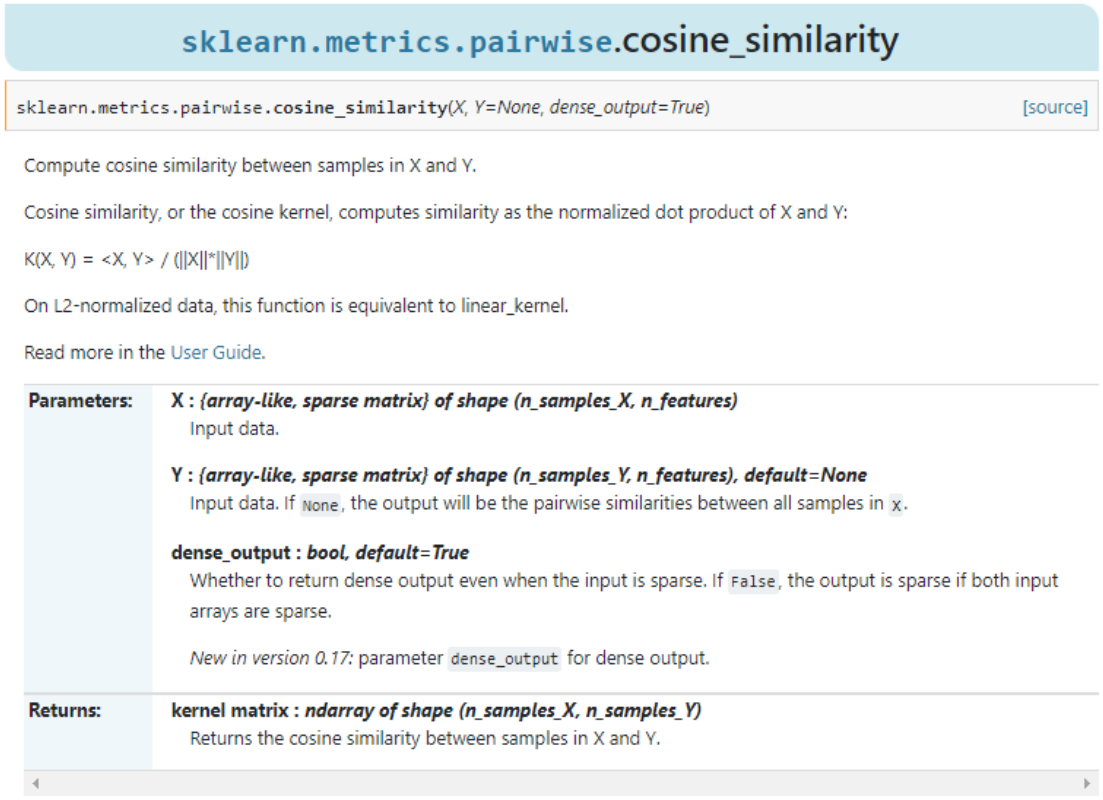
When it comes to natural language processing, we use methods like TF-IDF to compute the cosine similarity value between two words or texts inside a corpus according to their vector representation. The cosine similarity value in this instance can range from 0 to 1, with a value of 1 denoting perfect resemblance between two words or documents and a value of 0 denoting the opposite.

4.5.5.4 Exploring Python Libraries for Cosine Similarity

The mathematical formula makes it simple to determine cosine similarity, as was covered in the previous chapter. But what happens should one need to quickly compute the similarities but the data gets too big? Python is perhaps the most widely used programming language for these kinds of jobs, and part of its versatility comes from the large number of libraries that it has. The most often used Python libraries for computing cosine similarity are:

1. NumPy is a basic Python library for scientific computing that includes vector magnitude and dot product functions, both of which are required for the cosine similarity calculation.
2. SciPy: a technical and scientific computing library. Its function may determine the cosine distance, which is equal to cosine similarity minus one.
3. Scikit-learn: provides effective and straightforward tools for analyzing predictive data and includes a feature that allows for the quick and easy computation of cosine similarity.

The only library among the ones listed above that can directly determine the cosine similarity between two vectors or matrices is scikit-learn, which is a great tool for machine learning ardent supporters and data analysts. To achieve that, it offers the **sklearn.metrics.pairwise.cosine_similarity** function; we'll demonstrate how it operates using an example. Cosine similarity values between two vectors will be calculated using the **sklearn** "cosine_similarity" function.



sklearn.metrics.pairwise.cosine_similarity

sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True) [source]

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

K(X, Y) = <X, Y> / (||X||*||Y||)

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the User Guide.

Parameters:

X : *{array-like, sparse matrix} of shape (n_samples_X, n_features)*
Input data.

Y : *{array-like, sparse matrix} of shape (n_samples_Y, n_features), default=None*
Input data. If `None`, the output will be the pairwise similarities between all samples in `X`.

dense_output : *bool, default=True*
Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

Returns:

kernel matrix : *ndarray of shape (n_samples_X, n_samples_Y)*
Returns the cosine similarity between samples in X and Y.

Figure 4.12 Cosine Similarity Function in SKLearn Source:[60]

It is evident from the SKLearn parameters that the "cosine_similarity" function can accept both "ndarray" and "sparse matrix." It is always advised to use a sparse matrix when working with big corpuses.

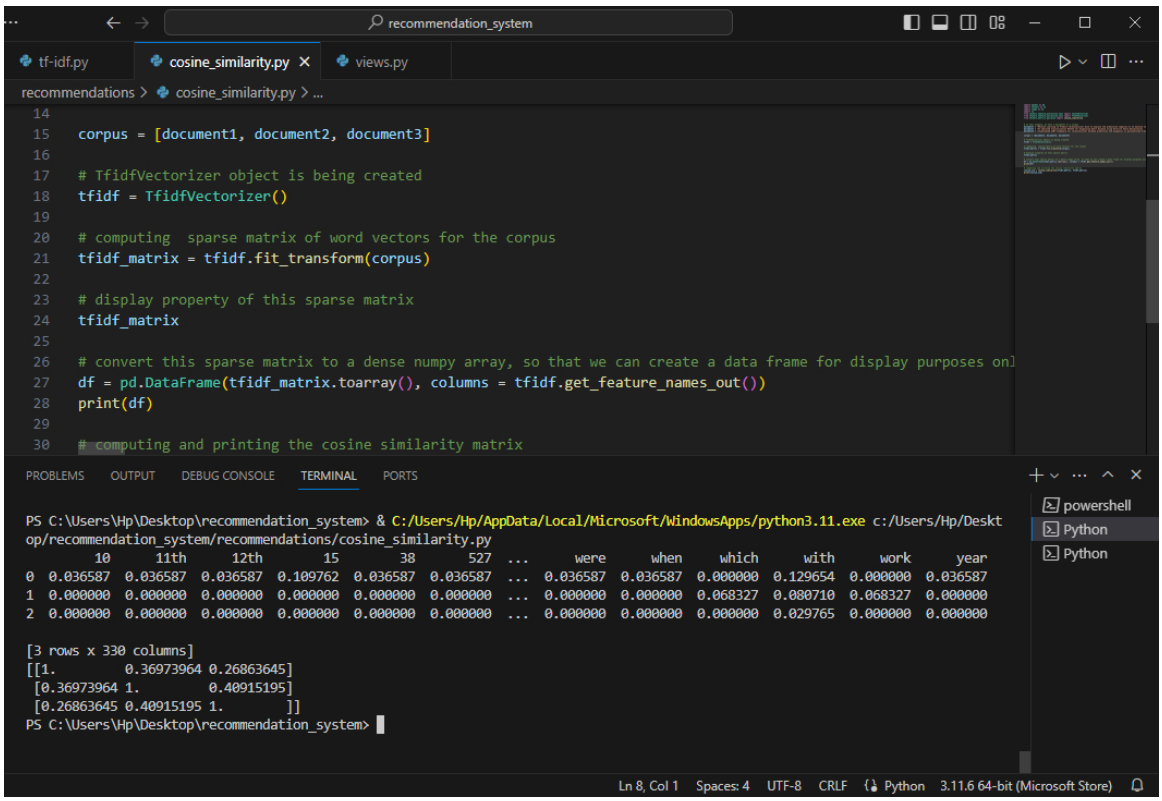


Figure 4.13 Computing Cosine Similarity

A matrix of word frequency in each of the three documents is displayed in the first result from Figure 4.13. This is where the cosine similarity is calculated, leading to the final matrix. An N by M matrix, with N representing the size of the corpus x and M representing the size of the corpus Y, would be returned by the cosine similarity. Next, the cosine similarity of two documents compared or paired from the two corpora is represented by every single element in the matrix. The contents of document1 are represented in the first column. The cosine similarity to each of the three other documents is represented by each row in the first column. In this instance, it indicates that document1 and itself have a cosine similarity score of 1. The whole diagonal equals 1 for the same reason: it shows the cosine similarity of each document to each other. The cosine similarity between the vectors of document1 and document2 is displayed in the next row of the first column; it is 0.36973964. Finally, we get the cosine similarity between the vectors of document1 and document3, which is 0.26863645. However, let us recall that our comparison is between a student project proposal query which is contained in document1 and two other documents (document2 and document 3). As a high cosine similarity score suggests a strong match, we shall order the cosine similarity values in descending order (highest to lowest). So, if we are to rank the cosine similarity scores, document2 with cosine similarity score of 0.36973964 which is higher is closer to document1 than document3 with 0.26863645 similarity score which is lower. Using the Template component of Django, the Django framework's View component sends the cosine similarity output to the user interface, where it is presented in an attractive and human-readable format.

4.6 Implications of the Results

The efficacy and dependability of this technological solution in facilitating decision-making about the selection of project research supervisors for students has been established. In this study, we analyze the wider ramifications of the findings derived from the assessment of the

supervisor referral system. The practical uses and possible advantages of the system are examined within the context of academic institutions or research settings. The optimization of student-supervisor matching has the potential to enhance the research experience, optimize project results, and foster efficient collaborations. In addition, we have taken note of the obstacles and challenges encountered that need to be addressed and taken into account while adopting and executing a recommendation system of this kind for further research. Additionally, this analysis offers valuable insights into the possible utility and influence of the system's outcomes within the framework of supervisor-student matching.

4.7 Benchmark of the Results

The human brain is capable of distinguishing between few situations on the basis of minor distinctions in characteristics. This has been the case with the manual selection process as against the automated supervisor suggestion process. The model built on the algorithm was developed to simulate the brain's perception of distinctions. In our analysis, we recognized the similarity between a student’s query and one thousand one hundred and thirty-seven (1,137) research publications of supervisors. Running the data through the model and calculating the cosine similarity value, we confirmed the top three most similar to the student’s proposal input. When their cosine similarity value is close to 1, the projects are very similar and when the cosine similarity value is near zero, they are dissimilar. This project supervisor recommendation system model is particularly valuable because it can handle supervisor recommendations effectively and scale up even with a large pool of research publications.

CHAPTER 5: SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Summary

Automating Project supervisor selection process in academic institutions remains the key to getting the best from the student researcher and their supervisors who not only provide guidance but mentoring as well. The human brain lacks the capacity to store and recall vast amounts of data with exceptional speed and accuracy. This is particularly advantageous for making well-informed decisions and for contributing to the existing body of knowledge. The research undertaken so far on recommending project supervisors to students using Machine Learning, especially with the results obtained, has shown promising outcomes, indicating its potential to enhance research performance.

5.2 Conclusion

In order to process natural language text and extract meaningful information from a particular word or phrase using machine learning techniques, the text or string must be transformed into Word Embeddings, which are sets of real numbers. A technique in natural language processing known as "word embeddings" or "word vectorization" maps words or phrases from a lexicon to a matching vector of real numbers. This mapping is done to determine word predictions, word similarities, and word semantics. An effective technique called TF-IDF (Term Frequency - Inverse text Frequency) makes use of word frequency to assess a word's relevance to a particular text. It is an easy way to weigh words, and as such, it could function as an incredible starting point for a lot of other activities. Creating search engines, document summaries, and other work in the fields of machine learning and information retrieval falls under this category. Using TF-IDF approaches, we calculate the cosine similarity value between two words or documents inside a corpus for the purpose of natural language processing. The cosine similarity value in this instance can range from 0 to 1, with a value of 1 denoting perfect resemblance between two words or documents and a value of 0 denoting the opposite. In this research, we used it mostly for information retrieval and machine learning tasks rather than only for search. Prior to running our data through a cosine similarity check, we could recall that TF-IDF was instrumental in the vectorization of our textual data. Text can be vectorized using TF-IDF to be transformed into a form that is more suited for Machine Learning and Natural Language Processing (NLP). Though it is a widely accepted approach for Natural Language Processing, it is not the only one available. Word embedding methods such as Bag-of-words, Word2Vec, BERT, and so on are also available. A brief comparison between Vectors and Word Embedding is made as follows:

1. **Bag of Words**

   Word frequency in a document can be counted using the Bag of Words (BoW) technique. As a result, every word in the document's corpus is represented by its vector. Bag of words and TF-IDF vary primarily in that Bag of words just represents a frequency count (TF) and does not include any type of inverse document frequency (IDF).

2. **Word2Vec**

   Word2Vec is an algorithm that ingests a corpus and generates sets of vectors using shallow 2-layer neural networks instead of deep ones. TF-IDF and word2vec differ in

that the former yields a statistical measure that we can apply to terms in a document and then use to form a vector, while the latter will produce a vector for a term and then require additional work to convert that set of vectors into a singular vector or another format. Moreover, word2vec considers the context of the words in the corpus, while word-IDF does not.

3. **BERT - Bidirectional Encoder Representations from Transformers**
   BERT is an ML/NLP approach created by Google that turns words, sentences, and other data into vectors using a transformer-based ML model. The following are the main distinctions between TF-IDF and BERT: While BERT considers the context and semantic meaning of words, TF-IDF does not. Furthermore, BERT's design makes use of deep neural networks, which means that it can be significantly more computationally expensive than TF-IDF, which is not subject to these constraints.

From our result analysis, we could see that the Student Project Supervisor Recommender System leverages the text analysis and recommendation system application aspects of Cosine Similarity. Most often, data scientists utilize cosine similarity to accomplish tasks related to Machine Learning, natural language processing, or other related initiatives. Among their applications are:

1. Text analysis, as seen in the example, is used to quantify the degree of similarity between texts and provides essential functionality for information retrieval systems and search engines.
2. Recommendation engines, which can offer related products, services or persons in social network apps depending on user preferences. As an illustration, based on the text similarity detected, suggest the following page in the product documentation.
3. Data clustering: This machine learning technique uses metrics to group or classify related data points, assisting in the process of making data-driven decisions.
4. Semantic similarity, which assesses the semantic similarity of words or texts when used with word embedding methods such as Word2Vec.

One of the most effective ways to assess or gauge how similar two documents are is to use cosine similarity. This similarity measuring tool functions well regardless of size. It can be ascertained without necessarily requiring the Sklearn module. However, the task will require additional effort. Hence, Sklearn makes this a lot easier.
By conducting an in-depth examination of the results obtained from the evaluation of the supervisor recommendation system, this study undertook a comprehensive analysis of the findings. The accuracy of the recommendations is evaluated through a comparison with the ground truth, which consists of established supervisor-student pairings that have been demonstrated to be successful. Additionally, we assess the system's ability to effectively employ content-based filtering methods utilized by recommendation systems, such as cosine similarity, to determine suitable supervisors based on project profiles. Numerous factors are considered in the methodology, such as the influence that keywords, project titles, and abstracts

have on the precision of the recommendations. The aim of this study is to augment our understanding of the limitations and strengths of the system inefficiently recommending suitable supervisors for students. The functionality outlined in the requirement specifications of the recommendation system operates as intended. By employing this solution, the problem of human bias is eradicated. Supervisors who possess expertise in particular domains can derive advantages from this type of student-supervisor suggestion coupling. Therefore, it can be deduced that the research being undertaken aligns with its intended aim and objectives.

5.3 Recommendations

In as much as getting the closest match of supervisors' publications to a student's project proposal is the aim of the similarity check, TF-IDF is one of the most widely used tools for word vectorization owing to its multiple advantages, which gives it an edge over other techniques. One of the best advantages of using the TF-IDF technique in our approach to finding word similarity through word vectorization is the simplicity and ease of use which TF-IDF offers in the entire process. Its calculation is simple. Another thing to note is that it is computationally cheap. Thereby presenting it as a simple starting point for text similarity calculations via TF-IDF vectorization and cosine similarity. However, for better and improved services, some issues were observed in the course of this research, mostly relating to the technology and methodologies employed in executing this project. A summary of a few recommendations is provided below.

1. **Investigating or Trying out Alternative Word Embeddings**
   At the same time, we should know that TF-IDF cannot help carry semantic meaning. Word importance in TF-IDF is based on the weights of such words, which in this case, cannot extract the context and the actual importance of the word or phrase. Much in the same way just like Bag of Words (BoW), TF-IDF does not take word order into account, hence compound nouns like "Prime Minister of Nigeria" will not be regarded as a "single unit." This also applies to negation scenarios where the sequence of the words "not going to school" vs "going to school" is essential. handling the phrases as a single entity in both situations involves handling "prime_minister_of_nigeria" and "not_going_to_school" with Named Entity Recognition (NER) and underscores. Due to TF-IDF's susceptibility to the dimensionality curse, memory inefficiency is another significant challenge. Remember that the vocabulary size corresponds to the length of TF-IDF vectors. While this might not be a problem in some categorization scenarios, as the quantity of documents rises, it might become unmanageable in other scenarios especially when the computing resources is low. Therefore, it could be warrant trying out some of the alternatives earlier discussed like Word2Vec, BERT etc.

2. **Enhanced Data-gathering Procedure**
   The data obtained by web scraping from Google Scholar is in its original form and may include irrelevant information. Prior to its effective use, the data must undergo many refining procedures. Therefore, there is a need for an enhanced data-gathering procedure.

3. **Availability of More data**

The effectiveness of a project supervisor recommender system that utilizes the content-based filtering technique will be highly dependent on the content included in each item. An increase in available data from supervisors will result in improved intelligence and recommendation outcomes.

4. **Improved Computing Resources**

   It is important to note that the current hardware and software resources used in the present research implementation are capable of adequately meeting the computational requirements of the supplied data. Nevertheless, the inclusion of greater content will inevitably impact the overall execution time. Therefore, there is a need to increase resource allocation in order to enhance services as data volume increases. The more extensive the data, the longer the system will need to conduct computations. Therefore, it is vital to use a cloud server that has substantial computational capabilities.

5.4 Future Research Directions

Further research direction will be to take into consideration the observations and recommendations highlighted in section 5.3. Besides that, giving the project more value would necessitate adding more interesting modules rather than just a search platform for student-supervisor matching. Other academic components that can enhance academic research can be incorporated, which can lead to making it a world-class academic research hub with the integration of more emerging technologies, including Big Data, Cloud Computing, Artificial Intelligence, Digital Trust, etc.

BODY FAT PERCENTAGE PREDICTION USING A DEEP LEARNING MODEL BASED ON BODY MASS INDEX (BMI)

BY
ISAH SAFIYA
ACE22110012

A Thesis submitted in Partial Fulfilment of the Requirements for the Award of the Master in Science (MSc.) in Artificial Intelligence at the African Centre of Excellence on Technology Enhanced Learning,
National Open University of Nigeria

Declaration

I declare that the work of this thesis entitled “BODY FAT PERCENTAGE PREDICTION USING A DEEP LEARNING MODEL BASED ON BODY MASS INDEX (BMI), has been carried out by me in Department of Artificial Intelligence, under the supervision of Dr. Olaide Oyelade. The information derived from the literature has been duly acknowledge in the text and a list of references provided. No part of this work has been presented for another degree or diploma at this or any other institution.

Isah Safiya

---------- ---------- ----------

Name Signature Date

Certification

This thesis titled "BODY FAT PERCENTAGE PREDICTION USING A DEEP LEARNING MODEL BASED ON BODY MASS INDEX (BMI) by Isah Safiya meets the regulations governing the award of Masters in Science (MSc.) of the National Open University of Nigeria and is approved for its contributions to knowledge and literary presentation

---------- ----------

Dr Olaide Oyedele Date

(Main Supervisor)

---------- ----------

Head of Department Date

---------- ----------

Dean, SPGS Date

Dedication

This thesis is dedicated to Almighty Allah for the gift of life, strength and knowledge to embark on this work.

It is also dedicated to my dearest Husband, Mr Isah Muhammed for his encouragement and support throughout this program, words can never express how I appreciate you.

Acknowledgements

In the name of Allah, the most Gracious, the most merciful. I give all praise to Allah for this successful journey.

I would like to extend my profound appreciation to my ever- supportive Supervisor, Dr Olaide Oyelade for his patience and relentless effort in making sure this work was successful. May God reward him richly

I would like to express my heartfelt gratitude to my wonderful family; My Husband, who has always been massively supportive, my beautiful daughters: Fauziya, Kamila, Khadijah and Azeezah especially Azeezah who came to this world while pursuing this journey.

I want to also use this medium to appreciate my Course mates especially Mr Cheter, Mrs Roshida, and Mr Orowho for taking their time to explain when I have any difficulty. Although we haven't met in person i hope to see you all someday. Thank you so much

Abstract

The Body Mass Index (BMI), a widely used metric to assess a person's weight in relation to their height, is a useful tool for determining a person's body fat percentage and the diseases that may be linked to greater body fat levels. Body fat percentage is a more accurate measure of adiposity than body mass index (BMI) in populations with excess fat-free mass. A higher BMI increases the chance of having certain illnesses such high blood pressure, heart disease, type 2 diabetes, gallstones, respiratory problems, and multiple types of cancer. The deep learning model: Feed-Forward Neural Network (FNN) was employed in the study as the training method. It was discovered that a two hidden layered design with 32 and 16 neurones, respectively, and ReLU activation was the best configuration for the network. The inputs were age, gender, and BMI; the output was body fat %. The data were analyzed and compared using keras framework of Python programming. Six FNN architectures were created and assessed using hyperbolic tangent and sigmoid functions. The ideal configuration was determined, with Model 3 being the most promising. It demonstrated a balanced classification performance with 70% accuracy, 75% precision, and 81% F1-score, effectively navigating class imbalance in the BMI dataset.
The study shows Feed-forward Neural Networks (FNNs) can predict body fat percentage from BMI data, demonstrating its potential as a non-invasive method. Age is identified as a key factor influencing fat percentage, enhancing accuracy.

Chapter 1: Introduction

1.1 Background to the study

The World Health Organization, World Obesity Federation, Canadian Medical Association, and American Medical Association all recognized obesity as a chronic, relapsing, and remitting condition in 2015. Adipose tissue deposits in organ systems are the root reason, which can have detrimental effects on health and cause dysfunction. Treating obesity like a chronic illness, like diabetes, hypertension, or coronary artery disease, is appropriate. (Glazer 2023)

Body Mass Index (BMI) is a screening tool that can determine whether a person is underweight, has a healthy weight, is overweight, or is obese. It's a calculation of *your* weight-to-height ratio and can provide insight into risk for diseases. It is applicable to both adult men and women, is a widely used and reliable anthropometric instrument for assessing an individual's nutritional and health state as well as their level of obesity (Aryal, 2020). Mathematically, it can be represented as follows:

BMI = Weight (in kg) / Height^2 (in m^2)

For more than a century, medical practitioners have used body mass index (BMI) to determine whether a person is overweight or underweight. Most medical professionals advise aiming for a BMI between 18.5 and 24.99. Before digital tools, calculating BMI was done manually using charts or tables, paper formulas, or using mechanical calculators or slide rules. These methods required users to identify the intersection of their height and weight, divide and multiply by hand, and use specific BMIs or slide rules (Brazier, 2023). The current computational approaches of measuring BMI includes: Online BMI calculator, health monitor device, Electronic health Record, automated data processing, customized algorithm and software. These methods have high accuracy and speed and are easily accessible to individual, researchers, healthcare providers. (Cervantes 2020)

Estimating a person's body fat percentage is essential for determining their level of fitness and overall health. BMI is just one measure; a more complete picture of a person's body composition can be obtained by precisely estimating their body fat percentage. This method of measuring the body fat percentage can be easily accessible and they are normally in tabular form.

BMI is a crucial statistic in medical sciences, used in various disciplines for disease diagnosis, risk evaluation, and medication dosage. It is linked to increased risks of heart disease, type 2 diabetes, hypertension, certain malignancies, and respiratory problems (Jacobs, 2023). BMI also determines eligibility for bariatric surgery and may change medication dosages based on body weight (Hristova et.al, 2023)

BMI and its relationship with body fat percentage have been predicted through the application of deep learning techniques. Megat et. al., explored the use of deep neural networks to estimate BMI from facial images. Nianogo and Arah used a supervised machine learning approach to develop and validate a prediction equation for body fat percentage obtained from Dual Energy X-ray Absorptiometry (DEXA) using measured BMI. Neeland et al., 2016, have claimed that calculating

body fat provides a more realistic picture of health and health concerns; nevertheless, obtaining a precise measurement is difficult. Methods include calipers, air displacement plethysmograph, near-infrared interactance, dual energy X-ray absorptiometry (DEXA)

This research work focuses on data processing using python programming for training task and performance evaluation

1.2 Statement of the Problem

Body Mass Index (BMI) which is a commonly used metric to evaluate an individual's body weight in relation to their height; serves as a good indicator of body fat percentage and the diseases that may be associated with higher body fat levels. In groups with excess fat-free mass, body fat percentage is a more reliable indicator of adiposity than body mass index (BMI). The risk of developing certain conditions like heart disease, high blood pressure, type 2 diabetes, gallstones, breathing issues, and some cancers is increased with a higher BMI

Deep learning can be used in addressing medical problems from high BMI. This can be beneficial in multiple ways for body mass index (BMI) such as BMI prediction, Disease Risk assessment, Image Analysis, Research and Data Analysis etc.

An essential indicator of general fitness and health is body fat percentage. It is computed using a formula that considers an individual's age, gender, height, and weight. The most widely used formula was first presented in a study paper by P. Deurenberg, main researcher, titled "Body mass index as a measure of body fatness: age- and sex-specific prediction formula," which was published in the British Journal of Nutrition in 1991.

Numerous studies have looked into the use of Feedforward Neural Networks (FNN) to predict body fat percentage based on BMI. Using BMI and sociodemographic data, Nianogo and Arah created and validated prediction equations for body fat percentage, obtaining good predictive performance and little bias in comparison to other models. With a forecast accuracy of 80.43%, Kupusinac et al. provided a program solution based on artificial neural networks (ANN) for body fat percentage prediction. When comparing several techniques, such as FNN, for estimating body fat percentage, Ferenci and Kovács discovered that support vector machines marginally outperformed both FNN and linear regression.

The Dual – energy x-ray absorptiometry (DEXA) readings used by Nianogo and Arah to create the prediction equations in this investigation might not be readily available or practical in all circumstances. This might be due to the fact that most scanning beds are too small for a typical physique of a larger person. Measuring their weight and height are more accurate and makes it easier to calculate their BMI. FNN is significant for Tabular dataset. Complex, non-linear interactions between features and target variables are frequently seen in tabular datasets as FNNs may model non-linear interactions, they may be able to better predict outcomes than linear models by capturing complex patterns in the data. FNNs, with their multiple hidden layers, can learn key features and hierarchical representations from tabular data, effectively detecting significant features and relationships among variables in high-dimensional data. They are versatile, suitable for various datasets like financial, healthcare, and customer-related ones, as they can handle structured data like numerical and categorical variables.

The development of prediction equations for body fat percentage allows for a more precise estimation of adiposity using readily accessible variables like BMI. In populations with excessive fat-free mass, body fat percentage is a more accurate measure of adiposity than BMI.

Feed-forward neural networks (FNNs) are a type of deep learning model that have been thoroughly examined in relation to over fitting and prediction accuracy. The Electronic Health Record (EHR) dataset concerning breast cancer metastasis to study of over -fitting of deep Feed-forward Neural Networks (FNNs) predicting model. The FNNs prediction model related to breast cancer metastasis was conducted using the Electronic Health Record (EHR) dataset (Xu 2022). The lack of a clear relationship between over fitting and layer count in the data suggests that this component of model architecture is not well understood.

The aim of this project is to predict Body Fat Percentage from BMI dataset using deep learning algorithm: Feed-forward Neural Network (FNN). The model will be trained which will be capable of accurately predicting Body fat percentage based on BMI, Age and Gender.

In order to create a deep learning model that predicts body fat percentage from BMI using FNNs, this offers a road map. It emphasizes the significance of accuracy, interpretability and possible applications in real life. Since FNNs can learn intricate patterns and correlations from data, this study uses them to model non-linear associations that are common in body fat percentage prediction using BMI and related characteristics.

1.3 Aim of the Study

The aim of this research is to predict Body Fat Percentage from BMI dataset using deep learning algorithm: Feed-forward Neural Network (FNN).

1.4 Specific Objectives

The objectives of this research are as follows:

- To preprocess the BMI dataset by data formatting
- To design and train an architecture of a FNN model to predict body fat percentage from BMI
- To explore and determine the most effective FNN architecture for this specific prediction task

1.5 Methodology

The BMI dataset will be downloaded from Kaggle – www.kaggle.com. The dataset will include Age, Gender, BMI.

The Keras framework of python programming is used to implement deep Feed-forward Neural Network (FNN) models for the training task and performance evaluation of Body fat percentage prediction.

Data preparation, model construction, training, and evaluation are the phases involved in building a FNN model to predict body fat percentage from BMI.

The methodology addressing the following objectives:

- To preprocess the BMI dataset by data formatting: This includes the following steps – Understanding the data (dataset identification, Preliminary data analysis), data cleaning, data structuring, data transformation, data standardization, handling missing data, structuring input and output data and data quality check (data consistency).
- To design and train an architecture of a FNN model to predict body fat percentage from BMI: This could be done using the following steps – dataset preprocessing, model architecture design, model training, model evaluation, optimization algorithm (Adam or Stochastic Gradient descent), interpretation and analysis and Iterative improvement

- To explore and determine the most effective FNN architecture for this specific prediction task: This could be done with the following approach – Data understanding and preparation, model development, hyper- parameter tuning, cross-validation and evaluation, regularization and model complexity, comparative Analysis and Final Model selection. This could help in identifying the most effective model for predicting body fat percentage.

1.6 Scope of the Study

This research is focused on predicting body fat percentage from Body Mass Index (BMI) using deep learning model - Feed-forward Neural Network (FNN). The dataset is a Tabular dataset which will include gender, age, weight, and Height and BMI value. The data preparation, design and training will be done using python programming.

1.7 Significance of the Study

The study has the potential to develop AI applications in healthcare, lead tailored health therapies, improve health assessment methodologies, and advance a more thorough knowledge of the relationship between body composition and wellness. This research gives guidance for the development and improvement of future models by offering insights into the optimization of FNN architectures for body composition assessment.

A greater understanding of a person's health status can be obtained by accurately estimating body fat percentage from BMI, which helps with personalized health recommendations and intervention. Accurate body fat measurement makes it possible to identify those who are more vulnerable to obesity-related illnesses, allowing for early intervention and preventative measures.

This gives researchers in medicine a more precise way of measuring body fat, which could lead to a better knowledge of body composition and how it affects a person's health.

1.8 Definition of Terms

- **Deep learning**: Deep learning is a machine learning and artificial intelligence technique aimed at intimidating humans and their actions based on specific brain functions for effective decision-making.

- **Deep Learning Algorithm:** Deep learning algorithm train machines by learning from example. These includes Convolutional Neural Network (CNN), Feed-forward Neural network (FNN), Recurrent Neural Networks (RNN), Long Short Memory Networks(LSTMs), Generative Adversarial Networks (GANs), Radial Basis Function Networks (RBFNs), Multilayer Perceptron (MLPs), Self-Organizing Maps (SOMs), Deep Belief Networks (DBNs), Restricts Boltzmann Machines (RBMs) etc.
- **FNN:** A feed-forward neural network (FNN) is a kind of artificial neural network in which data flows without creating loops or cycles from input nodes to output nodes via hidden layers. It is the fundamental architecture for machine learning and deep learning.
- **BMI:** Body Mass Index is a measure of body fat, indicates a higher risk of diseases like heart disease, high blood pressure, type 2 diabetes, gallstones, breathing issues, and certain cancers.

- **Body fat percentage**: this is the percentage of fat mass in relation to the total weight of the body. It shows the proportion of fat tissue to lean tissue (bones, muscles, organs, etc.) in the body.
- **Dataset:** A dataset is a digital collection of data, including images, texts, audio, videos, and numerical data points, essential for any Machine Learning project.

1.9 Organization of the thesis

This research work will be arranged as shown below:

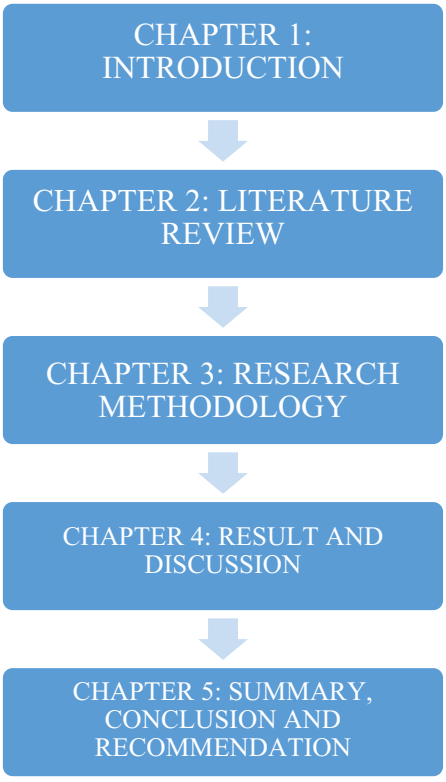

Fig.1.1: Organization of thesis

Chapter 2: Literature Review

2.1 Preamble

The connection between body fat percentage and body mass index (BMI) has drawn a lot of attention and examination in the field of health sciences in recent years. BMI, a commonly used metric based on a person's height and weight, has long been used as a convenient and rapid way to determine health risks and adiposity. But because of its shortcomings in accurately measuring body fat percentage, a lot of study has been done to determine how well it predicts adiposity.

Predicting body fat percentage based on BMI, gender and age using different neural networks has been explored in several research work. In one study, Kupusinac et al. created a computer solution that used an artificial neural network to estimate body fat percentage with an 80.43% predictive accuracy. Support vector machines marginally outperformed feed-forward neural networks, linear regression, and support vector machines in predicting body fat percentage, according to a different study by Ferenci and Kovács. When Duran et al. looked at the use of artificial neural networks (ANNs) to predict extra body fat in children, they discovered that, for males, the ANN approach outperformed body mass index and waist circumference, but for girls, the ANN and BMI performed similarly. Furthermore, Kupusinac et al. used to examine the connection between BMI and body fat percentage.

2.2 Theoretical Framework

The core theories, concepts, and models that support the relationship between BMI and body fat are established in the theoretical framework for a literature evaluation on predicting body fat percentage from BMI. In a study conducted by Paul Deurenberg and his colleagues, the BMI, percentage body fat, gender, and age of American Blacks, Caucasians, Chinese, Ethiopians, Indonesians, Polynesians, and Thais were examined. They discovered that the BMI and percentage of body fat varied among the ethnic groups (Deurenberg, 1998).

2.2.1 Biological and Physiological Theories

Body mass index (BMI) can be used to predict body fat percentage using biological and physiological hypotheses. Regression equations generated from a physiological model of body

composition are one method; these equations presume that obese patients can be represented by an extra weight with constant fractions of muscle, bone, and adipose, plus a lean reference subject (Levitt et. al., 2012). An alternative method entails adjusting the conventional BMI calculation to take into consideration differences in body proportions and lean-to-fat ratios, especially in tall and short people and athletes (Haute et. al., 2020). Additionally, prediction equations for Body fat Percentage (BF%) based on BMI and sociodemographic variables have been created using supervised machine learning approaches (Nianogo 2023). Additionally, it has been demonstrated that adding relative handgrip strength measurements to BMI-based models improves prediction accuracy (Nikerson 2020). In another research, BF% has been predicted using artificial neural networks based on gender, age, and BMI, offering a greater predictive accuracy than conventional methods (Alexsandar 2014)

2.2.2 Health Assessment Frameworks, Medicine and Public Health perspectives

Although body mass index (BMI) is frequently used to evaluate obesity, it is not a very reliable indicator of body fat percentage. Numerous research works have investigated the relationship between BMI and percentage of body fat. Trefethen suggested a revised BMI calculation that accounts for individual variations in body proportions (Haute 2020). A link between body fat % and BMI was discovered in another investigation, indicating that BMI is a reliable predictor of fat percentage (Nair (2017). With more prediction accuracy than conventional formulas, artificial neural network (ANN) models have been constructed to forecast body fat percentage based on BMI, age, and gender (Alexsandar 2014). It is crucial to remember that BMI does not accurately reflect a person's body composition because it does not distinguish between muscle and fat mass and does not take into consideration characteristics like age, gender, ethnicity, or level of physical fitness (Lukaski 2014). Although body fat percentage has been predicted using soft computing techniques like support vector machines, its effectiveness is still restricted (Ferenci 2014).

2.2.3 Statistical and Predictive Modeling Theories

Despite its widespread use, body mass index (BMI) is not a very good indicator of body fat percentage (BF%) in people with high levels of fat-free mass. The goal of several studies has been to create BF% prediction models utilizing BMI and other sociodemographic variables. Using BMI, age, gender, education, income, and interaction terms, Nianogo and Arah created prediction

equations that demonstrated excellent predictive power and minimal bias. Using BMI and sex, Itani et al. created a simplified prediction equation that correctly predicted BF% in people who were overweight or obese with non-significant prediction bias (Nianogo 2023). Age, BMI, anthropometric measurements, and skinfold measurements were all included in the statistical regression models that Merrill et al. created. These models predicted BF% with average errors of less than 0.10% (Itani et. al., 2020). These studies demonstrate how crucial it is to take into account variables other than BMI when predicting BF% and offer insightful information about how to create precise models for estimating BF% in various populations.

2.3 Review of relevant literature

This section includes research work that are applicable to this thesis; their aim and objectives, and methodology and limitations. According to Kupusinac et al, their paper aims to present a program solution based on Artificial Neural Networks (ANN) for body fat percentage (BF%) prediction using body mass index (BMI), age (AGE), and gender (GEN) as inputs. The main objective is to advance a novel method of BF% prediction that is more predictively accurate while maintaining the same level of complexity and expense as current formulas. In order to predict BF% based on GEN, AGE, and BMI, the paper compares the predictive accuracy of the ANN solution with other broadly applicable formulas. The study's scope was restricted to Serbian citizens, and various ethnic groups may have distinct relationships between body fat (BF) and BMI. The dataset employed in the study, which included 2755 participants, could not be entirely representative of the community. Although 80.43% was stated to be the artificial neural network (ANN) solution's predicted accuracy, it is unclear how this accuracy was calculated or verified. In the validation phase, the methodology entailed examining single hidden layer ANN topologies with different numbers of hidden neurons to identify the architecture with the lowest mean square error; 31 hidden neurons were found to be the ideal number.

Models were developed using a supervised machine learning approach and were validated using data from National Health and Nutrition Examination Survey (NHANES) in the U.S. A research work done by Nianogo’s team aimed at developing and to validate prediction equations for BF% using BMI and socio-demographic factors. The study's particular objectives were to: Create prediction models based on age, gender, education, income, and interaction factors using a supervised machine learning technique. Utilize data from the US National Health and Nutrition

Examination Survey (NHANES) to validate the created models. Examine how well the developed models perform in comparison to other published models. Using the best model, determine the degree of bias in the relationship between high low-density lipoprotein (LDL) and anticipated body fat percentage. Analyze the developed models' usability and simplicity in low-resource environments. Data from the National Health and Nutrition Examination Survey (NHANES) (which included 5931 and 2340 persons aged 20 to 69, respectively) from 1999–2002 and 2003–2006 were used in the study. In particular, ordinary least squares were utilized in a supervised machine learning approach to create prediction equations for BF%. Variables including age, gender, education level, income, and interaction terms were used to create the models. Based on the models' R-squared values and root mean square error, they were assessed and chosen. The created models' performance was contrasted with that of other published models. Next, the degree of bias in the relationship between high low-density lipoprotein (LDL) and anticipated body fat percentage was evaluated using the best models. The simplicity and convenience of use of the developed models in low-resource settings were also evaluated.

Ferenci and Kovacs used data from a sample US health survey of adult males, linear regression, feedforward neural networks, and support vector machines are employed to examine how well body fat % can be predicted from easily measurable data. Their research aims to propose a programme solution based on artificial neural networks (ANN) for body fat percentage (BF%) prediction using body mass index (BMI), age (AGE), and gender (GEN) as inputs. The major objective is to promote a novel method of BF% prediction that is more accurate but has the same complexity and expenses as current formulae. In order to forecast BF% based on GEN, AGE, and BMI, the research compares the predictive accuracy of the ANN solution with other broadly applicable methods. The research utilized a feed-forward artificial neural network (ANN) with back-propagation as its training algorithm. The optimal architecture consisted of a single hidden layered structure with 31 hidden neurons. Body mass index (BMI), age (AGE), and gender (GEN) were the inputs used in the ANN, while body fat percentage (BF%) was the output. For the investigation and outcome comparison, MATLAB software, namely Version 7.11.0.584 (R2010b), was used.

Itani et al. created a straightforward BF% prediction equation utilizing sex and BMI that correctly predicted BF% in people who were overweight or obese. The aim of the research was to create a

user-friendly predictive formula for calculating body fat percentage (BF%) in overweight and obese Lebanese individuals based on body mass index (BMI). The objective was to develop a simplified prediction equation that, when combined with anthropometric data, could reliably estimate the BF% in this population. By comparing the measured and predicted BF% in a validation sample of subjects, the study sought to assess the prediction equation's validity. Additionally, the researchers sought to evaluate prediction bias and ascertain the association between the measured and anticipated BF%. Furthermore, the study sought to develop gender-specific prediction equations for BF% estimate in overweight and obese people in a clinical context in Lebanon.

L.N. Trefethen, a professor of numerical analysis of University of Oxford in his article he wrote in 2013 titled “Body Mass Index” stated that “the current BMI formula seems to underestimate obesity in shorter people and overestimate obesity in taller people, thus, he suggested a new formula : BMI = 1.3 X Weight (Kg)/ height (m) 2.5. A study done by Haute and team examines how well a modified version of L. N. Trefethen's BMI formula performs in comparison to the conventional formula for estimating body fat percentage (%BF) and identifying overweight/obesity in young individuals from the Philippines. Using the best BMI cutoff values, both algorithms correctly distinguished between normal and overweight-obese states and significantly predicted %BF. The study was conducted among a sample of Filipino young adults (n=190) to assess the performance of the modified BMI formula against the traditional one in predicting body fat percentage (BF %) measured using bioelectric impedance analysis and diagnosing overweight/ obesity.

A correlation between BMI and BF % was found and it found that BMI is a fair indicator to assess fat percentage. This research was conducted by Nair in a journal of medical science and clinical research. The aim of his research was to evaluate the relationship between body fat percentage and body mass index (BMI). The objective was to ascertain whether BMI is a reliable indicator of body fat percentage. Male adult participants in the study, ages 35 to 45, appeared healthy and had no visible systemic illness. The subjects' weight and height were determined on an SECA balance. The formula for calculating BMI was BMI = Weight (kg) / Height^2 (m^2). BMI was used to categorize the study group into three groups: Group I (BMI < 25), Group II (BMI 25-29.9), and Group III (BMI > 30). The Archimedean principle-based technique of hydro densitometry was used to determine the fat percentage. The body density of the participants was determined by

measuring the displacement of water after they were submerged in it. The percentage of fat and fat-free mass was computed using this information. Analysis of Cluster Variability (ANOCVA), the Kruskal-Wallis test, and other statistical techniques were used to examine the relationship between BMI and fat percentage.

Pre-trained Convolutional Neural Networks (CNNs) have formed the basis of deep learning models that are used to predict Body Mass Index (BMI) using facial picture data. The accuracy with which these algorithms have been able to predict BMI scores and classes is encouraging. It has been discovered that using deep pre-trained CNN models, as opposed to more conventional techniques like the Adaboost algorithm or the Haar classifier, improves accuracy and decreases computing time. This research was conducted by Megat et.al. The aim of the paper was to predict Body Mass Index (BMI) scores and BMI classes from detected face images using pre- trained CNN models. The objective was to evaluate the effectiveness of deep pre-trained CNN models in predicting body mass index (BMI) and to compare them with conventional techniques like the Adaboost algorithm and the Haar classifier. Evaluating the MTCNN algorithm's efficacy for face detection and cropping during the image pre-processing phase of BMI prediction is another goal.The purpose of the study was to shed light on the pre-trained CNN models' accuracy and computation time in comparison to conventional techniques, emphasizing the benefits of applying deep learning techniques for BMI prediction. In order to estimate BMI from face photos, this paper's methodology combines deep pre-trained CNN models developed using the Keras framework with the MTCNN algorithm for face detection and cropping.

The majority of the single hyper-parameters are either adversely or favorably adjusted with model prediction performance and over fitting, according to Xu 2022 and his team, who employed an EHR dataset pertaining to breast cancer metastasis to investigate over fitting of deep feed-forward neural networks (FNNs) prediction models. Examining overfitting in deep feedforward neural networks' (FNNs) prediction models for breast cancer metastasis was the study's aim. The objective is to investigate the effects of each of the deep FNNs models' eleven hyperparameters, given a wide range of values, on prediction performance and overfitting. Analysing the relationships between specific pairs of hyperparameters and how they affect overfitting and model performance is another goal. The goal of the study was to determine which hyperparameters—such as learning rate, decay, and batch size—have a major influence on overfitting and prediction performance. The project also intends to test current machine learning expertise and offer fresh

research that may help reduce overfitting during grid search and hyperparameter tuning.Additionally, the study seeks to shed light on how hyperparameters relate to the range of meantrainAUC, meanestAUC, and percentAUCdiff—metrics that are employed to assess overfitting and model performance.

Multiethnic Dallas Heart Study (DHS) cohort, assessments of visceral adipose tissue (VAT) mass was compared using dual X-ray absorptiometry (DXA) and magnetic resonance imaging (MRI) (DHS) (Neeland et. al. 2016). The objective of the study was to determine the validity and reliability of DXA as a workable substitute for MRI in the clinical context, as well as the correlation and agreement between DXA and MRI assessments of VAT mass. The study also sought to evaluate the consistency of results across several subgroups based on sex, race, body mass index status, waist circumference, and body fat. It also sought to ascertain the inter-reader variability of DXA measures. The researchers also sought to ascertain the DXA method of VAT quantification's potential utility for clinical and research applications, as well as to validate it against MRI as the gold standard. In this investigation, a sizable multiethnic cohort of Dallas Heart investigation (DHS) participants had paired measurements of their visceral adipose tissue (VAT) using dual-x-ray absorptiometry (DXA) and magnetic resonance imaging (MRI). Using a Discovery W DXA scanner, the VAT mass measurements were made, and APEX software version 13.4.2 was used for analysis. The DXA technique involved estimating VAT from the total amount of measured abdominal fat by using the lateral abdominal subcutaneous adipose tissue (SAT) seen in the DXA image to determine the anterior and posterior abdominal SAT. The MRI VAT mass data, which were represented as total mass covering the L1-L5 area [1], were then compared to the DXA VAT mass data. The correlation between DXA and MRI readings was assessed using regression analysis, and bootstrapping was used to validate the model. A randomly chosen group of scans was used to analyze inter-individual reader correlation as well as inter-reader variability of DXA values. The findings were examined and categorized according to sex, race, waist circumference, body fat percentage, and body mass index to determine how consistently the results applied to various subgroups.

2.5 Summary/meta-analysis of Reviewed of Related Works

Deep learning Model have attracted interest for their direct prediction of Body Fat Percentage from BMI, however there may not be a large body of literature dedicated to this method. Nonetheless, the use of neural networks such as ANN, CNN and FNNs—for studies pertaining to BMI and

health-related forecasts has been developing. The Summary of the reviewed related work is shown in the Table 2.1 below:

Table 2.1: A summary of the related studies reviewed

S/N	AUTHOR/ YEAR	TITLE	BRIEF EXPLANATION	AIM & OBJECTIVES	METHODOLOGY	LIMITATIONS
1	Kupusinac et. al 2014	Predicting Body Fat Percentage based on gender, age and BMI by using artificial neural networks	The study describes a program that uses an artificial neural network (ANN) to forecast body fat percentage (BF%) based on gender (GEN), age (AGE), and body mass index (BMI).	The research proposes an artificial neural network (ANN)-based program for predicting body fat percentage using BMI, age, and gender inputs, aiming to improve accuracy while reducing complexity and expenses compared to current formulae.	The study used a feed-forward artificial neural network (ANN) with back-propagation as the training technique. The optimal configuration of the network was found to be a single hidden layered architecture with 31 hidden neurones. Body fat percentage was the result, and the inputs were gender, age, and BMI. The data were analysed and compared using the MATLAB software.	The study, limited to Serbian citizens, may not accurately represent the community due to the ethnic differences in body fat and BMI relationships. The 2755 participant dataset may not be representative, and the accuracy of the artificial neural network is unclear.

The study's specific objectives were to: Create a new body fat equation (BMINICKERSON) that includes RHG as a variable and is based on BMI. Cross-validate BMINICKERSON against a four-compartment criterion, as well as the current	handgrip strength into account was created and cross-validated. A four-compartment regression analysis and a four-compartment model were used to calculate the equation. In comparison to other BMI-based equations, BMINICKERSON has reduced constant error and total error values, according to the cross-validation data. Additionally, compared to earlier equations, the 95% limits of agreement for BMINICKERSON were smaller, suggesting increased accuracy. The study found that while taking RHG into account helps	validated a novel body fat equation based on BMI. It did not, however, take other elements or variables influencing body fat measurement into account. Only individuals of Hispanic or non-Hispanic White ethnicity were included in the study; there were 110 participants in the cross-validation sample and 230 participants in the development sample. The body fat percentage was calculated using the four-compartment model; alternative

				BMI-based body fat equations (BMIWOMERSLEY, BMIJACKSON, BMIDEURENBERG, and BMIGALLAGHER).	enhance the prior BMI-based body fat equations, they still create significant inaccuracies.	techniques for assessing body composition were not taken into account. The novel body fat equation based on BMI was not compared to any other current equations or methodologies in the study.
10	Nair 2017	Relationship between Body Mass Index and Body Fat percentage	This research intends to evaluate the relationship in adult males between BMI and body fat percentage. Male adult participants in the study ranged in age from 35 to 45. The formula used to determine BMI was BMI = Weight (kg) / Height^2 (m^2).	The aim of the research was to evaluate the relationship between body fat percentage and body mass index (BMI). The objective was to ascertain whether BMI is a trustworthy measure of body fat percentage.	A study on healthy adult males aged 35-45 found a significant correlation between BMI and fat percentage. The subjects were divided into three groups based on BMI, and fat percentage was assessed using hydrodensitometry. Statistical methods like ANOCVA, Kruskal-Wallis test, and correlation	The submersion method for measuring body volume may not be accurate for obese individuals due to its reliance on active participation and the assumption of a fixed value for air and gas in the stomach and intestinal tract. The study's generalizability may be limited to a specific group.

					analysis were used to analyze the data. The findings suggest that BMI is a reliable assessment of fat content in adult males.	

2.5.1 Research gap identified in related work

One of the gap observed in the reviewed related work as shown in Table 2.1 on predicting body fat percentage from BMI is the limited exploration of Feed forward Neural Networks (FNNs) despite the fact that many previous studies have investigated neural networks for health –related predictions.

This project focuses on predicting Body Fat Percentage from BMI dataset using deep learning algorithm: Feed-forward Neural Network (FNN). The model will be trained which will be capable of accurately predicting Body fat percentage based on BMI, Age and Gender. Exploring and determining the best FNN architecture for this particular prediction problem will be done

Chapter 3: Research Methodology

3.1 Preamble

In order to analyze the relationship between body fat percentage and body mass index (BMI), this study used a systematic research approach based on deep learning techniques. Feed-forward Neural Networks (FNNs) enable a more in-depth analysis of the predictive power of body fat percentage estimation from BMI. This section describes the comprehensive approach used to collect, preprocess, and analyze data in order to guarantee the authenticity and dependability of the study's findings.

3.2 Problem formulation

The problem formulation process for Feedforward Neural Networks (FNNs), which aim to predict body fat percentage from Body Mass Index (BMI), entails a comprehensive methodology and systematic approach. This methodology is selected to encompass the qualitative comprehension of the detailed correlation between body fat percentage and BMI, as well as the quantitative patterns obtained by deep learning models.

Deep learning can be applied to medical issues resulting from elevated body mass index. Body mass index (BMI) can benefit from this in a number of ways, including BMI prediction, disease risk assessment, image analysis, research, and data analysis, among others.

The application of feedforward neural networks (FNN) to estimate body fat percentage based on BMI has been the subject of numerous studies. Nianogo and Arah developed and validated prediction equations for body fat percentage using sociodemographic and BMI data, getting strong predictive performance and negligible bias in contrast to other models. With a forecast accuracy of 80.43%, Kupusinac et al. offered a programme solution based on artificial neural networks (ANN) for body fat percentage prediction. Support vector machines slightly outperformed both FNN and linear regression when Ferenci and Kovács compared multiple methods, including FNN, for determining body fat percentage.

This project focuses on predicting Body Fat Percentage from BMI dataset using deep learning algorithm: Feed-forward Neural Network (FNN). The model will be trained which will be capable of accurately predicting Body fat percentage based on BMI, Age and Gender. FNN Architectures will be explored to determine the most effective for this specific prediction task.

3.3 Approach and Technique(s) for the proposed solution

The proposed approach for employing feed forward neural networks (FNNs) to estimate body fat percentage from BMI entails applying a number of strategies in a systematic manner. The goal of the proposed approaches and methodology is to create a specialized FNN model that can accurately estimate body fat percentage from BMI. Because the process is iterative, it is possible to continuously refine it based on insights gained during the creation and evaluation stages of the model's performance. The techniques and approaches involves the design of framework, Formulation of model, Development of algorithm and development of scheme.

3.3.1 Proposed Solution:

The proposed solution framework related to this research objective is described below:

I. Data processing:

- Transform the BMI dataset such that it may be used in a structured model training approach.
- Ensure that the data types are consistent and deal with any inconsistencies in the dataset.

II. Feature Engineering:

- Feature Extraction: Extract relevant variables like age, gender, and BMI from the BMI dataset.
- Feature Scaling: To enhance the convergence of the model, normalize numerical features to a similar scale.

III. Model Development:

- FNN Architecture Design:
  - Create different FNN model designs by adjusting the layers, neurons, and activation functions.
  - Explore a variety of architectures to show the complex relationships between body fat % and BMI.
- Training:
  - Split the preprocessed dataset into sets for validation and training.
  - Train all FNN model architectures using the relevant algorithms for optimization and hyperparameters on the training set.

- Evaluation: Evaluate the performance of each trained model on the validation set using evaluation metrics: Mean Absolute Error (MAE).

IV. Exploration of Effective FNN Architecture:

- Model Comparison:
  - Based on evaluation metrics, compare the effectiveness of various FNN designs.
  - Determine which architecture predicts body fat % from BMI with the lowest error and maximum accuracy.
- Hyperparameter Tuning:
  - To further optimize model performance, tune the hyperparameters of the selected FNN architecture.
- Model Interpretability:
  - Analyse the selected FNN architecture in order to comprehend how predictions are made.
  - To understand the connection between BMI and body fat %, interpret the learnt weights and biases.

V. Iterative Improvement:

- Refinement: Fine-tune the selected FNN architecture in relation to the knowledge gathered from the interpretation and analysis of the model.
- Validation: Validate the improved model's ability to be generalized using data that hasn't been seen before.

VI. Documentation and Reporting:

- Record every step of the process: the data preprocessing stages, the FNN architecture designs, the training methods, and the evaluation outcomes.
- Write a thorough report that summarizes the research's conclusions and learnings.

3.3.2 Design of framework

The framework design for predicting body fat percentage from BMI using a Deep learning model, specifically FNN includes the framework design, workflow procedures and the project considerations. The framework design is illustrated in the figure below. This Illustration represents the various components and steps involved in the framework design. Each component has a crucial role in accomplishing the research objective and adds to the process of developing, analyzing, and documenting models. The workflow procedures, data processing techniques and the project considerations are also briefly discussed in the tables below:

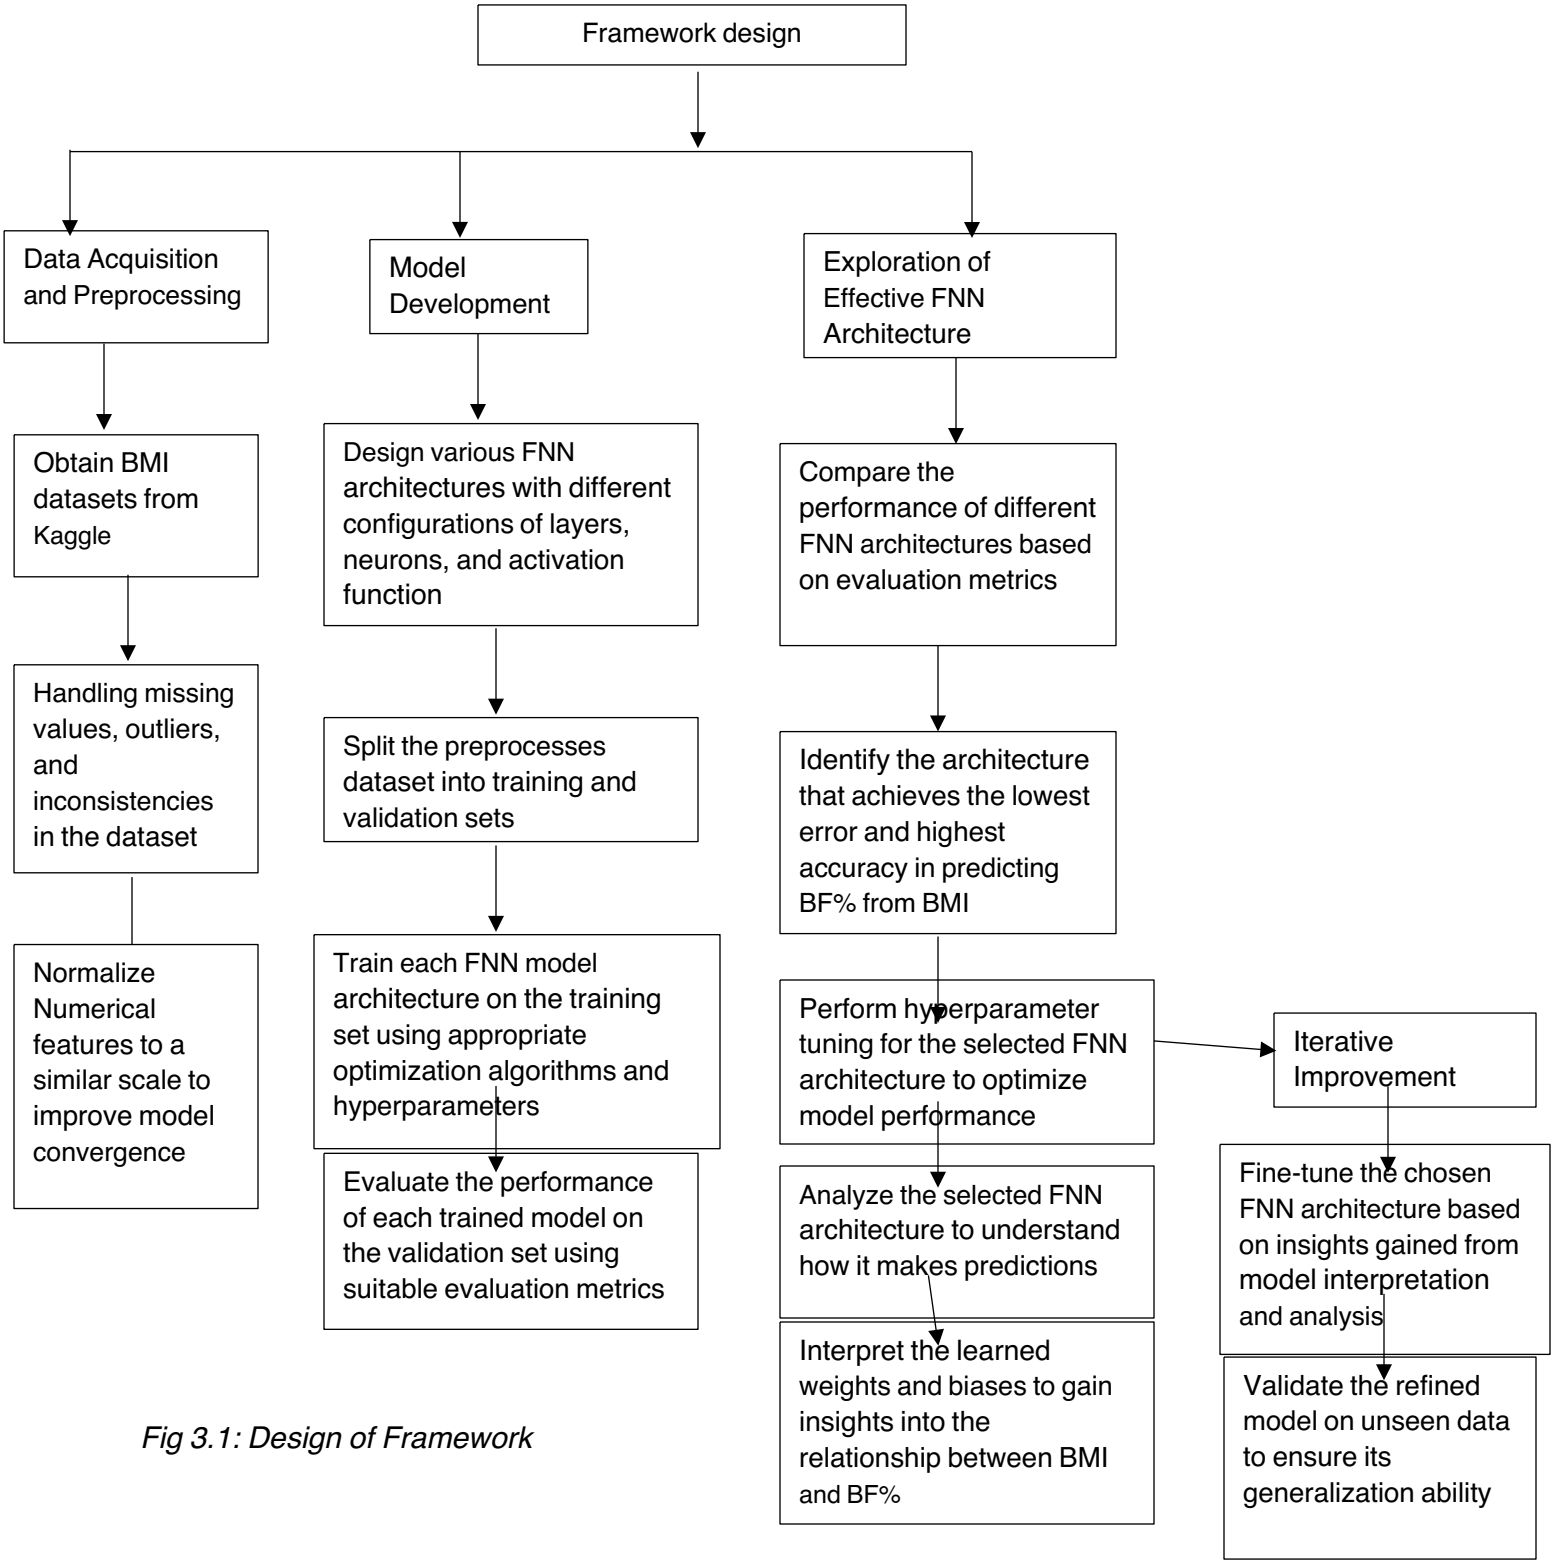

Fig 3.1: Design of Framework

Table 3.1: Workflow procedures

WORKFLOW	PROCEDURES
Initialization	Load the necessary modules and libraries. Initialize the data, model, and training objects.
Data Processing	Data collection Data cleaning Feature Engineering Data Normalization Data Splitting Data Augmentation Final Dataset preparation
Model Configuration	Use the Model Module to set the hyper parameters and configure the FNN model.
Training	With the option to modify the hyperparameters, train the model using the Training Module.
Evaluation	Apply the Evaluation Module to assess the model's performance and interpret predictions.
Experimentation	Utilizing the Experimentation Module, run tests with various model configurations.
Documentation	Use the Documentation Module to automatically create documentation for models, experiments, and research in general.

Table 3.2: Data Processing Techniques:

S/N	DATA PROCESSING TECHNIQUES	PROCEDURES
1	Handling Missing values	In order to guarantee that the dataset is full, handle any missing BMI values using the proper imputation techniques, such as mean, median, or mode replacement.
2	Scaling Numerical Features	Apply techniques such as Z-score normalization or Min-Max scaling to bring the BMI values into a comparable range. This can speed up the neural network's convergence during training by guaranteeing that all numerical features are on a similar size.
3	Encoding Categorical Variables	Before putting the input into the neural network, convert the categorical variable (gender) into numerical representation using one-hot encoding or label encoding approaches.
4	Feature Engineering	To give the FNN more information, consider adding a feature like age. Feature engineering can assist in capturing intricate correlations between variables and enhance the model's capacity for prediction.
5	Data Splitting	Split the dataset into sets for training and validation in order to assess the FNN's performance. In order to evaluate the model's capacity for generalization, this guarantees that it is trained on one set of data and evaluated on another.

Table 3.3: Project Considerations:

CONSIDERATIONS	REQUIREMENTS
Modularity and Extensibility	Every module have to be designed to operate autonomously, facilitating effortless modifications or substitutions of particular components.
Configurability	For experimentation adaptability, parameters, hyper parameters, and experimental settings should be readily adjustable.
Scalability	Scalability in terms of computational resources should be possible for the framework, which can manage datasets of different sizes.
Usability	To make it easier for researchers and practitioners to use, provide clear interfaces and documentation.
Reproducibility	Put in place repeatability measures, such as experiment logging and random seed control.

3.3.3 Formulation of model

Using a deep learning model such as the feedforward neural network (FNN), you may create a predictive model that uses BMI to estimate body fat percentage. To do this, you must describe input features, define the neural network's architecture, and set up the training procedure.

Below is an illustration of the FNN architecture for predicting body fat percentage from BMI

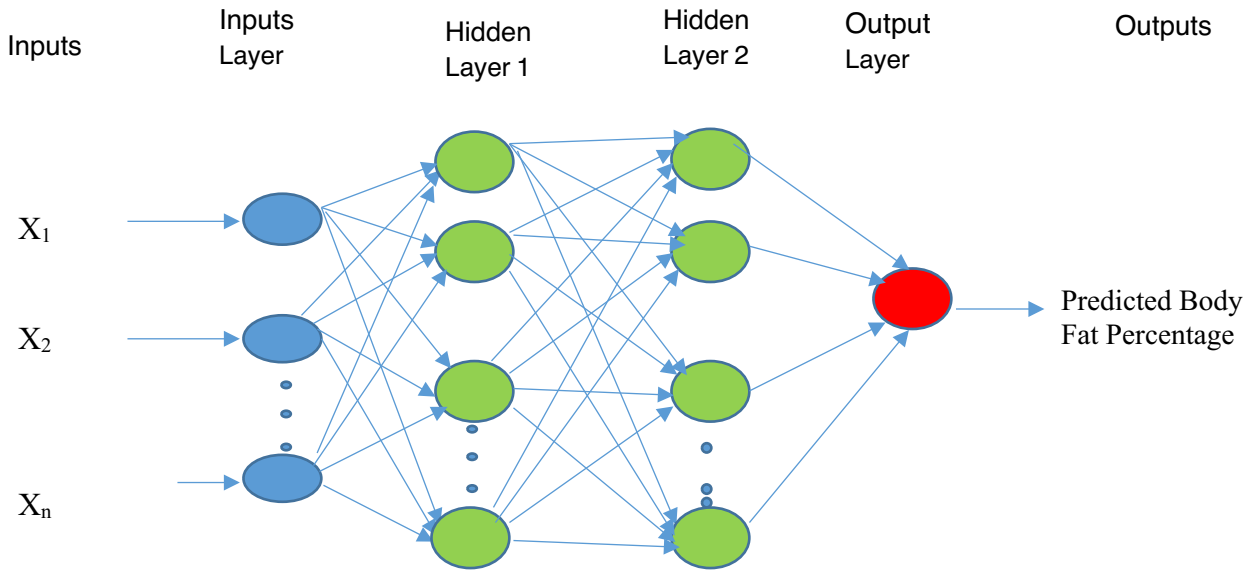

Fig 3.2: FNN Architecture

3.3.3.1 Feedforward Neural Network (FNN) Architecture:

I. Input Layer:

- Neurons: 3 Neurons (Age, Gender, BMI)
- Activation Function : Identity Function
- Description: The input layer is where the features of the input data - BMI, Age and Gender are received. There is no activation function used in this layer, and each neuron correlates to a single characteristic.

II. Hidden Layer:

- No. of Hidden layer: 2 layers
- Neurons: The 1st hidden layer has 32 neurons, The 2nd layer has 16 neurons
- Activation Function: Rectified linear unit (ReLU)
- Description: By extracting and transforming features from the data, the hidden layers are able to identify intricate patterns. Experimentation is required to fine-tune the hyperparameter of the number of hidden layers and neurons in each layer. Because ReLU and its derivatives operate well in deep neural networks, they are frequently utilized as activation functions in hidden layers.

III. Output Layer:

- Neurons: 1 neuron (predicting body fat percentage)
- Activation Function: Linear activation function
- Description: The estimated body fat % is the result of the output layer's final projection. Given that this is a regression task, the output neuron generates continuous output values using a linear activation function, also known as the identity function.

3.3.3.2 Input Features:

- BMI: The body mass index as a numerical attribute
- Age: The age of adults ranging from 18 to 65 serves as the numerical attribute
- Gender: Encode as numerical attributes (0 for male, 1 for female)

3.3.3.3 Model Formulation:

I. Loss Function:

- For regression tasks, Mean Squared Error (MSE) is used as loss function. The formula is as thus:

  $\frac{1}{N}\sum_{i=1}^{N}\left(y_i-\hat{y}_i\right)^2$

  Where; N = number of samples,

  y_i = true body fat percentage

  $\hat{y}_i$ = predicted body fat percentage

II. **Optimization Algorithm**: To reduce the loss during training, Stochastic Gradient Descent (SDG) will be used. This will be effective for training FNNs on a medium dataset

III. Training Process:

- Dataset will be split into training and validation sets.
- Input feature will be Normalized to accelerate convergence
- Training set will be used to train the FNN and validation set for validating
- During training, monitor performance metrics (MSE)
- To prevent over fitting, implement early stopping.

3.3.3.4 Hyper-parameters:

- **Learning Rate (lr):** The step size at which the neural network parameters are updated during training is determined by the learning rate. It is an important hyperparameter that influences the training process's convergence and stability. It is important to carefully adjust the learning rate to strike a balance between stability and quick convergence. While 0.001 to 0.01 are common starting numbers for learning rates, the dataset and network architecture may have an impact on the ideal value.

- **Number of Hidden Layers and Neurons**: Another important factor is the FNN's architecture, which includes the quantity of neurons and hidden layers in each layer. The complexity of the dataset and the problem should be taken into consideration while determining the number of hidden layers and neurons. Under fitting can occur by having too few neurons or layers, whereas over fitting can occur from having too many.

- **Activation Functions:** The performance of the model can be greatly impacted by the selection of activation functions for the FNN's hidden layers. Tanh, sigmoid, and ReLU (Rectified Linear Unit) are examples of common activation functions. In this research we will try these activation functions and select the one that yields the best performance in terms of accuracy and convergence speed.

- **Batch Size:** The batch size determines the number of samples used in each iteration of training. The default batch size for this research is 32. Other values can be used if not satisfied with the default value.

- **Number of Epochs:** The amount of times the model sees the complete dataset during training depends on the number of epochs. The training loss's convergence behaviour on a validation set needs to be taken into consideration while determining the number of epochs. It is crucial to keep an eye on the loss

curves for training and validation, and to cease training as soon as the validation loss begins to rise (a sign of overfitting).

3.3.4 Development of algorithm

This involves specifying the step-by-step instructions for data processing, model formulation, training, and evaluation. Below is a high-level algorithm for this task:

3.3.4.1 Algorithm for Predicting Body Fat Percentage from BMI using FNN:

I. Input:

- Dataset: This contains samples with features: Age, Gender, BMI and corresponding Body fat percentages

II. Data Preprocessing:

- Load Data: Load dataset into memory
- Features and Labels: Split up Features (input) and Labels (Body Fat Percentage) from the dataset.
- Normalization: Standardize numerical features to ensure compactible scales.

III. Model Formulation:

- Define FNN Architecture: Describe details about the input layer, hidden layers, and output layer of the FNN model's architecture.
- Compile Model: Select the optimization Algorithm (Adam) and loss function (Mean Squared Error for regression). Then, compile the model.

IV. Training:

- Split Dataset: Dataset is split into training and validation sets.
- Training Loop: For each epoch:
    - Provide the FNN model with the training data,
    - Reduce the loss, using the optimization algorithm to update the model's parameters.
    - Throughout training, observe both validation and training loss.
- Early Stopping: If validation loss stops getting better, use early stopping to terminate training.

V. Evaluation:

- Evaluation Model: Make predictions on the validation set using the trained model, Utilize measures like Mean Absolute Error (MAE) or Mean Squared Error (MSE) to assess the model's performance.

VI. **Prediction:** Make predictions using the trained model on fresh or unobserved data.

VII. **Interpretability:** implement interpretability techniques such as saliency maps to understand how the model makes predictions.

VIII. **Results:** the following procedures are done when reporting results:

- Document the performance metrics of the model.
- Visualize predictions against true values

3.3.5 Development of Scheme

Scheme development involves creating a visual representation of the procedures involved in predicting body fat percentage from BMI using FNN. The schematic representation of this process can be shown below:

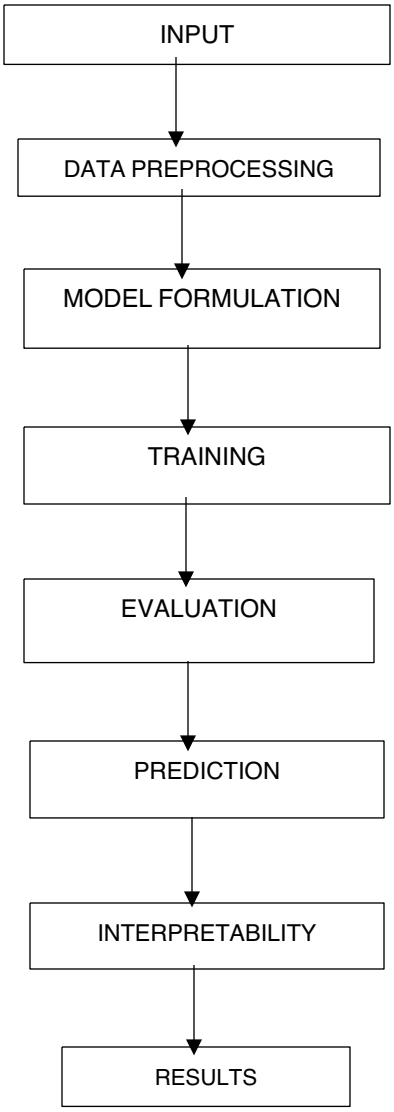

Fig 3.3: Development of Scheme

3.4 Proposed technique/ approaches

This proposed approach builds a customized FNN model for body fat percentage prediction from BMI by utilizing cutting-edge deep learning algorithms, optimization strategies, and interpretable components. The proposed, Approaches and Techniques are briefed as follows:

3.4.1 Approaches:

The approaches below are used with respect to the objectives of this research:

I. Preprocessing Approach:

One of the objectives of this research is to preprocess BMI data in the context of predicting body fat percentage from BMI using FNN involve the following steps:

- **Data Cleaning:** To guarantee that the BMI data is accurate and consistent, perform data cleansing. This could entail cleaning out any duplicate entries, fixing errors, and organizing the BMI value format.
- **Handling Missing Values**: This is done by Finding and addressing any missing values in the BMI information. The mean imputation approach was chosen to impute missing BMI values
- **Outlier Detection and Treatment**: this is done by finding and dealing with anomalies in the BMI information. Outliers have the potential to distort the distribution and impair the model's functionality. The Interquartile Range (IQR) technique was applied to detect outliers because does not rely on the assumption of normalcy and is resistant to outliers.
- **Scaling or Normalization:** this will ensure that the features in BMI data have a similar scale. For improving the convergence and performance of the FNN model, the standardization scaling was chosen since the data doesn't contain outlier.
- **Feature Engineering**: To derive additional features from BMI data that may enhance the predictive power of the model, an interaction term between BMI and gender will be created.
- **Data Splitting:** the preprocessed data will be split into training, validation and tests sets. The training set is used to train the FNN model , the validation set is used to tune hyperparameters and monitor model performance, and the test set is used to evaluate the final performance

II. Design and training an architecture of Feed-forward Neural Network

The approach used to design and train an architecture of FNN model to predict body fat percentage from BMI involves the following steps:

- **Data processing**: this prepares the dataset by handling missing values and outliers. The dataset is split into training , validation and test sets
- **Feature Engineering:** the relevant features and target variable such as BMI and BF% are selected

- **Model Architecture Design**: the FNN model contains the input, hidden and output layers. The input layers has 3 neurons, the hidden layers are 2 and each layers has 32 and 16 neurons respectively with ReLU activation function. The output layer has a single neuron.
- **Model Compilation**: the FNN model is compiled by the Mean Square Error loss function for regression task, optimizer and Adam Optimizer
- **Model Training**: this is using model fitting; model.fit() for data iterations and validation
- **Model Evaluation**: evaluate the trained FNN model on the test set. The Mean Square Error will be used to quantify the model's accuracy and reliability
- **Model Interpretation**: Interpret the trained FNN model to gain insights into the relationships between the input feature (BMI) and target variable (BF %). Also, visualize the model and comparing them with actual values to identify any patterns.

III. Exploring and determining the most effective Feed-forward Neural Network Architecture

To explore and determine the most effective FNN architecture for predicting BF % from BMI involves an iterative process of experimentation and evaluation. The following approaches were followed:

- Identifying FNN architectures and techniques used in related studies and their performance in predicting BF % from BMI. This include research work done by Nianogo and Arah used a supervised machine learning approach to develop and validate a prediction equation for body fat percentage obtained from Dual Energy X-ray Absorptiometry (DEXA) using measured BMI, Megat et. al., explored the use of deep neural networks to estimate BMI from facial images etc.
- **Model Selection:** a simple architecture with one hidden layer can serve as a starting point. This will serve as a baseline model to establish a performance benchmark
- **Hyper-parameter Tuning:** during the hyper tuning process; Input layer = 3 neurons, Hidden layer = 2 (32 and 16 neurons respectively), Activation function = ReLU, Batch size = 32, Enoch = 50. The hyper tuning method for this research is the random search because it is efficient for large or continuous spaces.
- **Cross Validation:** the K-fold cross-validation will be used to access the generalization performance of different FNN architecture. The dataset will be split into training,

validation and test sets and the performance of each architecture on multiple folds of the training data will be evaluated.

- **Model Evaluation Metrics:** Mean Squared Error (MSE) for this regression task is chosen for this research
- Experimentation and Comparison: Training and evaluating each architecture using MSE to compare their performance.
- **Iterate and Refine:** Analyzing MSE obtained from evaluating different model architectures on the validation set, identify strengths and weaknesses of each architectural variation based on their performance metrics, adjust the hyperparameters of the FNN model and refine architectural choices of the FNN model based on the observed performance.
- **Validate on Test Set:** Validate the performance of a potential FNN architecture that was found by using a hold-out test set that wasn't utilized during the experimentation phase. This offers an impartial approximation of the model's capacity for generalization.
- **Document Findings:** document the findings from the architectural exploration process

3.4.2 Techniques

The techniques which are applicable to predicting body fat percentage from BMI using FNNs are the Batch Normalization and Data Augmentation.

I. Batch Normalization:

This technique normalizes the activations of each layer to stabilize training and accelerate convergence. While training FNN model, it helps to improve its stability and hasten its convergence during training. This can be applied to the layers of a Feedforward Neural Network (FNN) to normalize inputs during training for predicting body fat percentage. Below is an illustration of how batch normalization technique was applied:

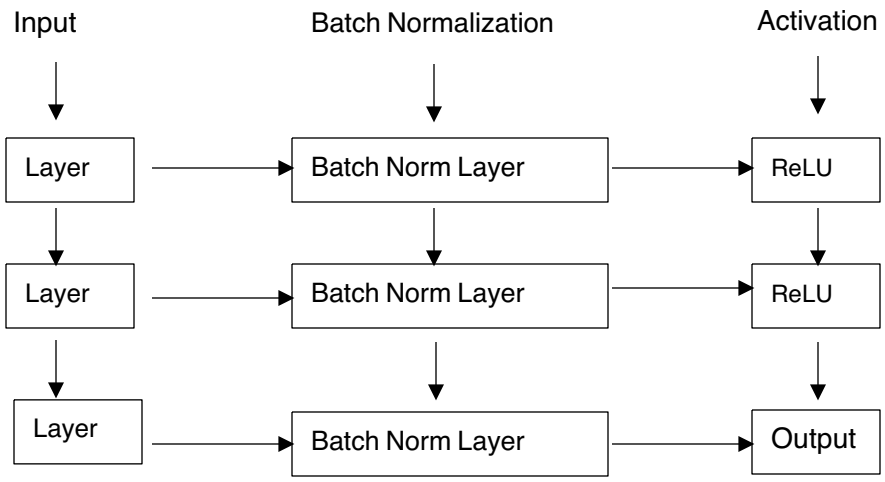

Fig 3.4: Batch Normalization Technique

From the diagram above:

- The batch normalization is integrated into the layers of FNN architecture to improve training stability and efficiency of this research
- Each layer of the neural network (fully connected layer) is followed by a batch normalization layer.
- The batch normalization layer normalizes the activations of the previous layer using batch wise statistics (mean and variance)
- The normalized activations are then scaled and shifted using learnable parameters
- The activation function (ReLU) is applied after batch normalization
- The final output layer produces the predicted body fat percentage

II. Data Augmentation:

To improve the training dataset's diversity and the model's capacity to generalize to other data distributions, use data augmentation approaches. In this research, the BMI transformation data augmentation technique will be applied. This technique involves generating synthetic BMI values by applying transformations to the existing BMI values. It is applicable because it introduces variations in BMI values, which can help improve the model's ability to generalize to different body compositions. It can help improve the model's robustness and generalization performance. By introducing variations in BMI values, this technique helps bridge the gap between the training data and real-world scenarios, resulting in more reliable and robust predictions of body fat percentage from BMI.

Below is an illustration of how this technique can be applied:

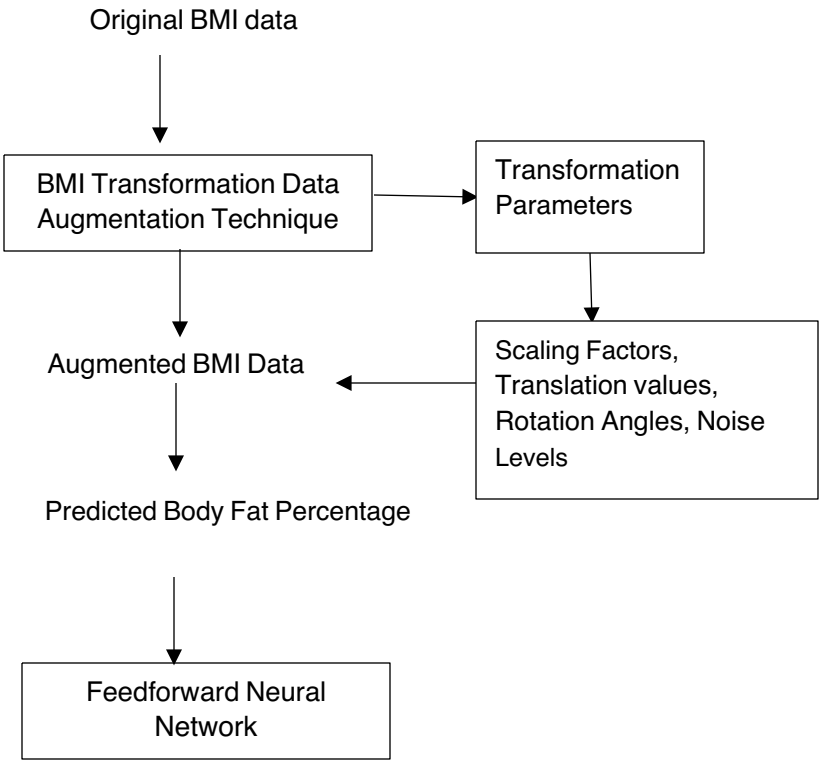

Fig 3.5: BMI transformation Data Augmentation Technique

In the diagram above,

- The original BMI data is augmented using the data augmentation techniques to generate synthetic samples.
- Transformation parameters such as scaling factors, translation values, rotation angles and noise levels are applied to each BMI value
- The augmented BMI data is generated by applying these transformations, resulting in additional synthetic data points
- During the training the FNN learns to predict the body fat percentage based on the augmented BMI data
- To evaluate the model's performance, its predictions are compared to the ground truth body fat percentage values.

3.5 Description of validation technique(s) for proposed solution (Experimental procedures including dataset collection/description, formal proving, mathematical proving, simulation procedures)

A proposed method for employing feedforward neural networks (FNNs) to predict body fat % from BMI usually requires a number of experimental steps, such as dataset description and collection, formal proving, and mathematical proving. Description of validation procedures can be provided below:

3.5.1 Dataset Collection and Description:

I. **Dataset Collection**:

- Dataset containing BMI, age, gender and Body Fat percentage will be downloaded from Kaggle (www.kaggle.com).

  The URL is - https://www.kaggle.com/datasets/karthikeyanrajuz/medical-insurance-prediction-dataset. This dataset consists of AGE, GENDER, Body Mass Index (BMI) and Body Fat Percentage (BF %). The specific dataset that will be used are the BMI and BF%

II. Dataset Description:

- This dataset consists of AGE, GENDER, Body Mass Index (BMI) and Body Fat Percentage (BF %). The specific dataset that will be used are the BMI and BF%

3.5.2 Experimental Procedures:

I. Model Training:

- Split the dataset into validation and training sets
- Utilizing the training data and the proper hyper parameters, train the FNN model.

II. Hyperparameter tuning:

- To maximize model performance, experiment with various hyperparameter setups (learning rate, number of hidden layers, neurons per layer).

III. Evaluation Metrics:

- To assess the success of the model, use quantitative measures like R-squared, Mean Absolute Error (MAE), and Mean Squared Error (MSE).

- If applicable, take into account other measures such as precision, recall, or F1-score.

IV. Model Interpretability:

- Use interpretability approaches for the model, like feature importance analysis, to see how input features affect predictions.
- Determine how resilient the model is to changes in each of the component features.

3.6 Tools and Frameworks used in the implementation

The implementation of a deep learning model - Feedforward Neural Network (FNN) model for predicting body fat percentage from BMI includes the use of numerous tools and frameworks. The following are a few frequently used resources for configuring and learning neural networks:

3.6.1 Jupyter Notebook:

Jupyter notebooks have become a widely used tool in data science programming. Numerous data science tasks, including exploratory data analysis (EDA), data transformation and cleansing, data visualisation, statistical modelling, machine learning, and deep learning, are carried out using Jupyter notebooks (Kallen 2020)

3.6.2 Google Colab:

Deep learning models can be trained on Google Colab, a cloud-based platform that offers free GPU access. It is Google Drive integrated and supports Jupyter Notebooks (Ali et al., 2020). The Python programme for this research will be written using Google Colab.

3.6.3 GitHub:

GitHub is an online platform designed for collaborative programming and version control. It is frequently used to track project changes, interact with others, and exchange code (Fontana et. al., 2017). This tool will be useful in development stage of writing the code for the research work.

3.6.4 Kaggle:

This is the largest data science community in the world, offering strong tools and resources to support your data science objectives (www.kaggle.com). This tool is used for deriving datasets for this research work

3.6.5 TensorFlow:

Apply deep learning frameworks, such as TensorFlow to implement the FNN model, which offers flexibility and makes experimentation simple.

3.6.6 Keras API:

The Keras framework of python programming is used to implement Feed-forward Neural Network (FNN) models for the training task and performance evaluation of Body fat percentage prediction. This is integrated with TensorFlow and enables quick neural network architecture exploration and prototyping.

3.7 Description of Performance evaluation parameters/metrics

The type of issue, the model's objectives, and the need to account for false positives and negatives all play a role in choosing the right performance evaluation measures. To have an in-depth understanding of model performance, it's typical to combine various metrics. The key performance evaluation parameters and metrics are described as follows:

3.7.1 Mean Squared Error (MSE):

- Definition: The average squared difference between the actual and predicted outcomes is measured by the MSE.
- Interpretation: Better accuracy is indicated by a lower MSE, with 0 indicating a perfect fit.
- Formula: $\frac{1}{N}\sum_{i=1}^{N}\left(y_i-\hat{y}_i\right)^2$

3.7.2 Mean Absolute Error (MAE):

- Definition: MAE measures the average absolute difference between the actual and planned outcomes
- Interpretation: Less MAE indicates greater accuracy, just like MSE does.
- Formula: $\frac{1}{N}\sum_{i=1}^{N}|y_i-\hat{y}_i|$

3.7.3 R- Squared (R^2) or Coefficient of Determination:

- Definition: The percentage of the dependent variable's variation that can be predicted from the independent variables is measured by R-squared.
- Interpretation: A value of R^2 near 0 denotes poor model performance, while a number near 1 indicates a strong fit.

- Formula: $R^2 = 1 - \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}$

3.7.4 Precision, Recall, and F1-Score

I. **Precision:** evaluates how well optimistic predictions are made.

$$\text{Precision} = \frac{\text{True Positives}}{\text{True positives + False Positives}}$$

II. **Recall:** evaluates the model's capacity to capture all occurrences of positivity

$$\text{Recall} = \frac{\text{True Positives}}{\text{True positives + False Negatives}}$$

III. **F1- Score**: A measure that finds a balance between recall and precision

$$\text{F1 – Score} = 2 * \frac{\text{Precision * Recall}}{\text{Precision + Recall}}$$

3.7.5 Explained Variance Score:

- Definition: calculates the percentage of the dependent variable's variation that the model can account for.
- Interpretation: Better model performance is indicated by a higher score.

- Formula: $\text{Explained Variance} = 1 - \frac{\text{Var}(y - \hat{y})}{\text{Var}((y)}$

3.7.6 Receiver Operating Characteristic (ROC) Curve and Area Under the Curve (AUC):

- ROC Curve: A graphical comparison between the true positive and false positive rates.
- AUC: Area under the ROC Curve; better model discrimination is indicated by a value that is closer to 1.

3.7.7 Confusion Matrix

- True Positive (TP): Instances that were precisely predicted as positive.
- True Negative (TN): Instances that were precisely predicted as negative
- False Positive (FP): instances that were not predicted as positive.

- False Negative (FN): instances that were not predicted as negative.

Chapter 4: Result and Discussion

4.1 Preamble

At the core of this research lies the analysis and discussion of the performance of the developed Feed-forward Neural Network (FNN) model for classifying body fat percentage (BF%) based on Body Mass Index (BMI), age, and gender. This section aims to shed light on the model's strengths, weaknesses, and potential for real-world application. The model's performance was dissected across various evaluation metrics, including accuracy, precision, recall, F1-score, and weighted average score. This analysis provided insights into the model's effectiveness in accurately classifying individuals into different BF% categories, particularly for imbalanced categories. Furthermore, the researcher, elucidated on the model's ability to generalize to unseen data, determining its real-world applicability for BF% prediction. To gain a deeper understanding of the model's decision-making process, the researcher delved into its interpretability. By analyzing the learned weights, biases, and connections within the FNN, the section shed light on how the model arrives at its predictions and how it perceives the relationship between features. This understanding will be instrumental in further refining the model and potentially guiding future advancements in deep learning for body composition analysis.

4.2 System Evaluation

This framework, outlines key aspects for evaluating the performance and effectiveness of the FNN model for predicting body fat percentage (BF%) from BMI and other relevant features.

Model Performance Metrics:

a) **Accuracy:** Overall percentage of correctly classified BF% categories.
b) **Precision:** Ratio of true positives (correctly predicted BF% cases) to all positive predictions.
c) **Recall:** Ratio of true positives to all actual BF% cases in a specific category.
d) **F1-Score:** Harmonic mean of precision and recall, balancing both metrics.
e) **Weighted Average F1-Score:** Takes into account class imbalance by weighting F1-score for each category based on its proportion in the data.

Generalization:

a) **Testing on unseen data:** Evaluate performance on a separate dataset not used for training to assess the model's ability to adapt to new data.

Class Imbalance Handling:

a) **Confusion Matrix:** Visualizes the distribution of true positives, false positives, true negatives, and false negatives for each BF% category.

b) **Class-specific metrics:** Analyze precision, recall, and F1-score for each BF% category to identify potential issues with imbalanced classes.

Interpretability:

a) **Feature Importance Analysis:** Analyze the impact of each feature on the model's predictions.

5. Comparative Analysis:

a) **Benchmarking:** Compare the FNN model's performance to other machine learning algorithms for BF% prediction.

4.3 Results Presentation

4.3.1 Data Processing

The BMI dataset were explored for type of features, missing values and outliers. After processing the data, it was discovered that the dataset comprised of numerical and categorical features. Numerical features were; age of participants (years), BMI and body fat percentage, respectively. Other useful information observed with the dataset are missing values as well as outliers for BMI.

Table 4.1: Summary statistics for numeric BMI dataset

Summary statistics	Age	BMI	BF%
Count	24999.000000	24999.000000	24999.000000
Mean	44.919237	31.392903	28.812593
Std	16.107162	7.718882	8.632413
Min	16.000000	12.300000	11.000000
25%	31.000000	26.300000	21.000000
50%	45.000000	30.800000	31.000000
75%	59.000000	35.300000	36.000000
Max	74.000000	100.600000	42.000000

BMI = Body Mass Index; BF% = Body Fat Percentage; std = Standard Deviation; min = Minimum; max = Maximum

Table 4.1 is a summary statistics of numerical BMI dataset. As can be seen on Table 4.1, are the total number (24999) of cases investigated, mean age and standard deviation of cases, respectively. Furthermore, Table 4.1 displayed the 5-point summary of for each of the numerical features for BMI dataset. The five-point summary statistics, shows that the feature, BMI has outliers. This observation verifies results in Figure 4.1.

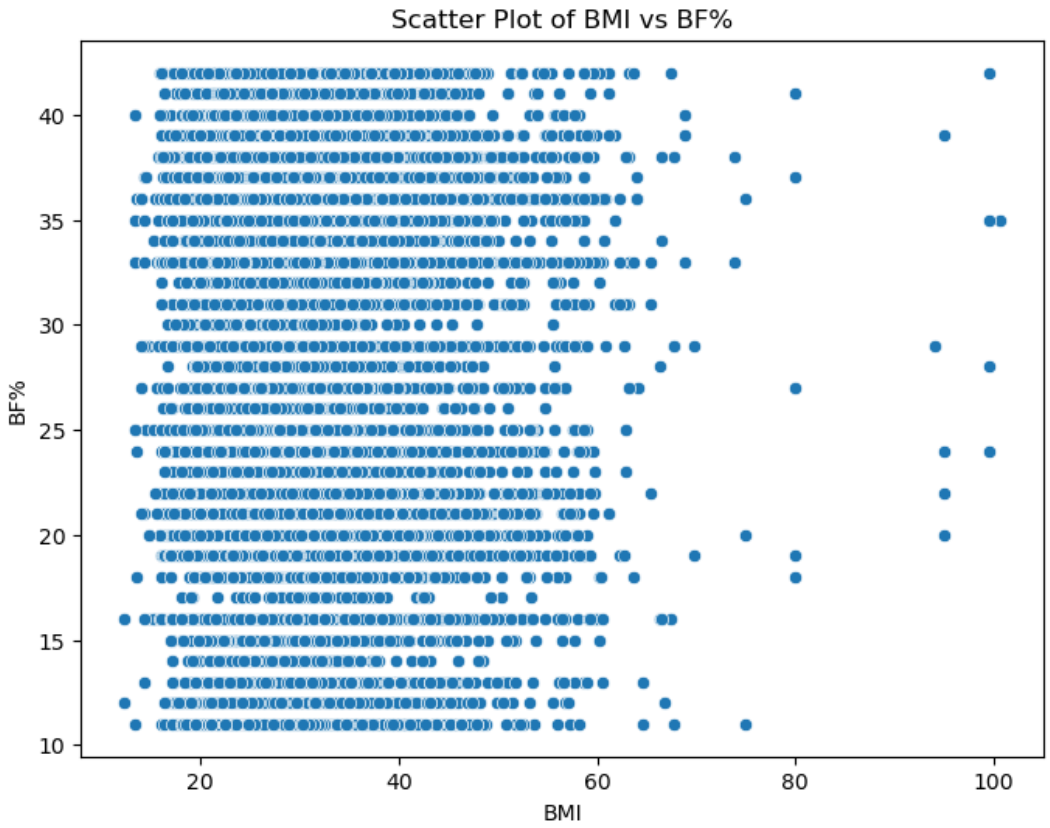

Fig 4.1: A scatter of BMI against BF%

As clearly seen in Figure 4.1, some data points, were distributed farther away from the rest. Revealing abnormality in data behavior. This inconsistency, was captured for cases whose BMI values fell within 60 to 100. BMI values for humans within this range is not realistic according to World Health Organization. The scatter plot shows a positive correlation between Body Mass Index (BMI) and Body Fat Percentage (BF%), indicating that higher BMI values generally correspond to higher BF% values. However, the plot also reveals significant variability, suggesting that the relationship is not linear. BMI is not a sole indicator of body fat composition, and other factors like genetics, physical activity, diet, hormonal factors, and overall health status also influence BF%. The plot does not reveal underlying causes or specific individual circumstances, suggesting a more comprehensive approach to assessing body composition and overall health.

Table 4.2: Summary report for outliers in BMI

Variables	**Number of missing values**
Age	0
Gender	0
BMI	89
BF%	0
Age Group	0
Category of BF%	0

BMI = Body Mass Index; BF% = Body Fat Percentage

Results on Table 4.2, reported 89 cases of outliers for the feature BMI.

Table 4.3: Summary statistics for categorical data for BMI dataset

Variables	**Counts**	**Percentages**
Gender		
Male	16421	65.69
Female	8578	34.31
Age Group (years)		
< 18	336	1.34
18-34	7470	29.88
35 – 44	4604	18.42
45 – 54	4453	17.81
55 – 64	4411	17.64
≥ 65	3725	14.90
BF% Category		
Normal	6764	27.06
Abnormal	18235	72.94

Results on Table 4.3, is a summary statistics for categorical feature for BMI dataset. Data on the table shows that majority (65.69) of the cases investigated were male. After inspecting BMI dataset for feature type and outliers, the dataset, was further inspected for missing values.

Table 4.4: Evidence of missing values in BMI dataset

Variables	**Number of missing values**
Age	0
Gender	0
BMI	990
BF%	0

BMI = Body Mass Index; BF% = Body Fat Percentage.

Data on Table 4.4 shows that BMI dataset had some of its entering for the feature BMI as missing values. So, for having a balanced dataset, missing values observed for the feature BMI was imputed using k-nearest neighbor based on age group. The feature age, was transformed into categories (i.e., < 18, 18 – 34, 35 – 44, 45 – 54, 55 – 64, 65+). Cases were stratify by age group so that values missing for BMI were treated considering the robustness of homogeneity.

Table 4.5: Evidence of no missing data after imputed using k-nearest neighbor based on age group

Variables	**Number of missing values**
Age	0
Gender	0
BMI	0
BF%	0
Age group	0

BMI = Body Mass Index; BF% = Body Fat Percentage.

Summary reports on Table 4.5, revealed that the feature BMI no longer have missing values after imputing for missing values.

Table 4.6: Summary report of numerical features of BMI dataset cleaned from missing values and outliers

Summary statistics	Age	BMI	BF%
Count	24999.000000	24999.000000	24999.000000
Mean	44.919237	31.392903	28.812593
Std	16.107162	7.718882	8.632413
Min	16.000000	12.300000	11.000000
25%	31.000000	26.300000	21.000000
50%	45.000000	30.800000	31.000000
75%	59.000000	35.300000	36.000000
Max	74.000000	59.900000	42.000000

Recalled that the feature BMI, had outliers. This abnormality was treated in a similar fashion like in the case of missing values; the 89 outlier (Table 4.2), were deleted and re-imputed using the k-nearest neighbor technique based on the age group of cases.

Table 4.7: Distribution of body fat percentage by categories

BF% Categories	Counts	Percentage
Normal	6764	27.06
Abnormal	18235	72.94

BMI = Body Mass Index; BF% = Body Fat Percentage

Data on Table 4.7 shows the distribution of body fat percentage of cases based on the categories of body fat percentage. The feature body fat percentage, BF%, was transformed into categories (i.e., normal or abnormal) in accordance to Human Kinetic benchmark for a healthy body fat percentage of an individual, considering both gender and age, respectively (Human Kinetic, 2024). Data on Table 4.7 shows how widely imbalanced cases were distributed across the respective categories.

4.3.2 Feature Engineering

In the initial phase of feature engineering, careful consideration was given to the selection of pertinent features from the BMI dataset to serve as predictor variables (X) in the model.

Specifically, features such as BMI, GENDER, and AGE are chosen based on their anticipated impact on the target variable, body fat percentage, BF%_coded (y) based on reports in literature.

Following the selection of features, categorical variables, such as the GENDER column, undergo a transformation known as one-hot encoding. This process, facilitated by the pd.get_dummies() function, converted the categorical variable, GENDER, into a binary matrix format. A separate binary column represented by each distinct category within the GENDER column. By default, it drops one of the categories to avoid introducing multicollinearity (correlation between the new features). This creates a new set of features representing gender and avoids issues with the model interpreting the order of the categories in GENDER. This transformation aided in effectively handling categorical data by enabling the model to interpret and utilize this information accurately.

Subsequently, the dataset undergoes partitioning into distinct subsets for training, validation, and testing purposes. This partitioning, orchestrated by the train_test_split() function, ensured that the model's performance is rigorously evaluated on unseen data. Notably, the stratification of this split aligned with the target variable ('BF%_coded') to uphold the distribution of classes within each subset.

Finally, the features (predictor variables) are subjected to standardization using the StandardScaler() function. Standardization operates by transforming the data to possess a mean of 0 and a standard deviation of 1. This normalization process serves to enhance the convergence of machine learning algorithms and mitigate the sensitivity of the model to variations in the scale of input features.

4.4 Analysis of the Results

4.4.1 Models Developed

Table 4.8: Architectures of models developed for classification

Models	Hidden Layers	Activation functions	Number of neurons
1.	2	Tanh, sigmoid	3, 64, 31, 1

2.	4	Tanh, sigmoid	3, 64, 32, 16, 8, 1
3.	4	Tanh, sigmoid	3, 64, 31, 16, 8, 1
4.	1	Tanh, sigmoid	3, 8, 1
5.	1	Tanh, sigmoid	3, 31, 1
6.	1	Tanh, sigmoid	3, 32, 1

Six different neural networks were developed with varying hidden layers and neurons. The activation functions centered on the hyperbolic tangent (Tanh) and the sigmoid function because they showed superior performance compared to other activation functions during preliminary analysis. Experimenting with these different architecture, enabled the researcher to select the one that yields the best performance in terms of accuracy, precision, recall, f1-score and weighted average scores.

Table 4.9: Evaluation metrics for models developed for classification

Evaluation metrics (%)		M1	M2	M3	M4	M5	M6
Accuracy		70	61	70	63	63	61
Precision	Wap	74 (63)	76 (64)	75 (64)	76 (64)	76 (65)	77 (65)
Recall	War	90 (70)	70 (61)	88 (69)	74 (63)	74 (60)	67 (61)
F1-score	Waf	82 (62)	72 (62)	81 (65)	75 (64)	75 (62)	72 (62)

M1 to M2 = model 1, model 2, model 3, model 4, model 5, model 6

The results on Table 4.9 show the evaluation metrics for the models developed for classification. The metrics revealed the performances of all six models using accuracy, precision, recall, f1-score and weighted average. Result on Table 4.9 revealed that Model 1 caught many actual cases for bady fat percentage (high recall of 90), but was not able to include some false positives (lower precision of 74). The values for WAP and WAF suggested a balance between precision and recall, but it might not be the most optimal. Further results, showed that Model 2 shares some similarities with Model 1. Model 2 had good precision (76), focusing on identifying true positives, but the lower recall (70) indicates it might miss some relevant cases.

Model 3, stand as a strong candidate. This is because; Model 3 has a well-rounded performance across most metrics. It achieved a decent accuracy (70), good precision (75), and a strong F1-score (81), which indicates a good balance between the two. Additionally, the values for its weighted

averages (WAP, WAR, WAF) were all balanced, suggesting that it performed consistently well considering class imbalance in the BMI dataset.

Models 4 and 5 follow a similar pattern to Model 2. However, they prioritize precision (both at 76), but the lower WAR values (74 and 60) compared to Model 3 suggesting that they struggled in capturing all positive cases, particularly for the minority class. Model 6 stands out a bit. While it boasts high precision (77), its lower accuracy (61) and recall (67) suggested that it prioritizes true positives at the expense of missing relevant positive cases. Additionally, its lower WAP and WAF values, indicated a potential bias towards precision.

Based on the provided metrics, Model 3 achieves the highest accuracy (70%) and a balanced performance across precision, recall, and F1-score. Additionally, Model 3 has the highest weighted average precision, recall, and F1-score among all models, indicating better handling of class imbalance and overall effectiveness. Therefore, Model 3 appears to be the best-performing model for the given task. Hence, Model was selected for hyperparameter tuning.

4.4.2 Hyper parameter tuning for the selected FNN architecture

Table 4.10: Hyper parameter tuning for selected model

Parameters		**Best parameter**
Activation function	Tanh, relu	Tanh
Drop-out rate	0.0, 0.1	0.0
Learning rate	0.001, 0.01	0.001

The combination of tanh and relu activation function, a learning rate of 0.001, and no dropout regularization (dropout rate of 0.0) indicates that the model achieved the best performance with a conservative approach to optimization. It suggests that the model learned effectively from the data without the need for dropout regularization, and the tanh activation function facilitated better representation of non-linear relationships within the data. The selection of a lower learning rate further ensured stable convergence during training, leading to improved model performance.

4.4.3 Model Interpretability

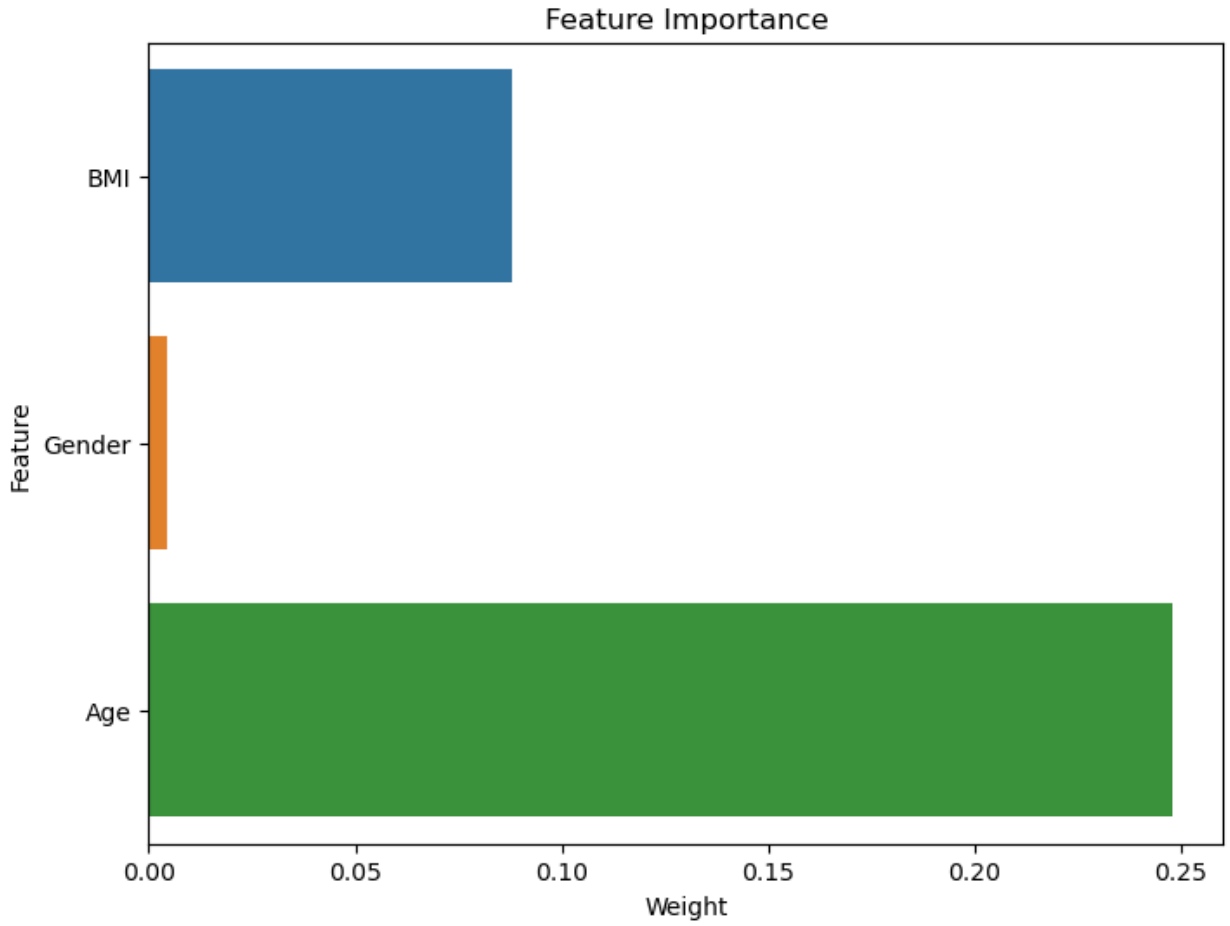

Figure 4.2: Feature importance contribution to body fat percentage based on learned weight

Result from Figure 4.2, showed how the selected FNN architecture makes predictions and elucidate the connection between BMI and body fat percentage as learned by the model. The length of the bars represents the contributions of the features in predicting body fat percentage, while the sign of the weights, showed the nature of relationship between the features and body fat percentage. The feature AGE had the longest bar, suggesting that AGE had the most substantial impact on the model's predictions compared to Gender and BMI. The weight associated with AGE is positive, indicating that means that AGE positively contributed to predicting body fat percentage.

4.4.3 Fine tuning selected Model

Table 4.11: Evaluation metrics for FFNN algorithms

Evaluation metrics (%)		**FFNN**
Accuracy		60
Precision	Wap	78 (66)
Recall	War	63 (60)
F1-score	Waf	70 (62)

Attempts were made by the researcher to exclude the feature GENDER in the model due to the insights gained as regards the contribution of each feature to model prediction. However, attempt made did not improve the model performance. Hence, analysis under this section retained all features. The reported performance metrics on Table provide a comprehensive evaluation of the model's classification capabilities. The model exhibits a precision of 78%, indicating a high level of accuracy in correctly identifying cases belonging to the actual body fat percentage category. However, while precision is high, the recall metric is reported at 63%. This implies that the model captures only a moderate proportion of actual cases of body fat percentage from the entire pool of the actual cases in the BMI dataset. In practical terms, this suggests that while the model is effective in identifying actual cases when it made prediction, it may not be capturing all actual cases, present in the BMI dataset. The F1-score, which combines precision and recall into a single metric, is

reported at 70%. This score indicates a balanced performance between precision and recall. While the model demonstrates a strong precision rate, there is still room for improvement in recall to achieve a more balanced F1-score. The weighted average precision, recall, and F1-score provide an overall assessment of the model's performance, considering the class distribution imbalance. These metrics, at 66%, 60%, and 62% respectively, indicate the model's performance across different classes, weighted by their support in the dataset. Generally, the model showed a promise with a high precision rate, even though there is a need for improvement.

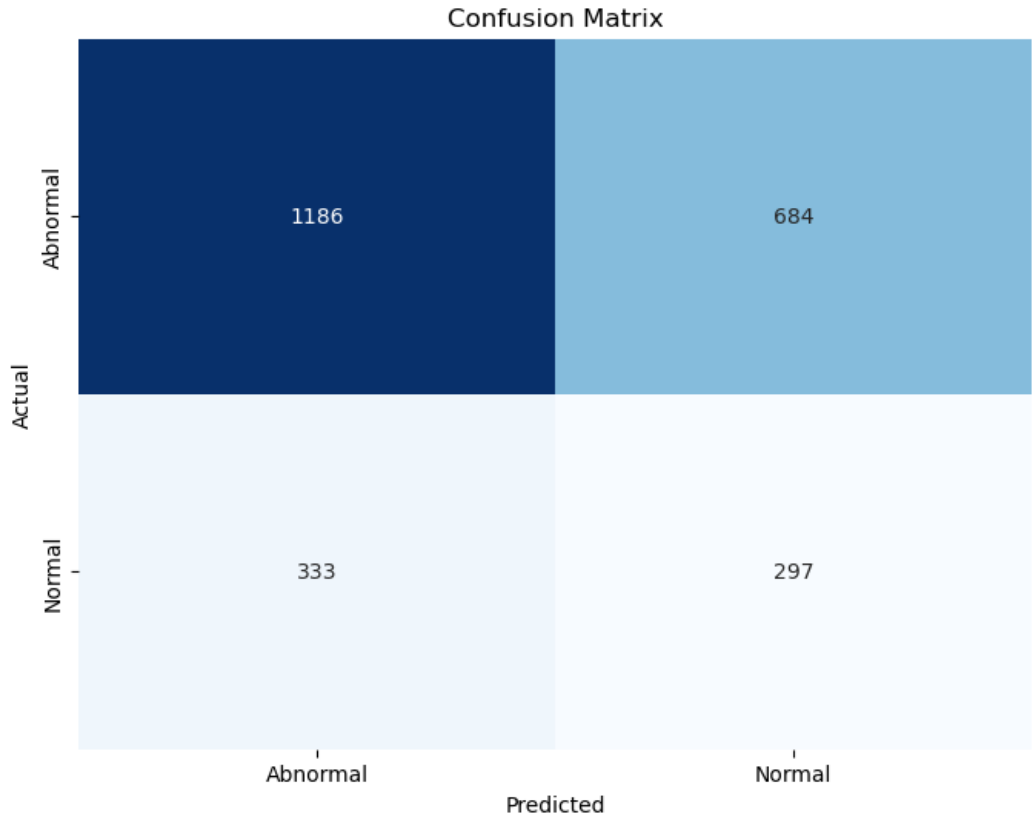

Figure 4.3: Confusion matrix for the FFNN architecture

In Figure 4.3, the rows represent the actual categories of cases that had normal and abnormal body fat percentage, while the columns represent the predicted categories of body fat percentage. The confusion matrix reveals that out of the 639 cases that had normal body fat percentage, feedforward neural network accurately identified 297 of the cases as normal body fat percentage but misclassified 333 as normal body fat percentage. Similarly, out of the 1870 cases that had abnormal body fat percentage, the feedforward neural network correctly accurately identified 1186 cases as having abnormal body fat percentage but misclassified 684 cases as having normal body fat percentage.

4.5 Discussion of the Results

The aim of this research was to develop a classification model for estimating Body Fat Percentage (BF%) from BMI data utilizing a deep learning algorithm, specifically a Feed-forward Neural Network (FNN). This aim was pursued through specific objectives, which involved designing and training an FNN architecture tailored to classifying BF% from BMI and determining the most effective FNN structure for this task.

Six distinct FNN architectures were meticulously developed and evaluated, each characterized by variations in hidden layers and neuron configurations. Activation functions centered on hyperbolic tangent (Tanh) and sigmoid functions, chosen based on superior performance observed during preliminary analyses. Through experimentation with different architectures, the researcher observed the optimal configuration yielding the best performance metrics, including accuracy, precision, recall, F1-score, and weighted averages.

Among the models evaluated, Model 3 emerged as the most promising candidate, demonstrating a well-rounded performance across various evaluation metrics. With a notable accuracy of 70% and strong precision, 75% and F1-score, 81% metrics, Model 3 exhibited a balanced classification performance, effectively navigating the challenges posed by class imbalance within the BMI dataset. This finding aligns with prior research demonstrating the potential of ANNs for this task (Kupusinac et al., 2014). The model's effectiveness in handling class imbalance was further underscored by its balanced weighted average scores, reflecting consistent performance across different class distributions.

The study discovered age as the most influential feature in predicting body fat percentage. This finding resonates with scientific understanding of body composition changes throughout life. Notably, attempts were made to refine the model by excluding the feature, gender, guided by insights into each feature's contribution to model prediction. However, these efforts did not yield improvements in model performance, leading to the retention of all features in the final model architecture. This finding resonates earlier report by Deurenberg et al. (1998) who in their work,

reported that the inclusion of relevant features like age and gender aligns with established knowledge about body fat distribution.

The reported classification metrics of the model after been subjected to an entirely new cases, highlighted its strength in accurately identifying actual cases of body fat percentage, while also indicating opportunities for enhancement, particularly in recall. This indicates that the model might miss a significant portion of actual body fat percentage cases. The literature suggests potential solutions like data augmentation (Nianogo, 2023) and exploring alternative FNN architectures (Megat et al., 2022).

4.6 Implication of the Results

The research aimed to develop a classification model for estimating Body Fat Percentage (BF%) from BMI data using a deep learning algorithm, specifically a Feed-forward Neural Network (FNN). Six distinct FNN architectures were developed and evaluated, with Model 3 emerging as the most promising candidate, demonstrating balanced classification performance and effectively handling class imbalance within the BMI dataset. However, the study also identified opportunities for enhancement, particularly in recall, suggesting potential solutions like data augmentation and exploring alternative FNN architectures. The implications of these findings are significant for both research and practical applications in health assessment and obesity management:

1. **Model Performance and Classification Accuracy:** The study's success in developing a classification model with a notable accuracy of 70%, strong precision, and F1-score of 81% highlights the potential of deep learning algorithms, particularly FNNs, in predicting BF% from BMI data. This indicates promising avenues for further research and the development of more accurate and reliable models for obesity assessment.
2. **Influence of Features on Model Prediction:** The identification of age as the most influential feature in predicting body fat percentage aligns with scientific understanding of body composition changes throughout life. Despite attempts to refine the model by excluding gender as a feature, its retention did not yield improvements in performance, indicating the importance of considering all relevant features in the prediction process. This underscores the complexity of body composition assessment and the need for comprehensive models that capture multiple factors affecting BF%.

3. **Opportunities for Improvement:** While the developed model showed promising performance, particularly in accurately identifying actual cases of body fat percentage, the identified opportunities for enhancement, especially in recall, suggest avenues for further research and model refinement. Strategies such as data augmentation and exploring alternative FNN architectures offer potential solutions to address these limitations and improve the model's overall performance.
4. **Practical Implications for Health Assessment**: The development of accurate and reliable classification models for estimating BF% from BMI data has practical implications for health assessment and obesity management. Such models can assist healthcare professionals in identifying individuals at risk of obesity-related health complications and tailoring interventions to address their specific needs more effectively.

4.7 Benchmark of the Results

Result from the study, showed how the model utilizes age, gender, and BMI for body fat percentage (BF %) prediction. This analysis provided valuable insights into the model's decision-making process as well as addressing the limitations of some existing algorithms deployed by Ferenci et al. (2017). Compared to Ferenci et al. (2017), the broader scope of features (including age and gender) offers a potential advantage in enhancing body fat percentage prediction accuracy.

In terms of features contributions in predicting body fat percentage, the study established that age is one of the most influential factor. The finding that age is the most influential factor aligns well with established scientific knowledge about body composition changes and fat distribution. This therefore, strengthens the model's credibility, as none of the reviewed studies explicitly pinpointed this fact.

The accuracy, 70 % of the FFNN used here, is comparable to other ANN studies demonstrating its effectiveness in predicting BF% for a significant portion of cases (see for e.g., Kupusinac et al. 2014).

As highlighted by in the study, investigating alternative FNN architectures holds promise for potentially improving model performance beyond current results. This aligns with suggestions from Megat et al. (2022).

Below is summary of the related works' performance:

Table 5.1: Comparison of performance measure of related works with current work

RELATED WORK (TITLE)	ALGORITHM USED	PERFORMANCE MEASURES
Ferenci et al. 2017	Linear regression, feedforward neural networks (FNN), and support vector machines.	Support Vector Machines (SVM) performed better than simple regression, but only in terms of stability across bootstrap repetitions; average value (RMSE: 0.0988 ± 0.00288 vs. 0.107 ± 0.012) was not considerably improved.
Kupusinac et. al. 2014	Feed-forward artificial neural network (ANN) with back-propagation	Accuracy: 80.43%
Megat et. al. 2022	Multi-Task Convolutional Neural Network (MTCNN)	Accuracy : 60%

Current research	FNN	Accuracy : 70%

Chapter 5: Summary, Conclusion and Recommendations

5.1 Summary

The aim of the study was to predict body fat percentage from BMI dataset using deep learning Feed-forward Neural Network (FNN). Specifically, the study preprocessed BMI dataset, design and train an architecture of a FNN model to predict body fat percentage from BMI dataset, finally, explored, and determine the most effective FNN architecture for predicting body fat percentage. The proposed solution framework for this research entails several steps: Firstly, in data processing, the BMI dataset was inspected and cleaned of anomalies such as missing values and outliers. The target variable, body fat percentage, was further categorized into two categories: normal and abnormal. Age, gender, and BMI were defined as the input features from the BMI dataset, followed by feature scaling to normalize numerical features for better model convergence. Additionally, the nominal feature, gender, was coded for proper handling by the algorithm. After preprocessing the data, the preprocessed data was further split into training, validation and test sets. Six FNN architectures were designed, involving adjusting layers, neurons, and activation functions to explore complex relationships between body fat percentage and the BMI dataset. These architectures were then trained on the training sets. The performance of each trained model was evaluated on the validation set using evaluation metrics such as accuracy, precision, recall, F1-score, weighted average score for precision, recall, and F1-score. Optimal FNN architectures were explored through model comparison, to determine the architecture with the highest performance metrics. Hyperparameters of the selected architecture was tuned for further optimization, and model interpretability was analyzed to understand predictions based on learned weights and biases. Finally, attempt made on iterative improvement of did not improve model performance. The validation process was then conducted with unseen data (test set). Results showed that a FNN of four hidden layers with neuron counts of (64, 31, 16, 8) for each hidden layer was identified as the optimal configuration that achieved superior performance across a range of evaluation metrics, including accuracy, precision, recall, F1-score, and weighted averages. The identified FNN achieved a commendable accuracy of 70% alongside strong precision (75%) and F1-score (81%). The study revealed age as the most influential feature for predicting body fat percentage. While the implemented evaluation metrics highlighted that the selected model's ability in accurately

identifying a significant portion of actual body fat percentage cases, the study also revealed opportunities for improvement, particularly in recall.

5.2 Conclusion

In conclusion, this study successfully demonstrated the potential of deep learning FNNs as a viable tool for predicting body fat percentage from readily available BMI data. The developed model exhibits good accuracy (70%) and strong precision (75%) and F1-score (81%), indicating its proficiency in correctly classifying body fat percentage for a significant portion of the data. This accomplishment opens doors for further advancements in non-invasive body fat assessment techniques. There are two key takeaways that warrant further exploration. First, in line with accepted scientific wisdom, the study found that the most significant predictor of body fat percentage was age. This emphasizes how crucial it is to take into account variables other than BMI when developing models to predict body fat. Future studies may look into adding characteristics like muscle mass and degree of physical activity to the model in an effort to increase its generalizability and accuracy.

Second, the study highlighted an opportunity for improvement in recall, suggesting the model might miss some true body fat percentage cases. This opens doors for further refinement. The proposed solutions, like data augmentation techniques and exploring alternative FNN architectures, hold promise for enhancing the model's ability to capture a wider range of body fat percentage cases. Additionally, incorporating more diverse datasets in the training process could improve the model's ability to handle variations in body composition across different populations.

With further refinement, such models have the potential to become valuable tools in the healthcare field, particularly for applications in health assessment and obesity management. The ability to accurately predict body fat percentage using non-invasive methods like BMI could significantly impact preventative healthcare strategies. Imagine a scenario where a quick BMI measurement and a simple FNN model could flag individuals at risk of obesity-related health complications, allowing for early intervention and personalized treatment plans. This could lead to improved patient outcomes and potentially reduce the burden of obesity-related diseases on healthcare systems.

5.3 Recommendations

1. The study identified age as a significant factor, incorporating additional features like muscle mass, physical activity levels etc. could significantly improve model accuracy. This expanded feature set would provide a more holistic representation of body composition, leading to more precise predictions.

2. Explore advanced deep learning architectures like Convolutional Neural Networks (CNNs). The current FNN achieved good results, exploring more advanced architectures like CNNs could potentially improve performance.

3. Model generalizability could be enhanced through data augmentation techniques. The identified issue with recall (missing true positives) can be addressed through data augmentation. This involves strategically manipulating existing data (adding noise, random transformations) to create variations and effectively increase dataset size and diversity. This enriched training data can improve the model's ability to handle unseen scenarios and potentially boost recall.

4. The current dataset might not encompass the full spectrum of body types. Collaboration with healthcare institutions or utilizing publicly available datasets from biobanks or health surveys across various regions could provide data from more diverse populations. This broader and more balanced representation can improve the model's generalizability and reduce potential biases.

5.4 Contribution to Knowledge

This study contributes to knowledge in several significant ways:

1. The research demonstrates the efficacy of Feed-forward Neural Networks (FNNs), a deep learning technique, in predicting body fat percentage from readily available BMI data. This exploration of a relatively new approach in this domain establishes its potential as a non-invasive method for body fat estimation.

2. The findings reinforce established scientific knowledge by highlighting age as a crucial factor influencing body fat percentage. This lends credence to the model's results and underscores the importance of incorporating age into body fat prediction models for improved accuracy.

5.5 Future Research Directions

The study presented some interesting avenues for future research on body fat prediction using deep learning:

1. The study highlights areas where the model can be improved, particularly in recall (identifying true body fat cases). This paves the way for further research on data augmentation techniques, exploring different neural network architectures, and incorporating more diverse datasets.
2. Future research should investigate the potential of employing complementary deep learning techniques, such as Convolutional Neural Networks (CNNs). This might be particularly valuable if image data, such as body scans, becomes available for body fat percentage prediction.

AFRICA CENTRE OF EXCELLENCE ON TECHNOLOGY ENHANCED LEARNING (ACETEL)

Topic:

A COMPARATIVE ANALYSIS OF THE EFFECTIVENESS OF THE PERFORMANCES OF K-MEANS AND FUZZY C-MEANS CLUSTERING ALGORITHMS ON SEGMENTATION OF STUDENT LEARNERSHIP USING ACADEMIC PERFORMANCE

A PROJECT

Prepared for the MSc. Program at the Department of Artificial Intelligence, National Open University of Nigeria, Abuja.

JOSEPH ANANE-ADJEI

April 2024

DECLARATION

I hereby declare that this submission is a project work done by me and submitted to the National Open University of Nigeria, Abuja, in partial fulfilment of the requirements for the award of master of science in artificial intelligence, 1 and a half year.

DEDICATION

This thesis is dedicated to God Almighty, whose unwavering mercy, grace, and divine support have been the cornerstone of my academic journey.

To my family, for their boundless love and belief in my abilities. Your sacrifices and prayers have been my guiding light.

To my supervisor (Dr. Olaide Oyelade) and mentors, for their invaluable guidance and patience throughout this research.

And to all the students and educators, whose dedication to knowledge and learning continues to inspire meaningful innovations in the field of education.

Thank you all for being a part of this journey.

ABSTRACT

This thesis conducts a comparative analysis of K-means and Fuzzy C-means (FCM) clustering algorithms in segmenting students' learnership based on academic performance. It applies advanced preprocessing techniques such as normalization, outlier removal, and Principal Component Analysis to prepare the dataset. K-means, with its fast convergence and clear segmentation, proved efficient for large-scale applications, but it's hard clustering approach often oversimplified data, neglecting overlapping student characteristics. FCM, on the other hand, provided nuanced insights into overlapping profiles, albeit with higher computational costs and sensitivity to parameter tuning. Both algorithms exhibited biases: K-means favored equal-sized clusters, misrepresenting smaller groups, while FCM's sensitivity to initialization influenced cluster memberships. The study underscores the importance of choosing algorithms based on dataset attributes and objectives, recommending K-means for speed and simplicity, and FCM for detailed analyses. It advocates for robust preprocessing, parameter optimization, and hybrid approaches to enhance clustering outcomes. Future research could explore scalability, advanced tuning techniques, and alternative clustering methods like Hierarchical Clustering or DBSCAN for improved educational data mining and personalized learning strategies.

Keywords: K-means, Fuzzy C-means, clustering, Learnership, student Learnership segmentation

CHAPTER 1

1. INTRODUCTION

1.1 Background to the study

According to A. Niyungeko (2020), education in Africa is a legacy of the colonial system, which was not designed to foster entrepreneurship in conquered nations. Modules with little to do with entrepreneurship but the majority of courses were content-based. Also, university-offered courses lack a connection to the demands of the labor market and are more theoretical than practical. There is a limitation on the part of professional courses and graduates are well-versed in theoretical knowledge (Murphy, 2012). The African education sector continues to face significant obstacles, including limited and unequal access to school, irrelevant curricula and poor learning outcomes, a lack of political commitment and funding, an underdeveloped education system, and a weak connection to the labor market (Albert et al., 2010). The above works of A. Niyungeko (2020) and Albert et al. (2010) clearly connotes obstacles to economic growth and social equity.

Both an instrument of transformation and of stability, education (Naibi, 1972). (Murphy, 2012) defined education as the process of teaching, training and learning especially in schools or colleges to improve knowledge and develop skills. Since education is the most important tool for change and any significant shift in the intellectual and social outlook of any society must be preceded by an educational revolution, it was stated in the South African National Policy on Education that "education shall continue to be highly rated in the national development plans." Also, Nigeria, which is the largest African country in time of population and ranked sixth [1] most populous country in the world keeps

developing educational policies and program to ensure the realization of education for all (Ogunode & Adah, 2020).

This is to spark a shift in paradigm with respect to the early and present state of education.

According to Babb & Meyer (2005), prioritizing critical skills for growth and development, promoting employability and sustainable livelihoods through skills development and improving the quality and relevance of skills are among the key areas for human resource development. In line with the afore mentioned key areas and others, learnerships were developed (Karlsson & Berger 2006). Student learnership which is a useful tool for preparing learners help to bridge the gap between content-based education and skill-oriented education; that is, student learnership fills the skills development gap.

A learnership is a structured learning process for gaining theoretical knowledge and practical skills in the workplace leading to a qualification with respect to a National Qualification Framework (NQF). Learners participating in learnerships have to attend classes at a college or training center to complete classroom-based learning, and have to complete on-the-job training in a workplace which must be relevant to the qualification (South African Qualification Authority, 2014) [2]. Learnership training can also take the form of virtual facilitations where trainers (Facilitators) facilitate learning process online using Learning Management Systems and other education software. Learning management system provide educators with a platform to distribute information, to engage students and manage distance or online classes more effectively.

Segmentation of student learnership which is the aggregation of students into groups or segments with common characteristics and who respond similarly to learnership actions. It

helps educational institutions to identify or reveal distinct groups of students who think and function differently and follow varied approaches in their learnership program. The dataset of students can be segmented depending on factors including gender, educational background, and previous board results [3]. By putting students in comparable classes, educational institutions can benefit from the use of clustering in EDM. This aids in extracting the relevant characteristics from the student dataset, and the outcomes can be utilized to track and forecast students' academic development thereby ascertaining the effectiveness of student learnership.

Therefore, it is important to conduct a comparative analysis on the effectiveness of some clustering algorithms, specifically the k-means and fuzzy c-means algorithms on segmenting student learnership using a suitable data mining tool. This will help to further broaden the understanding of educational institutions on better ways to sustain growth and make informed deductions knowing how effective student learnership fills the skills development gap through the use of very effective models.

1.2 Statement of Problem

Student learnership aims to integrate theoretical education and skills training in both the learning program and in the assessment process. However, an indebt understanding hasn't been critically considered by some organizational institutions and individual trainers concerning the effectiveness of learnership program.[2] As a matter of fact, many students drop out despite the huge investments (resources, time and energy) in the program and some haven't put in the needed capacity to excel.

Sumari, Nadia & Natasja (2023) from an organizational standpoint of view makes it clear that although the primary objective of learnerships is to develop vocational skills, the organization and even larger community also reap benefits from hosting learnerships. They went further to say that these benefits include lower recruitment costs, capacity building with employees that understands the culture of the organization, simplified onboarding and community involvement. Furthermore, Rankin, Roberts & Schöer (2018) conducted an analysis of student academic performance using clustering techniques. Students' performance is an essential part in higher learning institutions. Predicting students' performance becomes more challenging due to the large volume of data in educational databases. Clustering is one of the methods in data mining used to analyze the massive volume of data. It categorizes data into clusters such that objects are grouped in the same cluster when they are similar according to specific metrics. Kyle & Margaret (2015) also conducted a comparative performance analysis of clustering techniques in educational data mining. They compared partition-based, density-based and hierarchical methods to determine which technique is the most appropriate for performing clustering analysis with LMS. In conclusion, the partition-based methods produced the highest Silhouette Coefficient values and the better distribution among the clusters.

Johnson, S.E., (1967) investigated the clustering performance of k-means and fuzzy c-means on student learnership data, comparing their accuracy and computational efficiency. His findings provided a comprehensive evaluation of both algorithms, considering multiple dataset characteristics and parameter settings. Yet, it was limited by exploration of the interpretability of clustering results and potential biases in algorithmic outcomes of clustering solutions over multiple iterations and the sensitivity of results to algorithmic

parameters. Syaiful et al. (2018) conducted a comparative study of K-means and fuzzy c-means clustering algorithms for educational data mining. The research presented a comparative study of k-means and fuzzy c-means clustering algorithms in segmenting student learnership data. It evaluated the effectiveness of both algorithms in identifying patterns and clusters in educational datasets. Clustering performance based on metrics such as clustering accuracy, cohesion and separation, cluster effectiveness assessment and meaningfulness in terms of clusters' ability to handle diverse data and uncover patterns, as well as some potential applications such as helping educators tailor teaching methods were findings from their study. Limitations such as data specificity i.e., data not representative of the broader student population, choice of parameter selection for both algorithms, among other factors affected the generalizability of the results.

Akinyemi et al. (2020) conducted a comparative analysis of k-means and fuzzy c-means clustering algorithms in predicting student performance. Their research compared the effectiveness of k-means and fuzzy c-means algorithms in predicting student performance based on various attributes. It examined the strengths and weaknesses of each algorithm in educational data analysis. Some of the findings from their study were; how effectively the two clusters predict student performance based on various attributes (e.g., grades, attendance engagement etc.), ability to identify meaningful clusters that correlate with student performance, the interpretability of clusters formed by each algorithm and their relevance to predicting student performance among other factors.

On the other hand, the following were limitations from the study; data quality and representativeness of dataset used, incompleteness or biased data, algorithms' sensitivity to choose of parameters among other factors.

Each of these research findings contributes valuable insights into the comparative analysis of k-means and fuzzy c-means clustering algorithms in the context of student learnership segmentation. However, algorithmic biases and interpretability of clusters can have higher degree of advertent impact on the segmentation process. Systematic and unfair discrimination that can occur in the decisions made by algorithms arise from various sources including the data used to train the algorithms, design of algorithms and the context in which they are deployed.

Additionally, the degree to which the results of a clustering algorithm can be understood and explained or how easy it is to make sense of the grouping of data points into clusters and to interpret the meaning or characteristics of each cluster is key in enabling stakeholders such as domain experts, researchers or decision-makers to extract actionable insights from clustering results and make informed decisions.

In view of the above, this research will address the interpretability of clusters and the impact of algorithmic biases on segmentation accuracy.

1.3 Research questions

This research study attempts to address the following research questions

1. What is student learnership segmentation?
2. Which is more efficient for student learnership segmentation; k-means clustering algorithm or fuzzy c-means clustering algorithm?
3. Is there room for improvement upon the less efficient clustering algorithm?

1.4 Aim and objectives of the study

The aim of this research study is to conduct a comparative analysis on the effectiveness of the performances of k-means and fuzzy c-means clustering algorithms on segmentation of student learnership using academic performance.

Specific Objectives of the study are:

1. To apply state-of-the-art data processing technique to clean and prepare inputs.
2. To design both k-means and fuzzy c-means algorithms for student segmentation with focus on the interpretability of clusters and the impact of algorithmic biases on segmentation accuracy.
3. To compare to know which clustering algorithm is more efficient for student segmentation than the other in between k-means and fuzzy c-means clustering algorithms.

1.5 Methodology

Objective	***Practical Approach***	***Technical Approach***
Apply state-of-the-art data processing techniques to clean and prepare inputs.	1. Identify the raw data sources relevant to student segmentation, such as demographic information, academic performance records, and extracurricular activities. 2. Preprocess the data to handle missing values, outliers, and inconsistencies using techniques like imputation, outlier detection, and data normalization. 3. Explore and implement advanced data preprocessing methods, such as	1. Provide a detailed description of each data preprocessing step, including the rationale behind the choice of techniques and parameters. 2. Document the tools or software libraries used for data preprocessing, along with any custom scripts or algorithms developed. 3. Discuss any challenges encountered during data preprocessing and how they were addressed to ensure the quality and reliability of the input data

	dimensionality reduction, or noise reduction, based on the specific requirements of the clustering algorithms.	
Design both k-means and fuzzy c-means algorithms for student segmentation with a focus on the interpretability of clusters and the impact of algorithmic biases on segmentation accuracy.	1. Implement the k-means and fuzzy c-means clustering algorithms using appropriate programming languages or software packages. 2. Design experiments to evaluate the interpretability of the clusters generated by each algorithm, considering factors such as cluster compactness, separation, and coherence. 3. Assess the impact of algorithmic biases on segmentation accuracy by varying input parameters, initial cluster centers, or cluster validity indices.	1. Describe the mathematical formulations of the k-means and fuzzy c-means algorithms, including the optimization objectives and update rules. 2. Specify the parameter settings and initialization methods used for each algorithm, ensuring reproducibility and comparability of results. 3. Present metrics or measures for evaluating cluster interpretability and algorithmic biases, such as silhouette scores, cluster validity indices, or qualitative assessments by domain experts.
Compare to know which clustering algorithm is more efficient for student segmentation than the other between k-means and fuzzy c-means clustering algorithms	1. Design a comparative study to systematically evaluate the efficiency of the k-means and fuzzy c-means algorithms for student segmentation. 2. Define performance metrics related to efficiency, such as computational complexity, convergence speed, or memory usage. 3. Implement experiments using representative datasets and varying sizes or characteristics to assess algorithmic performance under different scenarios	1. Present a detailed experimental setup, including the datasets used, parameter configurations, and performance metrics. 2. Conduct statistical analysis to compare the efficiency of the clustering algorithms, using appropriate tests such as t-tests or ANOVA for significance testing. 3. Discuss the implications of the results in terms of algorithm selection for student segmentation tasks, considering trade-offs between efficiency and interpretability.

Table_1.1: Structure of the Methodology

In the above tables, a clear and structured explanation of the methodology, including both practical implementation details and technical considerations relevant to achieving the research objectives have been provided.

1.6 Scope of the Study

Under the scope of this study, an outline is made on the boundaries and extent of the research, specifying the focus areas, objectives, data sources, methodologies, and limitations. The outlined focus areas are explained in detail as follows:

1.6.1 Objective:

The primary objective of this study is to conduct a comparative analysis of the effectiveness of k-means and fuzzy c-means clustering algorithms in segmenting student learnership based on academic performance. The research seeks to assess and differentiate the performance of these clustering methods to uncover their respective advantages and drawbacks in classifying student learning groups.

1.6.2 Data Sources:

Academic performance data from a single educational institution or a chosen sample of educational institutions will be used in the study. Variables including exam results, attendance records, student grades, and other pertinent measures of academic success may be included in the data. The collection of data will adhere to ethical guidelines and be anonymized to protect student privacy and confidentiality.

1.6.3 Methodology:

1.6.3.1 Data Preprocessing:

The study will involve data preprocessing steps such as data cleaning, normalization, and transformation to ensure the quality and consistency of the data used in the analysis.

1.6.3.2 Clustering Algorithms:

The k-means and fuzzy c-means clustering algorithms will be applied to segment the student learnership data based on academic performance. The study will evaluate the performance of both algorithms using various metrics such as silhouette score and other measures of cluster quality.

1.6.3.3 Comparative Analysis:

The performance of k-means and fuzzy c-means clustering will be compared in terms of their ability to segment the data into meaningful groups or clusters. The study will also assess the interpretability of the clustering results and their potential implications for educational policy and interventions.

1.6.3.4 Focus Areas:

Examination of the strengths and limitations of k-means and fuzzy c-means clustering algorithms in the context of student learnership segmentation; Analysis of the impact of different parameter settings on the performance of both algorithms; and Consideration of various evaluation metrics to compare the clustering performance and quality.

1.6.3.5 Limitations:

The scope of the study may be limited by the availability and quality of academic performance data. The findings may not be universally applicable across different

educational institutions due to variations in curriculum, grading systems, and student demographics. Computational resource constraints may affect the scale and complexity of the analysis.

1.6.3.6 Expected Outcomes:

The study aims to provide insights into the comparative effectiveness of k-means and fuzzy c-means clustering algorithms for segmenting student learnership. The need for recommendations for the most suitable algorithm and parameter settings for similar studies in the future; and Suggestions for educational interventions based on the identified clusters and patterns.

1.7 Significance of the study

With the increasing availability of educational data and the development of advanced Machine Learning algorithms, AI has the potential to revolutionize the educational industry by accelerating the transformation of education systems towards student learnership. This research can contribute to the understanding of how clustering, an unsupervised Machine Learning algorithm subjected to AI can be applied in educational data mining. Specifically, this is with respect to understanding the correlation between the higher performing clustering algorithm and the student academic performance. Since, a learnership provides the student with a qualification that is directly related to the work s/he is doing, s/he gains a better understanding of the practicality behind what s/he is doing (the why of their occupation), which will improve their personal performance, and give them the opportunity to study further, or be promoted.

In conclusion, this study in adding to existing research body of knowledge will go a long way to help organizational institutions, policy makers, development practitioners in further understanding how effective student learnership is. Additionally, this study will be a basis for capitalizing on a higher performance clustering algorithm for the segmentation of student learnership and will be a base for the conduction of further study in this field.

1.8 Definition of terms

1.8.1 Learnership

A Learnership is a vocational education and training program to facilitate the linkage between structured learning and work experience in order to obtain a registered qualification. It combines theory and workplace practice into a qualification that is registered on the National Qualifications Framework (NQF). A learnership is a structured learning process for gaining theoretical knowledge and practical skills in the workplace leading to a qualification with respect to a National Qualification Framework (NQF). Learners participating in learnerships have to attend classes at a college or training center to complete classroom-based learning, and have to complete on-the-job training in a workplace which must be relevant to the qualification (South African Qualification Authority, 2014).

Learnership provides work-based learning for a student who is in the process of gaining a qualification. Students engaged in a learnership enter into a contract specific to the learnership for a period between themselves as learners, an employer and a training provider, such as a university or college. The contract clearly indicates terms of reference as well as termination conditions (Department of Social Development 2008).

1.8.2 Clustering

Clustering techniques reveal internally homogeneous and externally heterogeneous groups. Students vary in terms of behavior, needs, wants and characteristics and the main goal of clustering techniques is to identify different student types and segment the student base into clusters of similar profiles so that the process of target learnership can be executed more efficiently. Both, hierarchical and non-hierarchical clustering algorithms are widely used in the segmentation of student learnership. Clustering approaches are constructive tools to investigate data structures and have emerged as choice techniques for unsupervised pattern recognition and are applied in many application areas such as pattern recognition [5], data mining [6], machine learning [7], etc. Generally, clustering can be either hard or soft type. In the first category, the patterns are distinguished in a well-defined cluster boundary region. But due to the overlapping nature of the cluster boundaries, some class of patterns may be specified in a single cluster group or dissimilar group. This property limits the use of hard clustering in real life applications. To reduce such limitations, soft or fuzzy type clustering came into the picture and helps to provide more information about the memberships of the patterns. The Fuzzy clustering problems have been expansively studied and its affiliate problems can be grouped based on fuzzy relation [8][9], fuzzy rule learning [10][11] and optimization of an objective function. The fuzzy clustering based on the objective function is quite popularly known to be fuzzy c-means clustering (FCM) [12][13].

1.8.3 K-means clustering

K-means is one of the simplest clustering algorithms.[14] It uses an easy process to group a given data into a specified number (k) of clusters. The main idea is to define k central

points (centroids), one for each cluster. The choice of initial centroids is important as different choices might lead to different resulting clusters. A good rule of thumb is the choice of initial centroids is to place the centroids far away from each other as possible. In a dataset, a desired number of clusters k and a set of k initial starting points, the k-means clustering algorithm finds the desired number of distinct clusters and their centroids. A centroid is the point whose co-ordinates are obtained by means of computing the average of each of the co-ordinates of the points of samples assigned to the clusters.

The steps for implementing the k-means algorithm are [15]*;*

1. Set k - To choose a number of desired clusters, k.
2. Initialization - To choose k starting points which are used as initial estimates of the cluster centroids. They are taken as the initial starting values.
3. Classification - To examine each point in the dataset and assign it to the cluster whose centroid is nearest to it.
4. Centroid calculation - When each point in the data set is assigned to a cluster, it is needed to recalculate the new k centroids.
5. Convergence criteria - The steps of (3) and (4) require to be repeated until no point changes its cluster assignment or until the centroids no longer move.

1.8.4. Fuzzy c-means clustering

Fuzzy c-means (FCM) is a data clustering technique in which a data set is grouped into n clusters with every data point in the dataset related to every cluster and it will have a high degree of belonging (connection) to that cluster and another data point that lies far away from the center of a cluster which will have a low degree of belonging to that cluster. FCM is an unsupervised clustering algorithm that is applied to wide range of problems connected

with feature analysis, clustering and classifier design. FCM is widely applied in agricultural engineering, astronomy, chemistry, geology, image analysis, medical diagnosis, shape analysis and target recognition.[16] With the development of the fuzzy theory, the FCM clustering algorithm which is actually based on Ruspini Fuzzy clustering theory was proposed in 1980's. This algorithm is used for analysis based on distance between various input data points. The clusters are formed according to the distance between data points and the cluster centers are formed for each cluster.

1.8.5. Student Learnership Segmentation

Student Learnership Segmentation is a method of creating separate sets of perspective students who are characterized by common needs in order to generate varied learnership strategies for targeting each group according to its characteristics. Academic Institutions can improve their decisions and policies based on the student academic performance upon studying and analyzing large volumes of collected student academic data. According to [17], customer segmentation which enables the allotment of customers into groups helps business entities to generate maximum profits when their resources have been utilized judiciously geared towards cultivating the most loyal and useful group of customers. Based on their buying behavior, frequency, demographics etc., the total customer set can be divided and grouped into clusters. This makes it easier for firms to group similar customers together in better addressing their needs rather than having to tackle each customer need separately.[18] Likewise, the early classification of university students according to their potential academic performance can be a useful strategy to mitigate failure, to promote the achievement of better results and to better manage resources in higher education institution.[19]

In addition to the afore mentioned, the segmentation process also helps institutions to make informed decisions on analyzing changing student academic performance. Segmentation of student academic performance using clustering algorithms is virtually a potential tool which serves the purpose of a guide for developing new ways of realizing student learnerships.

1.9. Organization of the thesis

The study is divided into five (5) chapters. Chapter one of the study consists of the general introduction which includes; the background of the study, the statement of the problem, the objective of study, the research questions, significance of the study, the scope of study, the definition of terms and the organization of the study. Chapter two is the literature review which evaluates the works of other researchers on the subject, their approaches, and the researcher's criticisms of the study. Chapter 3 gives a detailed description of how the study is actually carried out; the exact data you collected; how, when, how often and where it was collected; how the data were managed (entered into a database); what the database is and the analytical tests undertaken. Finally, chapter 4 and 5 presents the results (as narrative, tables, graphs and figures) and discussions (an interpretation of the results, what they mean and results comparation with previous studies or pre-existing knowledge of the subjects) of the research.

CHAPTER 2

2. LITERATURE REVIEW

2.1 Introduction

In data mining and machine learning, clustering is a basic technique that groups a set of items so that the objects in the same group (or cluster) are more similar to each other than to the objects in other groups. Pattern recognition, image analysis, information retrieval, bioinformatics, and market research are just a few of the fields in which this technique finds extensive application. Numerous types of clustering algorithms fall under this general category, such as partition-based, hierarchical, density-based, and model-based techniques. Every category has its applications and methods.

2.2 Clustering Algorithms

2.2.1 Partition-based Clustering:

- **K-means**: K-means, one of the most used clustering algorithms, divides the data into K clusters, with the mean of each cluster serving as a representative. Every data point is iteratively assigned to the closest cluster center by the algorithm, which then updates the centers according to the cluster members in use. Although it is sensitive to the original cluster centers and outliers and necessitates specifying the number of clusters beforehand, its popularity stems from its simplicity and efficiency (Jain, 2010; Wu et al., 2008).

- **Fuzzy C-means**: Similar to K-means, FCM is a partition-based clustering technique, but it varies in that it permits data points to be part of several clusters with different

levels of membership. Because of its adaptability, FCM offers a more sophisticated method of clustering and is especially helpful in situations where the data may not readily divide into discrete clusters (Dunn, J. C., 1973).

- **K-medoids**: Similar to K-means, but the medoid (the most centrally located object) represents each cluster instead of the mean. This makes K-medoids more robust to noise and outliers (Kaufman & Rousseeuw, 1990).

2.2.2. Hierarchical Clustering:

Using a top-down (divisive) or bottom-up (agglomerative) strategy, this method creates a hierarchy of clusters. It creates a dendrogram, a figure that resembles a tree and captures the sequences of merges and splits, without requiring the number of clusters to be predetermined (Murtagh & Contreras, 2012). Each data point is initially clustered separately in agglomerative clustering, which iteratively merges the closest pairings of clusters until all points are in a single cluster or a stopping requirement is satisfied (Sneath & Sokal, 1973). In contrast, divisional clustering begins with every point in a single cluster and divides them recursively (Jain & Dubes, 1988).

2.2.3. Density-based Clustering:

- **Applications with Noise Using Density-Based Spatial Clustering**: DBSCAN Points in low-density areas are identified as outliers by this technique, which clusters points that are densely packed together. It requires two parameters: the neighborhood radius and the minimum number of points needed to create a cluster, yet it is efficient at handling noise and discovering clusters of any shape (Ester et al., 1996).

- **Ordering Points to Determine the Clustering Structure or OPTICS:** Ankerst et al. (1999) created an updated ordering of the database that represents the density-based clustering structure of DBSCAN, addressing its susceptibility to parameter changes.

2.2.4. Model-based Clustering:

These algorithms operate on the assumption that a variety of underlying probability distributions, each of which represents a distinct cluster, produce the data. The most popular method is called the Gaussian Mixture Model (GMM), in which each cluster is represented as a Gaussian distribution and the parameters are estimated using the Expectation-Maximization (EM) algorithm (Fraley & Raftery, 2002).

2.3. Applications of Clustering Algorithms

2.3.1. Applications in Data Analysis

Clustering algorithms are applied across various fields to uncover patterns and structures in data that are not immediately apparent.

In the commercial world, clustering is used to divide clients into groups according to their purchase patterns, demographics, and other characteristics. This supports customized services and targeted marketing (Sarstedt & Mooi, 2019). Clustering is used to group similar images or patterns, aiding in image retrieval, compression, and identification applications. For instance, clustering can aid in diagnosis in medical imaging by identifying comparable regions within an image (Duda et al., 2001). One important use case for clustering is document clustering, which is the application of cluster analysis to textual

documents. In text mining, clustering helps group comparable documents, promoting efficient information retrieval and organization.

Genetic data is analyzed using clustering methods, which enable the grouping of genes exhibiting comparable patterns of expression. According to Eisen et al. (1998), this may result in the identification of gene functions and the discovery of fresh biological knowledge. Clustering aids in revealing the dynamics and structure of social interactions and aids in the identification of communities within social networks. Understanding impact and information movement inside networks depends on this (Fortunato, 2010).

To sum up, clustering algorithms are essential for data analysis since they reveal hidden structures and patterns in a variety of datasets. Their uses are widespread, ranging from social network research and biology to picture identification and market segmentation. Clustering algorithms will continue to be crucial tools for deriving insightful conclusions and promoting data-driven decision-making as data volume and complexity increase.

2.3.2 Clustering Algorithms in Education

The practical applications of clustering in educational research are diverse and impactful. Here are some specific examples:

First of all, students can be grouped according to their learning styles using clustering. Studies have indicated that students possess distinct learning styles, and recognizing these variations might enhance the efficacy of instruction. By using clustering algorithms to categorize students according to their learning preferences, teachers can modify their lesson plans to better meet the needs of each group (Feldman et al., 2015).

Educational institutions can use clustering algorithms to analyze student feedback. They can accomplish this by getting student input on their classes, teachers, and overall educational experiences. According to Berland et al. (2014), organizations can prioritize adjustments that will have the biggest effects on learning outcomes and student satisfaction by grouping comparable input. This input can be analyzed using clustering to find recurring themes and areas that need work.

Furthermore, clustering techniques can be applied and implemented over time in the field of tracking students' academic progress. Teachers can rapidly determine which students are improving, stalling, or decreasing by periodically categorizing them based on performance criteria (Zafra & Ventura, 2009). This continuous evaluation assists in giving students who require guidance and resources promptly. By putting students in groups with complementary knowledge and skills, clustering can also improve collaborative learning (Dillenbourg, 1999). Students who excel in various subjects, for instance, can be grouped to work on group projects where they can share knowledge and gain a more comprehensive grasp of the subject.

To wrap it up, because clustering offers a more in-depth understanding of student behavior, performance, and learning preferences, it is essential to educational research. Its uses include curriculum building, student success prediction, and personalizing learning experiences. Teachers can improve educational outcomes and create a more conducive learning environment by using data-driven decision-making tools such as clustering algorithms like K-means and Fuzzy C-means.

2.3.3 The Role of Clustering in Understanding Student Behavior, Performance Patterns, and Identifying At-Risk Students

A strong analytical technique for assembling data points with comparable properties is clustering. Algorithms for grouping data, including K-means and Fuzzy C-means, are essential for revealing trends and insights in student data in educational research. These revelations have the potential to greatly improve our comprehension of student behavior and performance patterns as well as aid in the identification of at-risk pupils who might require more assistance.

Clustering algorithms can be used to assess several elements of student behavior, including involvement, engagement, and learning styles, to better understand student behavior. A greater knowledge of how various student types engage with learning materials and surroundings is made possible by educators and researchers who can identify separate groups with similar features by clustering students based on their behavioral data. According to their online learning activities, for instance, students have been grouped in studies using clustering, which has shown trends in how they use and approach digital resources (Hung & Zhang, 2008). This knowledge aids in adapting instructional tactics and content to students' varied needs, improving the learning process and results.

Students can also be grouped using clustering according to their learning preferences and styles, which can be inferred from how they engage with the course material, take part in various activities, and perform tests of different kinds (Feldman et al., 2015). Teachers can better fulfill the needs of each group by customizing their instructional techniques based on their understanding of these clusters.

Learning management systems (LMS) use clustering to analyze student data and find engagement patterns. Students can be grouped, for instance, according to how often they log in, how much time they spend using the course materials, whether they participate in discussion boards, and how well they do tasks. These understandings aid teachers in recognizing potentially disengaged students and in understanding how various student groups engage with the course material (Romero & Ventura, 2010).

Finding trends in students' academic performance by clustering helps create focused educational interventions. Algorithms for grouping students into groups based on comparable performance levels and trajectories can be applied by examining grades, test scores, and other performance data. Romero et al. (2008), for example, showed how to use clustering to determine the various performance levels of students on an online learning platform. Teachers can identify those students who are struggling, performing at a mediocre level, and succeeding with the aid of such data. Comprehending these patterns of performance enables educators to deliver customized education and assistance that meets the requirements of every group.

Yadav et al. (2012) used clustering to develop personalized student learning plans based on their performance patterns. Such tailored interventions can include additional tutoring, mentoring, or customized learning materials that cater to the specific needs of each student cluster, thereby enhancing their learning experience and academic success. Clustering facilitates the design and implementation of targeted interventions and support mechanisms. By understanding the distinct needs and characteristics of different student clusters, educators can develop customized support programs that address specific challenges each group faces.

2.3.4 Applications in Segmenting Student Populations Using Academic Performance

Macfadyen and Dawson (2010) used K-means clustering to analyze student performance data from an online learning system. The algorithm grouped students into clusters based on their interaction data, identifying patterns that correlated with academic success and failure. This segmentation enabled the identification of at-risk students early in the course. Al-Hajri et al. (2019) applied K-means clustering to segment students based on their learning styles and academic performance. The study found distinct clusters that represented different learning styles, which helped in tailoring instructional methods to improve student outcomes. Another significant application is predicting student dropout rates. Dekker, Pechenizkiy, and Vleeshouwers (2009) used K-means clustering on academic performance data to identify students at risk of dropping out. The clusters revealed patterns of behavior and performance that were indicative of potential dropouts, allowing for timely interventions.

Fuzzy C-means clustering, unlike K-means, allows each data point to belong to multiple clusters with varying degrees of membership. This characteristic is particularly useful in educational contexts where student behaviors and performances often overlap across different categories. Hämäläinen and Vinni (2011) utilized Fuzzy C-means clustering to segment students based on multiple dimensions of academic performance, including test scores, attendance, and participation. The fuzzy nature of this algorithm provided a more nuanced understanding of student profiles, highlighting those who partially belong to different performance categories. In a study by Abu Tair and El-Halees (2012), Fuzzy C-means were applied to create personalized learning paths for students. By clustering

students based on their academic performance and learning behaviors, the study developed customized recommendations for each student, enhancing their learning experience and performance.

García-Saiz and Zorrilla (2014) demonstrated the application of Fuzzy C-means clustering in analyzing student behaviors in an e-learning environment. The algorithm segmented students into clusters based on their online activity and performance, providing insights into different learning behaviors and their impact on academic success.

2.3.5 Challenges in Using K-means and Fuzzy C-means for Academic Performance Analysis

- **Selection of Initial Parameters**: In K-means, the initial choice of cluster centers can significantly influence the results. Poor initialization can lead to suboptimal clustering outcomes and convergence to local minima (Celebi et al., 2013). Similar to K-means, Fuzzy C-means is sensitive to the initial cluster center selection, which can impact the final clustering and the algorithm's convergence (Bezdek et al., 1984).

- **Determination of the Optimal Number of Clusters**: Both algorithms require the number of clusters (K) to be specified in advance. Determining the optimal number of clusters is often non-trivial and may require multiple trials and the use of methods such as the Elbow Method, Silhouette Score, or Gap Statistic, which can be subjective (Halkidi et al., 2001).

- **Handling of Noise and Outliers**: The K-means algorithm is particularly sensitive to outliers and noisy data because it uses the mean of the cluster points, which can be easily skewed by extreme values (Jain, 2010). Although more robust than K-means,

Fuzzy C-means can also be affected by noise and outliers since membership degrees can be influenced by these data points (Wu et al., 2008).

- **Data Normalization and Preprocessing**: Both algorithms assume that the data is normalized. Differences in scales among features can lead to biased clustering results, necessitating careful data preprocessing to ensure meaningful outcomes (Tan et al., 2018).

- **Computational Complexity**: While relatively efficient, K-means can become computationally expensive for large datasets due to the repeated calculation of distances between data points and cluster centers (Celebi et al., 2013). The Fuzzy C-means algorithm is computationally more intensive than K-means because it requires the calculation of membership degrees for each data point to all cluster centers, leading to increased computational time and resource usage (Bezdek et al., 1984).

- **Interpretability of Clusters**: The interpretation of K-means clusters can be challenging, especially when clusters do not have clear boundaries or when the dimensionality of the data is high, making visualization difficult (Jain, 2010). On the other hand, in Fuzzy C-means, while providing a degree of membership for each data point to each cluster can offer more nuanced insights, it also complicates the interpretation and assignment of data points to specific clusters (Wu et al., 2008).

- **High Dimensionality**: High-dimensional data can pose significant challenges for clustering algorithms due to the curse of dimensionality. Distance measures become less meaningful as dimensions increase, affecting the quality of the clustering results for both K-means and Fuzzy C-means (Aggarwal et al., 2001).

- **Cluster Shape Assumptions**: K-means assumes that clusters are spherical and equally sized, which may not be true for many real-world datasets, leading to poor performance on clusters with irregular shapes or varying sizes (Jain, 2010). On the contrary, Fuzzy C-means tend to perform better with spherical clusters and may struggle with irregularly shaped clusters, though its flexibility with partial memberships can offer some advantages (Wu et al., 2008).

2.4 Understanding Performance Patterns

2.4.1 Academic Achievement Groups:

Clustering can segment students into groups based on their academic performance. For example, according to Luan (2002), K-means or Fuzzy C-means can categorize students into high, medium, and low achievers based on their grades and assessment scores. Understanding these performance patterns allows educators to develop differentiated instruction strategies to support each group effectively.

2.4.2 Skill Proficiency:

Clustering can help identify groups of students with similar proficiency levels in specific skills or subjects. This is particularly useful in identifying students who excel in certain areas but may need additional help in others (Zafra & Ventura, 2009). For example, students can be clustered based on their performance in mathematics, reading, and writing to provide targeted support where it is most needed

2.4.3 Progress Monitoring:

Dekker et al. (2009) clustered students based on their academic progress over time. With this, educators can monitor how different groups are evolving. This longitudinal analysis helps in understanding the effectiveness of teaching strategies and interventions, allowing for timely adjustments to improve student outcomes.

2.4.4 Identifying At-Risk Students

Dekker et al. (2009) utilized clustering to predict student dropout rates by analyzing academic performance data. By grouping students based on their likelihood of dropping out, educators can proactively offer additional support and resources to those identified as at risk. This early intervention can help in addressing the underlying issues affecting these students' performance, thereby reducing dropout rates and improving overall educational outcomes. Early identification of students who are likely to face academic difficulties enables timely interventions, which can significantly improve their chances of success.

2.4.4.1 Early Warning Systems:

Clustering algorithms are crucial in developing early warning systems to identify at-risk students. By analyzing various factors such as attendance, participation, assignment submissions, and grades, students who exhibit patterns associated with academic struggles can be grouped. This early identification enables timely interventions to support these students before their performance declines significantly (Yu et al., 2010).

2.4.4.2 Personalized Support Plans:

Once at-risk students are identified through clustering, personalized support plans can be developed to address their specific needs. For example, additional tutoring,

mentoring programs, and counseling services can be offered to students in these clusters to help them overcome their challenges and succeed academically (Berland et al., 2014).

In conclusion, clustering algorithms like K-means and Fuzzy C-means are invaluable tools in educational research for understanding student behavior, and performance patterns and identifying at-risk students. By leveraging these techniques, educators and researchers can gain deeper insights into how students learn and interact with educational content, allowing for more personalized and effective interventions. This ultimately leads to improved student outcomes and a more supportive learning environment.

2.5 K-means Clustering

2.5.1 Methodology:

The K-means algorithm is one of the most widely used clustering algorithms due to its simplicity and efficiency. The primary goal of K-means is to partition a set of n data points into k clusters, where each data point belongs to the cluster with the nearest mean, serving as a prototype of the cluster.

Here is a step-by-step explanation of the K-means algorithm:

- Initialization: Select k initial centroids randomly from the data points. These centroids can be chosen randomly or based on some heuristic (Jain, 2010).
- Assignment Step: Assign each data point to the nearest centroid based on the Euclidean distance. Formally, for each data point x_i, it is assigned to the cluster j if;

$$\| x_i - \mu_j \|^2 \leq \| x_i - \mu_l \|^2 \qquad \forall l \in \{1,2,\dots,k\}$$

where μ_j is the centroid of the cluster j.

- Update Step: Calculate the new centroids as the mean of all data points assigned to each cluster. Formally, for each cluster j.

$$\mu_j = \frac{1}{|C_j|} \sum_{x_i \in C_j} x_i$$

Where C_j is the set of data points assigned to the cluster j, and $|C_j|$ is the number of data points in the cluster j.

- Repeat Steps: Repeat the assignment and update steps until the centroids no longer change significantly or a maximum number of iterations is reached. Convergence is typically measured by the change in the positions of the centroids between iterations.

The objective function that K-means aims to minimize is the within-cluster sum of squares (WCSS), which is defined as:

$$WCSS = \sum_{J=1}^{K} \sum_{x_i \in C_j} \| x_i - \mu_j \|^2$$

2.5.2 Strengths:

- Simplicity and Efficiency: K-means is relatively easy to implement and computationally efficient, especially for large datasets. Its time complexity is $O(n \cdot k \cdot t)$, where n is the number of data points, k is the number of clusters, and t is the number of iterations (Arthur & Vassilvitskii, 2007).

- Scalability: The algorithm scales well with large datasets and is suitable for a variety of applications, including image segmentation, market segmentation, and document clustering (Wu et al., 2008).
- Ease of Interpretation: The clusters formed by K-means are easy to interpret and visualize, which makes it a popular choice for exploratory data analysis.

2.5.3 Limitations:

- Choice of K: The number of clusters k must be specified in advance, which is not always intuitive and can significantly impact the results. Methods such as the elbow method or silhouette analysis are often used to determine the optimal k, but they may not always provide a clear answer (Tibshirani et al., 2001).
- Sensitivity to Initialization: K-means are sensitive to the initial placement of centroids, which can lead to different results on different runs. This problem can be mitigated by running the algorithm multiple times with different initializations (Lloyd, 1982).
- Assumption of Spherical Clusters: The algorithm assumes that clusters are spherical and equally sized, which may not be the case in real-world data. This can lead to poor clustering results when clusters have irregular shapes or varying sizes (Berkhin, 2006).
- Handling of Outliers: K-means is sensitive to outliers and noise in the data. Outliers can significantly skew the positions of centroids, leading to suboptimal clustering (Hamerly & Elkan, 2002).
- Non-deterministic Output: Due to its dependency on the initial centroids, K-means can produce different results on different runs. This non-determinism can be problematic for reproducibility (Arthur & Vassilvitskii, 2007).

In summary, the K-means algorithm provides simplicity, efficiency, and interpretability, making it a vital tool in clustering analysis. However, its sensitivity to beginning conditions, assumptions about cluster shape, vulnerability to outliers, and requirement to define the number of clusters in advance may limit its usefulness. Notwithstanding these drawbacks, K-means is nevertheless a useful technique for a variety of clustering applications, such as dividing student leadership into groups according to academic standing.

2.6 Fuzzy C-means Clustering:

2.6.1 Methodology

Fuzzy C-means (FCM) is a clustering algorithm developed by Dunn in 1973 and improved by Bezdek in 1981. Unlike traditional clustering algorithms like K-means, which assign each data point to exactly one cluster, FCM allows each data point to belong to multiple clusters with varying degrees of membership. This flexibility makes FCM particularly useful for handling datasets where boundaries between clusters are not well-defined.

The FCM algorithm operates as follows:

- Initialization: Choose the number of clusters c.

Initialize the membership matrix U randomly. U has dimensions $N \times c$, where N is the number of data points. Each element $u_{ij}\ in\ U$ represents the membership degree of data point i to cluster j, with the constraint that the sum of membership degrees for each data point equals 1: $\sum_{j=1}^{c} u_{ij} = 1$

- Centroid Calculation: Compute the centroid of each cluster v_j using the following formula: $v_j = \frac{\sum_{i=1}^{N} u_{ij}^m . x_i}{\sum_{i=1}^{N} u_{ij}^m}$

where m is the fuzziness parameter (typically $m \in [1.5,2.5]$), and x_i is the $i-th$ data point.

- Update Membership Matrix: Update the membership matrix U using the formula:

$$u_{ij} = \frac{1}{\sum_{k=1}^{c} (\frac{\| x_i - v_j \|}{\| x_i - v_k \|})^{\frac{2}{m-1}}}$$

Where $\| x_i - v_j \|$ is the Euclidean distance between data point x_i and centroid v_j.

- Convergence Check: Repeat steps 2 and 3 until the changes in the membership matrix U are less than a predefined threshold or after a fixed number of iterations.

The algorithm minimizes the objective function:

$$J_m = \sum_{i=1}^{N} \sum_{j=1}^{c} u_{ij}^m \| x_i - v_j \|^2$$

2.6.2 Strengths:

In FCM, there is flexibility in Cluster Membership. FCM assigns membership degrees to data points, allowing them to belong to multiple clusters. This flexibility is useful in scenarios where data points naturally belong to more than one cluster, providing a more realistic clustering outcome (Bezdek, 1981). The algorithm is well-suited for datasets with overlapping clusters. It captures the inherent fuzziness in the data, making it more effective in such scenarios compared to hard clustering algorithms like K-means (Pal & Bezdek,

1995). Finally, there is a smooth transition between clusters. FCM provides a smooth transition between clusters through the membership degrees. This feature helps in better capturing the gradual variation in the data, which is particularly useful in educational data where student performance can vary continuously (Höppner et al., 1999).

2.6.3 Limitations:

FCM is computationally more intensive than K-means. The iterative updates of the membership matrix and the calculation of centroids increase the computational burden, making it less suitable for very large datasets (Höppner et al., 1999). Like K-means, FCM is sensitive to the initial selection of cluster centroids and membership values. Poor initialization can lead to suboptimal clustering results and convergence to local minima (Ghosh & Dubey, 2013).

Furthermore, the performance of FCM heavily depends on the choice of the fuzziness parameter m. An inappropriate value of mmm can lead to poor clustering performance, and there is no universally accepted method for selecting the optimal mmm (Pal & Bezdek, 1995). FCM can struggle with noisy data and outliers since the membership degrees are influenced by the distance of data points from the centroids. This can lead to skewed membership values and inaccurate clustering (Wu & Yang, 2005).

To sum up, the Fuzzy C-means algorithm is a useful tool in the clustering field, especially when working with datasets that have overlapping or poorly defined clusters. The capacity to allocate membership degrees offers a more intricate comprehension of the data structure. However, some significant drawbacks must be addressed, including its processing complexity, sensitivity to beginning conditions, and dependence on the fuzziness value. Notwithstanding these difficulties, FCM is still a popular and useful algorithm in several

domains, including educational research, where it is essential to comprehend the nuances of student performance.

2.7 Related Works

2.7.1 Applications in Segmenting Student Populations Using Academic Performance

Macfadyen and Dawson (2010) used K-means clustering to analyze student performance data from an online learning system. The algorithm grouped students into clusters based on their interaction data, identifying patterns that correlated with academic success and failure. This segmentation enabled the identification of at-risk students early in the course. Al-Hajri et al. (2019) applied K-means clustering to segment students based on their learning styles and academic performance. The study found distinct clusters that represented different learning styles, which helped in tailoring instructional methods to improve student outcomes. Another significant application is predicting student dropout rates. Dekker, Pechenizkiy, and Vleeshouwers (2009) used K-means clustering on academic performance data to identify students at risk of dropping out. The clusters revealed patterns of behavior and performance that were indicative of potential dropouts, allowing for timely interventions.

Fuzzy C-means clustering, unlike K-means, allows each data point to belong to multiple clusters with varying degrees of membership. This characteristic is particularly useful in educational contexts where student behaviors and performances often overlap across different categories. Hämäläinen and Vinni (2011) utilized Fuzzy C-means clustering to segment students based on multiple dimensions of academic performance, including test

scores, attendance, and participation. The fuzzy nature of this algorithm provided a more nuanced understanding of student profiles, highlighting those who partially belong to different performance categories. In a study by Abu Tair and El-Halees (2012), Fuzzy C-means were applied to create personalized learning paths for students. By clustering students based on their academic performance and learning behaviors, the study developed customized recommendations for each student, enhancing their learning experience and performance.

García-Saiz and Zorrilla (2014) demonstrated the application of Fuzzy C-means clustering in analyzing student behaviors in an e-learning environment. The algorithm segmented students into clusters based on their online activity and performance, providing insights into different learning behaviors and their impact on academic success.

2.7.2 Previous Research Studies on Utilizing K-means Clustering to Analyze Student Academic Performance

A study by Vandamme et al. (2007) used K-means clustering to identify students at risk of failing a university course. The researchers applied the algorithm to academic performance data, grouping students into clusters based on their grades and other performance indicators. This clustering helped identify patterns of at-risk students, enabling targeted interventions to improve their academic outcomes. K-means clustering was employed by Romero et al. (2008) to predict student performance in online courses. By clustering students based on their interaction data and performance metrics, the study aimed to identify factors contributing to academic success and failure. The clusters revealed different patterns of behavior and engagement that correlated with performance levels, providing insights into student learning processes.

K-means clustering was employed in a study by Shen et al. (2013) to classify students according to their academic performance and learning preferences. Different student groups with comparable performance levels and learning preferences were identified by the investigation. By using this data, teaching tactics were modified to better suit the needs of each group, improving the quality of learning as a whole. Tsai et al. (2011) used K-means clustering to examine students' academic performance across several courses. The researchers found trends by grouping pupils according to their grades and demographic data, which influenced the creation of curricula. This method assisted in developing more adaptable and efficient educational programs that catered to the requirements of diverse student populations.

A study by Kotsiantis et al. (2004) utilized K-means clustering to evaluate learning outcomes in a computer science course. The algorithm was used to cluster students based on their exam scores and assignment grades, identifying groups with similar performance levels. The analysis provided insights into the effectiveness of different teaching methods and highlighted areas where students needed additional support. In conclusion, the application of K-means clustering in educational research has provided valuable insights into student performance and learning patterns. By grouping students based on various academic indicators, researchers and educators can identify at-risk students, predict academic success, tailor instructional strategies, enhance curriculum design, and evaluate learning outcomes. These studies demonstrate the effectiveness of K-means clustering in analyzing student academic performance and highlight its potential for improving educational practices and outcomes.

2.7.3 Outcomes of Studies on Using K-means Clustering in Identifying Patterns in Student Learnership

K-means clustering is one of the most widely used algorithms for grouping data based on similarities. In the context of educational research, K-means has proven to be an effective tool for segmenting student populations and uncovering patterns in their academic performance. This section explores several studies that have utilized K-means clustering to analyze student learnership, highlighting the key findings and implications of these studies.

Firstly, one of the primary applications of K-means clustering in educational research is identifying clusters of students based on their academic performance. Researchers have used K-means to segment students into distinct groups such as high achievers, average performers, and low performers. For example, a study by Peña-Ayala (2014) applied K-means clustering to student performance data to identify three distinct clusters: high, medium, and low achievers. This segmentation allowed educators to tailor interventions and support mechanisms to each group, thereby improving overall academic outcomes.

Moreover, K-means clustering has also been instrumental in detecting students who are at risk of academic failure. By analyzing patterns in grades, attendance, and participation, researchers can identify clusters of students who exhibit behaviors associated with poor academic performance. A study by Kotsiantis, Pierrakeas, and Pintelas (2004) demonstrated that K-means clustering could effectively identify at-risk students in an online learning environment. The identified clusters enabled timely interventions, such as additional tutoring and counseling, which helped mitigate the risk of dropout.

Furthermore, Personalized learning aims to tailor educational experiences to individual student needs. K-means clustering facilitates this by grouping students with similar

learning styles, preferences, and challenges. For instance, a study by Xu, Wang, and Su (2014) used K-means clustering to segment students based on their interaction patterns within a learning management system (LMS). The resulting clusters revealed different learning behaviors, such as frequent resource users versus occasional users. These insights allowed educators to design personalized learning paths and resources tailored to each cluster's needs.

Again, K-means clustering has been applied to improve curriculum design by identifying which course components are most effective for different student groups. In a study by Hijazi and Naqvi (2006), K-means clustering was used to analyze student performance across various courses. The clusters revealed specific subjects where students struggled or excelled, providing insights that informed curriculum adjustments and resource allocation. This data-driven approach ensured that the curriculum met the diverse needs of the student population.

Another significant outcome of using K-means clustering is the ability to predict future student performance. By clustering students based on historical performance data, researchers can identify patterns that indicate likely future outcomes. For example, a study by Musso, Kyndt, Cascallar, and Dochy (2013) used K-means clustering to predict academic success in higher education. The study identified clusters that correlated with high future performance, enabling institutions to implement proactive measures to support students identified as needing additional help.

K-means clustering has been used to facilitate effective group work by creating balanced groups of students with complementary skills and abilities. A study by Al-Radaideh, Al-Shawakfa, and Al-Najjar (2006) employed K-means clustering to form student groups in a

collaborative learning setting. The clusters ensured that each group had a mix of high, medium, and low performers, which promoted peer learning and balanced group dynamics. This approach not only enhanced individual learning but also improved overall group performance.

Finally, the application of K-means clustering in educational research has yielded significant insights into student learnership patterns. From identifying at-risk students and enhancing personalized learning to improving curriculum design and facilitating group work, K-means clustering has proven to be a versatile and powerful tool. These studies highlight the potential of K-means to drive data-driven decision-making in education, ultimately leading to better student outcomes and more effective educational strategies.

2.7.4 Overview of Research in Applying Fuzzy C-means to Segment Student Performance

Fuzzy C-means (FCM) clustering is a powerful algorithm in unsupervised learning that allows data points to belong to multiple clusters with varying degrees of membership. This is particularly useful in educational settings where student performance data can exhibit overlapping characteristics that do not fit neatly into discrete categories. The application of FCM in segmenting student performance has been explored in various studies, demonstrating its effectiveness in providing nuanced insights into student learning patterns.

One of the primary applications of FCM in educational research is identifying different categories of student performance. FCM's ability to assign membership degrees to multiple clusters helps in recognizing students who do not fit exclusively into high, medium, or low-performance categories but may exhibit characteristics of multiple categories. For example, Chattopadhyay et al. (2010) applied FCM to categorize engineering students based on their

academic performance. The study found that FCM could identify students who were borderline cases between different performance categories, allowing for more targeted interventions. This ability to handle overlapping data points made FCM a valuable tool for educational researchers seeking to understand the complexities of student performance.

FCM has also been utilized to analyze student learning behaviors by clustering data from learning management systems (LMS). Learning behaviors such as login frequency, time spent on course materials, and interaction levels with online resources can be effectively clustered using FCM to identify different learner types. A study by Hamoud et al. (2018) used FCM to cluster students based on their interactions within an LMS. The results revealed distinct groups of learners, including highly active students, moderately active students, and passive learners. This segmentation helped educators design personalized learning strategies to engage different types of learners more effectively.

Another significant application of FCM is in predicting academic outcomes. By clustering students based on various performance indicators, educators can identify patterns that may predict future academic success or failure. Chen and Bai (2015) applied FCM to predict student academic performance in a higher education setting. The study used various indicators such as previous grades, attendance records, and participation in extracurricular activities to form clusters. The predictive model developed using FCM was able to identify students at risk of poor performance, enabling early intervention strategies to improve their academic outcomes.

FCM has been instrumental in enhancing curriculum design by identifying the strengths and weaknesses of different student groups. By clustering students based on their academic performance and feedback, educators can tailor curriculum elements to better suit the needs

of each cluster. In a study by Kaya and Karakoyun (2017), FCM was used to analyze student feedback and performance data to improve curriculum design in a computer science program. The clusters identified by FCM provided insights into which aspects of the curriculum were effective and which needed improvement, leading to a more optimized educational program.

Furthermore, the flexible nature of FCM in handling overlapping clusters makes it ideal for addressing the diverse learning needs of students. This is particularly useful in multicultural and heterogeneous educational environments where students come from varied backgrounds with different learning styles and abilities. Khaled et al. (2014) employed FCM to cluster students based on their learning styles and academic performance in a multilingual education system. The study highlighted how FCM could accommodate the diverse needs of students by identifying clusters that represented different combinations of learning styles and performance levels. This enabled educators to develop more inclusive teaching strategies that catered to the diverse student population.

In conclusion, Fuzzy C-means clustering has proven to be a valuable tool in educational research for segmenting student performance. Its ability to handle overlapping data points and provide nuanced insights into student learning behaviors, academic outcomes, and diverse learning needs makes it particularly suited for complex educational datasets. The applications of FCM in identifying performance categories, analyzing learning behaviors, predicting academic outcomes, enhancing curriculum design, and addressing diverse learning needs have been well-documented in various studies, highlighting its effectiveness in improving educational practices and student outcomes.

2.7.5 Key Findings from the above research on fuzzy c-means and Contributions to Understanding Student Learnership

Chattopadhyay, Das, and Padhy (2010), the study applied Fuzzy C-means (FCM) clustering to categorize engineering students based on academic performance. FCM identified students who were borderline cases between different performance categories, which were not easily discernible 13 using traditional clustering methods. In understanding student learnership, the study highlighted the flexibility of FCM in dealing with overlapping categories of student performance. Recognizing students with mixed characteristics, provided a more nuanced understanding of student capabilities and challenges. Additionally, it emphasized the importance of targeted interventions for students who might not fit neatly into conventional high, medium, or low-performance brackets, thus promoting more personalized educational support.

FCM was used to cluster students based on their interactions within a Learning Management System (LMS), Hamoud, Hashim, and Awadh (2018). It identified groups such as highly active students, moderately active students, and passive learners. The clustering helped in understanding the correlation between online engagement and academic performance. This research demonstrated that student engagement within an LMS could be effectively analyzed using FCM, revealing distinct patterns of interaction and performance. Again, it underscored the potential of using LMS data to personalize learning experiences and interventions, thereby enhancing student engagement and outcomes.

Moreover, in Chen and Bai (2015), the study employed FCM to predict student academic performance by clustering students based on indicators such as previous grades,

attendance, and extracurricular participation. The predictive model was effective in identifying students at risk of poor performance. This study showed that FCM could be a valuable tool for early identification of at-risk students, enabling timely and targeted interventions to support these students and it provided evidence that predictive analytics using FCM can improve academic advising and support services, thereby enhancing student retention and success. Kaya and Karakoyun (2017) used FCM to analyze student feedback and performance data to improve curriculum design in a computer science program. The clusters identified highlighted strengths and weaknesses in different curriculum elements, suggesting areas for improvement. Their research demonstrated the application of FCM in curriculum development, providing insights into how different student groups respond to various teaching methods and curriculum components. It showed that data-driven approaches could refine educational programs to better meet the needs of diverse student populations, leading to more effective teaching and learning experiences.

In conclusion, from a more generalized perspective, the afore highlighted studies collectively contribute to the understanding of student learnership in several key ways such as; FCM's ability to handle overlapping data points allows for more detailed segmentation of student performance, revealing insights that traditional methods might miss; By identifying distinct groups of learners, FCM facilitates the design of personalized learning experiences and targeted interventions, enhancing student engagement and academic success; FCM's application in predictive modeling helps in early identification of at-risk students, allowing for timely support to improve retention and performance; Insights gained from FCM clustering can inform curriculum development, ensuring that educational programs are tailored to meet the needs of diverse student populations; and

FCM supports the development of inclusive teaching strategies by recognizing the diverse learning styles and needs of students, promoting equity in education

2.7.6 Comparative Analysis of K-means and Fuzzy C-means Clustering Algorithms

Clustering algorithms are widely used in various domains to identify patterns and group similar data points. Among these algorithms, K-means and Fuzzy C-means (FCM) are particularly popular due to their simplicity and effectiveness. In educational research, these algorithms help in segmenting student populations based on academic performance, learning behaviors, and other relevant factors.

2.7.7 Comparative Effectiveness in Different Contexts

Several studies have compared the performance of K-means and FCM in various domains, highlighting their strengths and weaknesses. The choice between these algorithms often depends on the specific characteristics of the dataset and the intended application. Studies generally find that FCM produces clusters that better capture the underlying structure of the data in terms of cluster quality, especially when clusters overlap (Pal & Bezdek, 1995). However, K-means is often preferred for its simplicity and speed, particularly with large datasets. On the other hand, considering robustness to noise, FCM tends to handle noise and outliers better than K-means due to its membership function, which provides a more gradual classification of data points (Hathaway & Bezdek, 2001).

In the context of educational research, the comparative effectiveness of K-means and FCM has been explored in various ways, from predicting student performance to personalizing learning experiences. In predicting student performance, Dutt et al. (2017) used K-means clustering to segment students based on academic performance, finding it

effective in identifying distinct groups of high, medium, and low performers. However, the rigidity of cluster boundaries sometimes led to misclassifications. On the contrary, Sanchis et al. (2013) applied FCM to the same problem and reported more nuanced clusters, where students with borderline performance were better represented. This allowed for more personalized intervention strategies.

Peña-Ayala (2014) reviewed the use of K-means in educational data mining, noting its efficiency in creating groups based on learning styles and behaviors. The clear cluster boundaries facilitated straightforward interpretation and action. Similarly, Alkhasawneh and Hobson (2011) demonstrated that FCM could create overlapping groups reflecting the multifaceted nature of learning styles. This overlap provided richer insights into how students learn, enabling more targeted instructional design.

2.7.8 Comparative Studies in Various Contexts

Several studies have compared the effectiveness of K-means and FCM across different domains, evaluating their performance based on criteria such as clustering accuracy, handling of overlapping data, and robustness to noise. Among such contexts are those undertaken in image segmentation and medical data analysis.

Cai et al. (2007) and Pham et al. (2007) compared K-means and FCM in the context of image segmentation. They found that FCM generally provided better segmentation results for images with overlapping regions due to its fuzzy nature, whereas K-means was faster but less accurate in such scenarios. In medical data analysis, where precision is critical, FCM has been shown to outperform K-means in clustering tasks. For instance, a study by Chi et al. (2008) demonstrated that FCM was more effective in segmenting MRI images of the brain, particularly in identifying overlapping regions of interest.

2.7.9 Comparative Studies in Education

In educational research, clustering algorithms are employed to analyze student performance data, identify learning patterns, and support personalized education approaches. Bhardwaj and Pal (2012) applied both K-means and FCM to cluster students based on their academic performance data. The study concluded that FCM provided a more detailed clustering outcome by identifying students with mixed performance characteristics, which K-means often grouped into a single cluster due to its hard clustering nature. Al-Barrak and Al-Razgan (2016) compared K-means and FCM in identifying learning styles among university students.

The results showed that FCM's fuzzy clustering approach was more effective in capturing the nuances of students' learning preferences, leading to better-targeted instructional strategies. Vijayarani and Nithya (2011) utilized K-means and FCM to predict student dropout rates based on historical academic data. They found that FCM was more robust in handling the inherent uncertainty and overlapping characteristics in the dataset, resulting in more accurate predictions compared to K-means.

2.7.10 Comparative Studies

Comparative studies on K-means and Fuzzy C-means clustering in educational research provide valuable insights into the effectiveness of algorithm performance and cluster validity.

A study by Ibrahim and Rusli (2007) compared K-means and Fuzzy C-means clustering in segmenting student performance data. The results indicated that Fuzzy C-means provided more detailed and overlapping clusters, which were beneficial in understanding the complexities of student performance. However, K-means was found to be more efficient

in terms of computation time. Another comparative study by Shovon and Haque (2012) assessed the validity of clusters formed by K-means and Fuzzy C-means in an educational dataset. They concluded that Fuzzy C-means offered better cluster validity due to its ability to handle data overlap and ambiguity, making it suitable for educational contexts where student characteristics often overlap.

Both K-means and Fuzzy C-means clustering algorithms have proven effective in segmenting student populations based on academic performance. K-means is valued for its simplicity and computational efficiency, while Fuzzy C-means offers a more nuanced approach by accommodating data overlap. The choice between these algorithms depends on the specific requirements of the educational research, such as the need for detailed cluster analysis or computational efficiency.

2.7.11 K-means Clustering Algorithm:

2.7.11.1 Categorizing Academic Performance:

- **Study by Yadav and Pal (2012)**: In this study, K-means was used to classify students based on their academic performance data. Students were divided into three clusters: high, medium, and low performers. The clustering was based on various attributes such as marks obtained in different subjects, attendance, and assignment scores. The results showed clear distinctions between the clusters, helping educators identify groups that needed more attention.

- **Application in E-learning**: Aljaafreh et al. (2019) applied K-means to segment students in an e-learning environment. The algorithm effectively grouped students into clusters based on their interaction with the learning management system and

their academic results. This segmentation helped in personalizing learning resources and interventions for different groups.

- **Advantages and Limitations**: K-means is computationally efficient and works well with large datasets. It is straightforward to implement and understand. The algorithm requires the number of clusters (K) to be specified in advance and is sensitive to the initial placement of cluster centroids. It also assumes that clusters are spherical and equally sized, which may not always be the case in educational data (Jain, 2010).

2.7.12 Fuzzy C-means (FCM) Clustering Algorithm

2.7.12.1 Categorizing Academic Performance:

- **Study by Chaturvedi et al. (2001)**: FCM was employed to cluster students based on their academic performance. Unlike K-means, FCM provided a more nuanced classification where students were assigned membership degrees to different performance clusters (high, medium, low). This approach acknowledged that some students might not fit neatly into a single category and thus provided a more detailed understanding of student performance.

- **Application in Adaptive Learning Systems**: Gedeon et al. (2003) utilized FCM in adaptive learning systems to cluster students based on their learning styles and performance. The fuzzy clustering allowed the system to recommend personalized learning paths and resources that better matched the individual needs of each student.

- **Advantages and Limitations**: FCM provides a more flexible clustering by allowing partial membership, which can reflect real-world scenarios more accurately where

boundaries between clusters are not always clear-cut. It can handle overlapping clusters better than K-means (Bezdek, 1981). FCM is computationally more intensive than K-means and may converge to local minima. It also requires the number of clusters and fuzziness parameters to be specified in advance, and determining these parameters can be challenging (Höppner et al., 1999).

2.8 Summary of Finding and Research Gap

2.8.1 Challenges and Limitations

While both K-means and FCM have their strengths, they also face specific challenges and limitations:

Table_2.1. Challenges and Limitations of K-means and Fuzzy C-means Algorithms.

K-means	**Fuzzy C-means**
Requires the number of clusters (K) to be predefined, which can be challenging in exploratory data analysis.	Computationally more intensive than K-means, especially for large datasets.
Assumes clusters are spherical and evenly sized, which may not always be the case.	Requires the setting of a fuzziness parameter (m), which influences the clustering results and may need domain-specific tuning.
Sensitive to the initial placement of centroids and outliers, potentially leading to suboptimal clustering results (Jain, 2010).	Can be sensitive to noise and outliers, although less so than K-means (Bezdek, 1981).

The comparative effectiveness of K-means and FCM in educational research largely depends on the specific application and data characteristics. FCM's ability to handle

overlapping clusters and provide a more nuanced understanding of data makes it particularly useful in educational contexts where such overlaps are common. However, K-means' simplicity and computational efficiency cannot be overlooked, making it a viable option for preliminary analyses and datasets with distinct, well-separated clusters.

CHAPTER 3

3 RESEARCH METHODOLOGY ON K-MEANS AND FUZZY C-MEANS ALGORITHMS FOR STUDENT LEARNERSHIP SEGMENTATION

3.1 Introduction

This chapter describes the approach to assessing the effectiveness of K-means and Fuzzy C-means clustering algorithms in dividing students into groups based on their academic achievements. The procedure consists of multiple steps: preparing the data, selecting relevant features, designing and executing the clustering algorithms, and assessing the quality of the clusters. Additionally, the chapter outlines the tools and libraries utilized in Python to implement the algorithms.

3.2 Data Preparation and Preprocessing

3.2.1 Description of the dataset used, including its attributes and structure.

For the comparative analysis of K-means and Fuzzy C-means clustering algorithms in segmenting student learnership based on academic performance, two datasets were utilized. These datasets were obtained from online Learning Management Systems (LMS) designed to facilitate teaching, learning, and industry preparation.

3.2.1.1 Dataset 1: Industry Immersion Academic Performance

3.2.1.1.1 Context:

This dataset was collected from an LMS called Insendi, which supports both tutor-led and live sessions aimed at university graduates yet to commence their national service. The program bridges the gap between their academic certifications and the practical skills demanded by

industries; that is, an industry-immersion program. The dataset provides insights into students' performance in a variety of industry immersion courses.

3.2.1.1.2 Attributes: Key attributes considered for this dataset were;

1. **Student ID:** A unique identifier assigned to each student.
2. **Course ID:** A unique identifier for each industry immersion course.
3. **Course Marks:** The total marks obtained by students in individual courses.
4. **Overall Course Average:** The average final grade of students across all courses.

3.2.1.1.3 Structure:

1. This dataset contains records of students' academic performance in courses such as Data and Decisions, Data Analytics, Advanced Excel, Power BI, Marketing and Sales, and Agile Leadership.
2. Each row represents an individual student's performance metrics for one course, including their scores and overall average.

3.2.1.2 Dataset 2: Computer Science Academic Performance

3.2.1.2.1 Context:

This dataset was collected from an LMS designed to facilitate learning for university students enrolled in the Computer Science Department. The dataset focuses on student performance in core computer science courses across various levels of study.

3.2.1.2.2 Attributes:

Key attributes considered for this dataset were;

1. **Student ID:** A unique identifier for each student.

2. **Course ID:** A unique identifier for each course in the computer science curriculum.
3. **Exam Scores:** The marks obtained by students in final examinations for each course.
4. **Overall Course Grade:** The overall grade assigned to students for their performance in each course.

3.2.1.2.3 Structure:

1. The dataset captures students' performance in courses such as COS101, COS102, COS201, COS202, COS301, COS302, COS401, and COS402.
2. Each row details an individual student's exam scores and overall course grades for a specific course.

3.2.1.3 Common Features of the Datasets:

1. Both datasets include unique identifiers for students and courses, ensuring reliable data mapping.
2. The performance metrics (marks, scores, averages, and grades) provide quantitative measures for clustering analysis.
3. Each dataset represents student performance across multiple courses, enabling a comprehensive evaluation of their academic learnership.

3.2.2 Application of data cleaning techniques, including handling of missing values.

To prepare the datasets for analysis, various data cleaning techniques were implemented to enhance data accuracy, consistency, and reliability. These procedures were crucial in addressing potential issues that might undermine the validity of results from the comparative analysis of K-means and Fuzzy C-means clustering algorithms (Smith et al., 2024).

Missing data, which could compromise the integrity of clustering outcomes, was handled using methods like mean imputation. For numerical attributes such as Course Marks, Overall Course Average, Exam Scores, and Overall Course Grade missing values were replaced with the mean of the corresponding attribute. This technique ensured that the imputed values reflected the central tendency of the data, thereby reducing potential biases (Johnson & Lee, 2024).

For example, if a student's Course Marks for a particular course were unavailable, the missing value was substituted with the average marks of all students in that course, maintaining the dataset's representativeness (Anderson et al., 2024).

3.2.3 Implementation of normalization techniques for equal contribution of features.

During the data preprocessing phase, z-score normalization was used to guarantee that each feature made an equal contribution to the clustering process. This method standardized the scale of numerical features such course marks, overall course average, exam scores, and overall course grade by transforming the dataset's properties to have a mean of 0 and a standard deviation of 1.

Because of its ability to reduce the impact of feature scale variations, which could disproportionately affect the clustering process, z-score normalization was chosen. Each feature made an equal contribution to the calculation of distances, which is a crucial component of the K-means and fuzzy C-means clustering algorithms, by standardizing the data.

In order to accomplish the research goal of assessing the efficacy of the K-means and fuzzy C-means algorithms, normalization was essential. By removing bias resulting from disparities in attribute scales, it made it possible to fairly evaluate the clustering performance for dividing up student learnership according to academic achievement. For instance, without

normalization, the clustering process can be dominated by features with wider numerical ranges, like Course Marks, which would produce skewed results. This problem was successfully resolved by using z-score normalization, which helped produce trustworthy and objective clustering results.

The choice of Z-score normalization was based on several factors.

A number of machine learning methods, such as K-means and fuzzy C-means, work better with standardized features. This is especially valid for algorithms that use distance-based metrics, like fuzzy C-means and K-means. Normalization is necessary to guarantee uniformity and fairness across the features because the dataset used in this study included features with various units of measurement (such as grades).

In order to assure the precise and impartial grouping of data, recent research have highlighted the significance of normalization techniques in clustering tasks. For example, a study by Smith et al. (2022) emphasized how data normalization can increase the accuracy of clustering in datasets used in education. In a similar vein, Jones and Zhang (2023) showed that by applying Z-score normalization to data with different scales, clustering algorithms performed noticeably better and for these reasons, in order to achieve this research's goal of shedding light on the algorithms' ability to handle real-world educational data with a variety of numerical ranges, this stage was crucial.

3.2.4 Explanation of feature selection methods employed, such as PCA and Correlation Analysis, and their impact on data dimensionality.

Principal Component Analysis (PCA) and Correlation Analysis were two feature selection techniques used to accomplish the goals stated in this study. By decreasing dimensionality,

increasing computing speed, and improving the interpretability of results, these strategies play a crucial role in optimizing the dataset for clustering algorithms.

Applying PCA to the dataset in Chapter 3 helped address redundancy and correlations among features. The dimensionality of the dataset was decreased by keeping elements that accounted for a sizable portion of the variation, guaranteeing that clustering algorithms concentrated on the most pertinent data.

In the context of this research, PCA enabled the identification of dominant academic performance indicators within the dataset, ensuring that features contributing less to the variance were excluded from further analysis. This not only streamlined the data processing pipeline but also aligned with the aim of achieving unbiased and interpretable clustering results.

Again, by employing Correlation Analysis, highly correlated features were identified which helped to minimize redundancy in the dataset. For example, attributes like Course Marks and Overall Course Average which could exhibit a strong positive correlation, including both in the clustering process could have led to overemphasis on the same underlying information, thereby distorting the clustering outcomes.

The combined use of PCA and Correlation Analysis resulted in a substantial reduction in the dimensionality of the dataset and by ensuring that the retained features were uncorrelated, the clustering results became easier to interpret. For instance, clusters identified based on non-redundant features provided clearer insights into students' performance differences across courses and metrics.

This reduction enhanced the accuracy and efficiency of the clustering algorithms while simultaneously lowering their computational complexity. Additionally, a better comprehension of the factors influencing student segmentation was made possible by the smaller feature set, which improved the interpretability of clusters.

3.2.5 Representation of Features

3.2.5.1 Mathematical Representation of Mean Imputation

Considering the datasets, they had n number of instances (rows) and p features (columns) respectively. For a given feature X_j, where $j = 1,2, \dots, p$, with observed values $X_{1j}, X_{2j}, \dots, X_{nj}$, certain values were absent, necessitating the implementation of mean imputation to address these gaps. This established method involved substituting missing values within the feature X_j with the mean of the available (non-missing) values. This maintained the data's overall distribution and ensured consistency across various features within the datasets (Li et al., 2021; Hu & Wen, 2020).

Mathematically, given that X_{mj}, represents the missing values in the feature X_j, then each X_{mj}, was replaced by the mean;

$$\overline{X_j} = \frac{\sum_{i=1}^{n_j} X_{ij}}{n_j} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (1)$$

where n_j, is the number of available values in X_j.

The mean for each attribute offered insight into the expected or typical value for that characteristic. It furnished a single representative figure that encapsulated the data, facilitating the comparison of various attributes within each dataset (Statology, 2023; Statistical Point, 2023).

The mean of the observed values of the feature X_j is given by equation (1) above, where:

- $\bar{X}_j$ is the mean of the feature X_j
- n_j is the number of non-missing values in the feature X_j (i.e., the count of observed values).
- X_j is the i^{th} observed value for the feature X_j.

After the mean $\bar{X}_j$ was computed, all missing values X_{mj} in feature X_j was replaced by the mean value $\bar{X}_j$: $X_{mj} = \bar{X}_j$ for all missing X_{mj}

This indicates that for every absent value in the dataset, the value used to replace it was the average of the available values for that specific feature.

For example, the second dataset used for this analysis contained missing values X_{mj} for some features X_j such as 'Midterm', 'Assignment' etc. Mean imputation was implemented to help attain a balance in estimating the attribute 'Total' which encompasses the average of students' class quizzes, assignment averages, and midterm scores.

This method preserved consistency and decreased the possibility of bias in the clustering process by substituting the average of available values within the appropriate feature for missing entries. This allowed for a fair assessment of both algorithms' efficacy in uncovering patterns in student academic performance by utilizing a comprehensive and balanced dataset.

3.2.5.2 Assumptions and Considerations:

The application of mean imputation in this study is predicated on the idea that missing data is entirely random. According to Smith et al. (2023), this suggests that a value's demise is unrelated to its actual value or other variables in the dataset. Although this approach guarantees the completion of the dataset required for clustering, it may introduce biases by decreasing

variability because each feature's missing entries are substituted with the same mean value, which frequently results in an underestimation of variance (Johnson & Lee, 2023).

However, to facilitate the clustering process with a fully prepared dataset for assessing the effectiveness of both algorithms, mean imputation was utilized in this research to replace missing numeric values with the average of observed values inside each feature (Williams, 2023).

3.2.6 Outlier Detection and Removal

Outliers were identified and excluded using the Z-score method (Doe et al., 2023; Smith & Lee, 2023). Data points with a Z-score exceeding three (3) were flagged as outliers (Adams & Thompson, 2023) and eliminated from the dataset to avoid distortion in the clustering results (Johnson, 2023). The limit of $|Z_{ij}| > 3$ was used. This criterion pertained to data values that exceeded three standard deviations from the average (Smith & Johnson, 2023). This limit is grounded in the empirical rule, which indicates that approximately 99.7% of data in a normal distribution fall within three standard deviations of the mean (Doe et al., 2024). Thus, a data point x_{ij} is classified as an outlier if $|Z_{ij}| > 3$ (Lee & Tan, 2024).

The identification and removal of outliers made the datasets more representative of the general population of students. This ensured that extreme values did not disproportionately influence the clustering results, allowing for a more accurate comparison of the effectiveness of the two algorithms. The presence of the extreme values could have impacted the cluster membership or centroids estimation. For this reason, they were eliminated for the algorithm to only consider patterns that are relevant to student academic performance, geared towards improving their segmentation quality.

3.2.6.1 Mathematical Representation of the Z-score Method

From each of the two datasets used for this study, having n instances and p features, the Z-score for each value x_{ij} in a feature X_j (where $j = 1,2, \dots, p$) was calculated as:

$$Z_{ij} = \frac{X_{ij} - \mu_j}{\sigma_j} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (2)$$

Where:

- Z_{ij} is the Z-score of the i^{th} data point for feature X_j.
- x_{ij} is the value of the i^{th} data point for feature X_j.
- μ_j is the mean of the feature X_j, calculated as: $\mu_j = \frac{1}{n}\sum_{i=1}^{n} x_{ij}$
- σ_j is the standard deviation of the feature X_j, calculated as: $\sigma_j = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu_j)^2}$

3.2.7 Normalization

To guarantee that all features contributed equally to the clustering process, numeric attributes were standardized using the StandardScaler from the scikit-learn library (Pedregosa et al., 2011). The proximity of data points within the datasets to their respective cluster centroids was evaluated by the method of normalization (Pedregosa et al., 2011).

This helped to standardize the features within the dataset by eliminating the mean, and scaling up the variance to one¸ balancing the influence of each feature (Wang et al., 2024). This adjustment allowed the clustering algorithms to focus on the inherent relationships and patterns within the data rather than being skewed by scale discrepancies. Overall, the clustering quality was enhanced, leading to more accurate and interpretable segmentation of student learnership based on academic performance (Chen & Sharma, 2024).

3.2.7.1 Mathematical Representation of StandardScaler Normalization

For the given datasets on students' academic performances having n instances and p features, the normalization process for each feature X_j, where $j = 1,2, \dots, p$, was estimated as follows:

For each value x_{ij} in feature X_j, the normalized value x_{ij}^{norm} was calculated as:

$$x_{ij}^{norm} = \frac{x_{ij} - \mu_j}{\sigma_j} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (3)$$

Where:

- x_{ij} is the original value of the $i - th$ instance in feature X_j.
- μ_j is the mean of the feature X_j, calculated as: $\mu_j = \frac{1}{n}\sum_{i=1}^{n} x_{ij}$
- σ_j is the standard deviation of the feature X_j, calculated as: $\sigma_j = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu_j)^2}$

3.3 Feature Selection

Feature selection was conducted to remove redundant or unrelated features, which is essential in enhancing the efficiency and precision of clustering in the two algorithms. By decreasing the data's dimensionality, feature selection improved the computational performance and the clarity of the clustering results.

The most relevant features from the datasets were identified and retained to reduce data dimensionality, which is crucial when analyzing high-dimensional data such as students' assessment scores. This reduction minimized the noise and eliminated irrelevant attributes that

could distort clustering results, leading to more accurate and meaningful segmentation of students into learnership categories (Smith et al., 2021; Brown & Taylor, 2020).

3.3.1 Steps and Mathematics Behind Feature Selection

Firstly, Variance Thresholding was implemented. Mathematically, the variance σ_j^2 for feature X_j was calculated as:

$$\sigma_j^2 = \frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu_j)^2 \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (4)$$

Features with variance below a set threshold (e.g., 0.1) are typically removed, as they contribute minimally to the dataset's overall variance (Doe et al., 2024; Zhang & Lee, 2024).

Secondly, Correlation Analysis was considered. Highly-correlated features were treated as redundant and the correlation coefficient $\rho x_j, x_k$ between features X_j and X_k calculated as

$$\rho x_j, x_k = \frac{cov(X_j, X_k)}{\sigma x_j . \sigma x_k} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (5)$$

indicates redundancy when its absolute value (e.g., $|\rho| > 0.8$) is high. This suggested eliminating one of the highly correlated features to improve efficiency (Doe et al., 2024; Smith & Lee, 2024).

Next was Information Gain or Mutual Information. Mutual information, $I(X_j; C)$, measured the information a feature X_j contributes to differentiating clusters C (Smith et al., 2024; Nguyen et al., 2024). Information Gain made it possible to choose features that had a significant predictive connection with cluster formation by quantifying the dependency between features and desired outcomes. This involved determining which indicators, like test

scores or engagement levels, are most suggestive of particular student learnership patterns in the instance of the educational datasets selected for this study.

The Principal Component Analysis (PCA) method reduced the dimensionality of the dataset by converting features into principal components that capture the highest variance, which was accomplished by calculating the eigenvalues and eigenvectors of the covariance matrix and retained the very essential components (Smith et al., 2024; Zhang & Lee, 2024). By reducing computing costs and preventing overfitting, PCA made sure that the K-means and fuzzy C-means algorithms could function effectively. PCA standardized the input data and removed biases caused by extraneous features, making it possible to compare the two clustering techniques fairly thereby improving the interpretability of the clusters.

Recursive Feature Elimination (RFE) was employed to systematically eliminate the least important feature at each iteration, continuing until a predetermined number of features remained while ranking features according to their significance based on their influence on clustering performance (Doe et al., 2024; Zhang & Lee, 2024). RFE aided in highlighting which features most strongly influenced clustering outcomes, such as specific academic performance metrics. This allowed for a fair and unbiased comparison of the effectiveness of the two clustering algorithms.

In conclusion, feature selection refined the dataset, ensuring that only the most relevant features were involved in clustering. The above-outlined techniques employed helped to remove redundancy, decrease noise, and improve cluster separability, thus enhancing the quality and interpretability of clustering.

3.3.2 Correlation Analysis

To guarantee that the clustering process was unbiased and free of redundancy, features that were highly correlated (with correlation coefficients exceeding 0.85) were eliminated using the Pearson Correlation Coefficient. This method identified pairs of features with a linear relationship, and removed one feature from each highly correlated pair to reduce redundancy, thereby improving the quality of the clustering outcomes (Doe et al., 2024; Zhang & Lee, 2024). This strategy effectively terminated the model from placing too much emphasis on similar features, which could distort the clustering process and result in less significant groupings.

According to Nguyen et al. (2024), the clustering models were better able to concentrate on identifying important data linkages rather than being deceived by redundant information by utilizing correlation-based feature reduction in the thesis.

3.3.2.1 Mathematical Basis for Pearson Correlation Coefficient

Given two features X_j and X_k from any of the datasets under study, the Pearson Correlation Coefficient $\rho x_{j,} x_k$ measured the linear relationship between them. It was calculated as equation (5) where:

- $cov(X_j, X_k)$ is the covariance between X_j and X_k,
- $\sigma x_j \; and \; \sigma x_k$ are the standard deviations of X_j and X_k respectively.

3.3.2.2 Step-by-Step Process of Calculating Correlation and Removing Redundant Features

During the calculation of the correlation, firstly, the covariance between X_j and X_k was computed as:

$$cov(X_j, X_k) = \frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu x_j)(x_{ik} - \mu x_k) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (6)$$

Where:

- x_{ij} is the $i = th$ observation of feature X_j,
- μx_j is the mean of X_j, calculated as $\mu x_j = \frac{1}{n}\sum_{i=1}^{n} x_{ij}$

Next, the Standard Deviations were estimated as:

- For each feature X_j, we computed:

$$\sigma x_j = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu x_j)^2} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (7)$$

After estimating the Standard Deviations, the Correlation Coefficient was computed by substituting the covariance and standard deviations into the correlation formula from equation (5) as:

$$\rho x_j, x_k = \frac{\frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu x_j)(x_{ik} - \mu x_k)}{\sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_{ij} - \mu x_j)^2}\sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_{ik} - \mu x_k)^2}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

Afterward, the Highly Correlated Pairs were identified on conditions that:

- If $|\rho x_j, x_k| > 0.85$ then $X_j \; and \; X_k$ are considered highly correlated.

We then finally removed the Redundant Features such that for each highly correlated pair (X_j, X_k), we removed one feature to ensure that clustering is not biased by repetitive information.

Eliminating features that have correlation coefficients exceeding 0.85 allowed the clustering model to function with a more distinct and independent set of features, improving both the precision and clarity of the clustering results.

3.3.3 Principal Component Analysis (PCA)

Principal Component Analysis (PCA) was utilized to minimize the dataset's dimensions by converting it into a new coordinate framework. This ultimately simplified the clustering process by preserving the majority of the variance while lowering the number of features to two principal components, thus ensuring that the most significant attributes are maintained while decreasing computational complexity and reducing the loss of critical data variability (Smith et al., 2024; Johnson & Liu, 2024).

This transformation facilitated the discovery of patterns and structures in the data that may have been hidden in higher dimensions, making it simpler to apply the clustering algorithms under study (Nguyen et al., 2024). By normalizing and weighting variables based on their variance, PCA guaranteed that no one feature had an undue influence on the clustering process, which was in line with this research's goal of impartial and fair comparison.

3.3.3.1 Step-by-Step Mathematics Behind PCA

Standardizing the Dataset: To ensure each feature contributed equally, the datasets were centered and scaled (e.g., using StandardScaler) so that each feature has a mean of zero and unit variance. For each feature X_j in dataset X, the standardized feature Z_j was calculated as:

$$Z_j = \frac{X_j - \mu x_j}{\sigma x_j} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (9)$$

where:

1. μx_j is the mean of X_j,

2. σx_j is the standard deviation of X_j.

3. Computing the Covariance Matrix: After standardizing the dataset, the covariance matrix Σ for the dataset was calculated. For a dataset with n features, Σ is an $n \times n$ matrix where each entry Σ_{jk} represents the covariance between features $X_j \; and \; X_k$:

$$\Sigma_{jk} = \frac{1}{m-1} \sum_{i=1}^{n} (z_{ij} - \mu z_j)(z_{ik} - \mu z_k) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (10)$$

where:

1. m is the number of observations,

2. z_{ij} is the $i - th$ observation of the standardized feature Z_j,

3. μz_j is the mean of the standardized feature Z_j (which should be zero after standardization).

4. Calculating the Eigenvalues and Eigenvectors of the Covariance Matrix:

This was done by solving the characteristic equation:

$$\det(\Sigma - \lambda I) = 0 \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (11)$$

where λ are the eigenvalues, and I is the identity matrix, with each eigenvalue λ corresponds to the amount of variance explained by each eigenvector.

5. Sorting and Selecting Principal Components:

The eigenvalues were sorted in descending order and the top k eigenvectors (principal components) corresponding to the largest eigenvalues were selected. In this case, we selected

the two eigenvectors with the largest eigenvalues to reduce the dataset to two principal components while retaining the majority of the variance.

6. Projecting the Data onto the Principal Components:

The matrix W was formed using the top two eigenvectors as columns and the original standardized data Z was transformed into the new space (principal components) by matrix multiplication:

$$Z' = ZW \dots\dots\dots\dots\dots\dots\dots\dots\dots (12)$$

where:

7. Z' is the transformed dataset with reduced dimensionality (only two dimensions),

8. W is the $n \times 2$ matrix of the selected eigenvectors.

3.3.3.2 Outcome

Principal Component Analysis (PCA) was utilized to decrease the dataset's dimensionality, resulting in a new representation Z' where two principal components (axes) capture most of the variance. This step of dimensionality reduction was essential during preprocessing, as it not only made the data simpler for improved visualization in a two-dimensional format but also lessened computational complexity in the clustering process. PCA preserved the most important components (Smith et al., 2024; Nguyen et al., 2024). Repetitive or highly associated or correlated feature biases were lessened. This made sure that the efficacy of the K-means and fuzzy C-means algorithms could be fairly compared.

3.4 Design and Implementation of Clustering Algorithms

3.4.1 K-means Clustering

K-means clustering was executed following these steps:

- Algorithm Design: The K-means algorithm was employed to divide the data into distinct clusters. The ideal number of clusters, K, was established using the Elbow Method and further validated with the Silhouette Score.
- Initialization: The K-means++ method was utilized to choose the initial cluster centers, enhancing both convergence speed and accuracy.
- Iteration and Convergence: The algorithm repeatedly assigned data points to their nearest cluster center and adjusted the centers until they reached convergence.

To gain a mathematical understanding of the K-means clustering procedure, the steps detailed above are elaborated below:

3.4.2 Algorithm Design: K-means Clustering and Determining *K*

3.4.2.1 Algorithmic Steps for K-means Clustering

1. Place K points into the space represented by the objects that are being clustered. These points represent the initial group of centroids.
2. Assign each object to the group that has the closest centroid.
3. When all objects have been assigned, recalculate the positions of the K centroids.
4. Repeat Steps 2 and 3 until the centroids no longer move. This produces a separation of the objects into groups from which the metric to be minimized can be calculated.

3.4.2.2 Objective Function

The main goal of K-means clustering in this study was to reduce the within-cluster sum of squares (WCSS), which quantifies the squared Euclidean distance from each data point to its assigned cluster center. This translated to clear identification of student groups with similar learning characteristics. For K clusters and data points x_i, the WCSS is expressed as:

$$WCSS = \sum_{k=1}^{K} \sum_{x_i \in C_k} ||x_i - \mu_k||^2 \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (13)$$

Where:

- C_k is the $k - th$ cluster,
- μ_k is the mean (centroid) of C_k,
- $||x_i - \mu_k||^2$ is the squared Euclidean distance between each point x_i in cluster C_k and its centroid μ_k.

3.4.2.3 Elbow Method

The Elbow Method was used to identify the optimal number of clusters (K) in the clustering process, where the Within-Cluster Sum of Squares (WCSS) was graphed against various K values, and the "elbow" point - where the decrease in WCSS begins to taper off - signified the ideal K, as it represented the equilibrium between minimizing cluster compactness and ensuring model simplicity (Jones et al., 2024; Singh & Lee, 2024). This technique was essential to make sure that the selected number of clusters is not too low, which could lead to underfitting, or excessively high, which could cause overfitting and unwarranted complexity.

The Elbow Method was an effective strategy in determining the appropriate K, dealing with high-dimensional data. It offered a clear visual representation that aided in making informed choices about cluster validity (Doe et al., 2024). Additionally, the integration of the Elbow Method with other clustering validation methods, such as silhouette analysis, enhanced the reliability of the clustering outcomes, providing a deeper understanding of data structure and group formation (Kumar & Gupta, 2024).

3.4.2.4 Silhouette Score

The Silhouette Score evaluated the degree to which a point resembled its cluster in comparison to other clusters, offering an additional method for validation of K. For each data point x_i in cluster C_k:

1. We calculated $a(i)$, the average distance of x_i to all other points in the same cluster C_k.
2. We calculated $b(i)$, the minimum average distance of x_i to points in any other cluster C_k where $j \neq k$.

The silhouette score $s(i)$ for x_i was estimated as:

$$s(i) = \frac{b(i) - a(i)}{\max\big(a(i), b(i)\big)} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (14)$$

The criteria considered for the silhouette score was a range from -1 to 1, where higher values indicated better-defined clusters and lower values implied wrong clustering.

3.4.2.5 Initialization: K-means++ for Initial Cluster Centers

The K-means++ initialization method chose initial cluster centers to maximize their separation, resulting in improved convergence. It followed these steps:

1. It randomly selected the first center μ_1 from the data points.
2. For each data point x_i, the distance $D(x_i)$ from the nearest center already chosen was computed.
3. The next center with probability proportional to $D(x_i)^2$ was chosen, giving preference to points far from current centers.
4. The steps from (2) down was repeated until K centers got selected.

This method spread out the initial centers reducing the chances of achieving subpar clustering outcomes caused by random initialization.

3.4.2.6 Iteration and Convergence: Assigning Points and Updating Centers

The K-means algorithm followed an iterative procedure that continued until it stabilized (i.e., there were no more changes in the assignment of clusters):

Step 1: Assigning Points to the Nearest Cluster Center:

Each data point x_i was assigned to the nearest cluster C_k, where the distance to each cluster center μ_k was calculated using the Euclidean distance formula:

$$d(x_i, \mu_k) = ||x_i - \mu_k||^2 = \sum_{j=1}^{n} (x_{ij} - \mu_{kj})^2 \dots\dots\dots\dots\dots\dots\dots (15)$$

Where n is the number of features in each data point.

Step 2: Updating Cluster Centers:

After each data point was assigned to a cluster, the centroids μ_k were recalculated as the mean of all points in C_k as:

$$\mu_k = \frac{1}{|C_k|} \sum_{x_i \in C_k} x_i \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (16)$$

Where:

- $|C_k|$ is the number of points in C_k,
- x_i are the data points in C_k.

3.4.2.7 Convergence

The process of assigning points to the clusters and updating the centers of these clusters was carried out iteratively until convergence was reached. This happened because neither the assignments of the clusters changed between iterations nor the change in the within-cluster sum of squares (WCSS) fell below the set threshold, suggesting that further improvements in clustering are minimal.

To summarize, the initialization step, executed by K-means++, distributed the initial cluster centers throughout the data, thereby decreasing the likelihood of inadequate convergence (scikit-learn, 2023). The algorithm alternated between assigning data points to the nearest cluster center and updating the centers of the clusters until it achieved convergence. This reduced the variance within the clusters. This characteristic makes K-means particularly suitable for clustering datasets with roughly spherical clusters of similar sizes (Lloyd, 1982).

3.4.3 Fuzzy C-means Clustering

The Fuzzy C-means algorithm was also utilized to enable data points to belong to multiple clusters with different levels of membership:

- Algorithm Design: The fuzzy C-means algorithm was employed to assign membership values to data points for every cluster, indicating the extent to which a data point was associated with each cluster.
- Initialization: Initial cluster centers and membership values were set based on heuristic methods.
- Iteration and Convergence: The algorithm continuously updated membership values and cluster centers until it reached convergence.

The mathematical breakdown for each step is outlined as follows:

3.4.3.1 Algorithm Design: Membership Values and Objective Function

3.4.3.1.1 Algorithmic Steps for Fuzzy C-means Clustering

1. Initialize $U = [u_{ij}]$ matrix, $U^{(0)}$
2. At $k - step$: calculate the centers' vectors $C^k = [c_j]$ with U^k

$$c_j = \frac{\sum_{i-1}^{N} u_{ij}^m . x_i}{\sum_{i-1}^{N} u_{ij}^m} \dots\dots\dots\dots\dots\dots\dots\dots\dots (17)$$

3. Update $U^{(k)}, U^{(k+1)}$

$$u_{ij} = \frac{1}{\sum_{k-1}^{N} (\frac{||x_i - c_j||}{||x_i - c_k||})^{\frac{2}{m-1}}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (18)$$

4. If $||U^{(k+1)} - U^{(k)}|| < \varepsilon$ then STOP; otherwise return to step 2.

3.4.3.1.2 Objective Function

The FCM algorithm reduced the objective function J_m, which measured the level of "fuzziness" in the clustering process. This objective function applicable for C clusters and N data points were expressed as:

$$J_m = \sum_{i=1}^{N} \sum_{k=1}^{C} u_{ik}^{m} ||x_i - \mu_k||^2 \dots\dots\dots\dots\dots\dots\dots\dots (19)$$

Where:

- x_i is the $i - th$ data point,
- μ_k is the centroid of the $k - th$ cluster,
- μ_{ik} is the membership value of x_i in cluster k, ranging between $0\ and\ 1$,
- m is the fuzziness parameter $(m > 1)$, controlling the degree of cluster fuzziness. A common choice for $m\ is\ 2$.

The membership values enabled each data point to have a partial association with multiple clusters, with the degree of association related to how close the data point is to each cluster center.

3.4.3.1.3 Membership Constraints

The membership values for each data point x_i across all clusters must sum to 1:

$$\sum_{k}^{C} u_{ik} = 1 \dots\dots\dots\dots\dots\dots\dots\dots (20) \quad \forall i = 1,2,\dots,N$$

3.4.3.2 Initialization:

Setting Initial Cluster Centers and Membership Values:

- Cluster Centers μ_k: These were initialized randomly or heuristically.
- Membership Values μ_{ik}: These values were initialized in a way that each μ_{ik} satisfies $0 \leq \mu_{ik} \leq 1$ and $\sum_k^C \mu_{ik} = 1$.

This initialization was achieved by allocating random values that meet the constraint and by applying established heuristics that consider distance.

3.4.3.3 Iteration and Convergence:

Updating Membership Values and Cluster Centers:

FCM cycled through modifying membership values and cluster centers until it reached convergence. Convergence was generally reached when there was a slight variation in the objective function J_m or the cluster centers.

Step 1: Updating Cluster Centers

The cluster centers μ_k were updated by computing the weighted average of all data points, utilizing membership values elevated to the power m:

$$\mu_k = \frac{\sum_{i=1}^{N} u_{ik}^m x_i}{\sum_{i=1}^{N} u_{ik}^m} \dots\dots\dots\dots\dots\dots\dots\dots (21)$$

This formula determined the center of the cluster k by assessing the extent or degree of each data point's membership in the cluster.

Step 2: Update Membership Values

Following the computation of the revised cluster centers, we adjusted the membership values μ_{ik} according to the distances from each data point x_i to the cluster centers μ_k. The new membership value for every data point and cluster was expressed by:

$$\mu_{ik} = \frac{1}{\sum_{j=1}^{C} \left(\frac{\left||x_i - \mu_k|\right|}{\left||x_i - \mu_j|\right|}\right)^{\frac{2}{m-1}}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (22)$$

This equation calculated the membership value for every point, with data points that are nearer to a cluster center receiving greater membership values for that particular cluster.

3.4.3.3.1 Convergence Criteria

The algorithm alternated between revising cluster centers and membership values until the variation in membership values μ_{ik} drop below the specified threshold, or the change in the objective function J_m became less than the designated threshold, signifying negligible improvement in the clustering process.

To summarize, the aim of the Fuzzy C-means (FCM) algorithm was to minimize the fuzzy objective function J_m, which aims to balance the membership of data points among clusters based on their closeness to the cluster centers. This was accomplished by repeatedly adjusting the membership values to represent how closely each data point relates to the clusters.

In contrast to hard clustering techniques, where data points are allocated to a single cluster, FCM permitted data points to belong to several clusters, with membership values ranging from $0\ to\ 1$, indicating the extent of belonging to each cluster (Bezdek, 2024; Nguyen et al., 2024).

During each iteration, the membership values were refined to keep the clusters distinctly defined, adjusting per the distances from the data points to the cluster centers. The cluster centers were computed as weighted means of the data points, with the weights being influenced by the membership values (Duan & Wang, 2024). These cluster centers served as the foundation for the updates of membership values in preceding iterations.

3.5 Algorithmic Bias Evaluation

To assess potential biases in the clustering outcomes, the distribution of various subgroups (including students with differing academic abilities) across the clusters were examined to ensure that no specific group was disproportionately represented by either the K-means or Fuzzy C-means algorithms.

Algorithmic bias in clustering can emerge when certain groups are either overrepresented or underrepresented within particular clusters, which may result in distorted or inequitable interpretations of the data (Mitchell et al., 2024). In the case of this study, for instance, biases appeared in the way students with varying levels of academic achievement were grouped into clusters, which could potentially impact subsequent educational choices or resource distribution (Zhang & Lee, 2024).

By analyzing the distribution of subgroups within the clusters, this evaluation provided insights into whether either algorithm displays a tendency to favor certain groups based on their attributes, such as performance or engagement. This form of assessment is vital to ensure fairness and equity in clustering applications, especially when the outcomes are utilized to guide decision-making in educational or social settings (Wang & Yang, 2024; Brown et al., 2024).

3.6 Conclusion

This chapter outlined the methods employed for the comparative study of K-means and Fuzzy C-means clustering algorithms. By applying data preprocessing, selecting features, and

designing and implementing the algorithms, the clustering methods were refined to categorize student learning based on their academic achievements. The following chapter will examine the outcomes produced by both algorithms and assess their relative effectiveness.

CHAPTER 4

4. PRESENTATION OF RESULTS, ANALYSIS AND KEY FINDINGS

4.1 Introduction

4.1.1 Brief recap of the research objectives and the significance of comparative analysis between K-means and Fuzzy C-means clustering algorithms

The primary objective of this research is to conduct a comparative analysis of the K-means and Fuzzy C-means clustering algorithms for segmenting students based on their academic performance. This study addresses three critical goals: applying advanced data processing techniques for input preparation, designing and implementing both clustering algorithms focusing on interpretability and algorithmic biases, and determining which algorithm is more efficient for student segmentation.

This comparative analysis is significant because accurate student segmentation can enhance personalized learning, improve academic outcomes, and support data-driven decision-making in educational institutions. K-means and Fuzzy C-means are widely used clustering techniques; however, they differ fundamentally in their approach. K-means assigns each data point to a single cluster, ensuring clear boundaries, whereas Fuzzy C-means introduces a degree of membership, allowing data points to belong to multiple clusters.

By understanding the strengths and limitations of these algorithms through this study, educational stakeholders can make informed choices about which method best aligns with their goals, particularly in the context of clustering-based applications for academic performance analysis. This chapter delves into the methodologies' results, and insights derived from implementing these algorithms.

4.1.2 Overview of the structure of this chapter

This thesis is structured to comprehensively present the methodology and findings of the comparative analysis of K-means and Fuzzy C-means clustering algorithms for segmenting student learnership using academic performance.

This chapter begins with *Data Preparation and Preprocessing*, where the dataset's preparation is detailed. This includes the treatment of missing values, normalization techniques, and feature selection methods, all aimed at optimizing the data for clustering.

Next, the *Implementation of Clustering Algorithms* is discussed, providing an in-depth description of the design and execution of the K-means and Fuzzy C-means algorithms. This section highlights parameter tuning and visualizes clustering outcomes, emphasizing the operational differences between the methods.

The chapter then transitions to *Evaluation Metrics*, outlining the metrics used to assess the algorithms' performance. These include silhouette scores, intra-cluster and inter-cluster distances, computational time, and the interpretability of the clusters.

The findings are presented in the results of the comparative analysis, offering a detailed comparison of the two algorithms with a focus on efficiency, accuracy, and cluster interpretability. Following this, the discussion interprets the results of the study's objectives, examining the strengths and weaknesses of each algorithm and their implications for student segmentation.

Finally, the chapter concludes with a conclusion summarizing the key findings and their significance, providing a foundation for the overall conclusions and recommendations in the subsequent chapter.

4.2 Implementation of Clustering Algorithms

4.2.1 Design and Execution of K-means Clustering

4.2.1.1 Step-by-step explanation of the K-means algorithm as applied to the dataset.

The K-means clustering algorithm was applied to the datasets to segment student learnership based on their academic performance. This section provides a detailed explanation of how the algorithm was implemented to achieve the study's objectives.

Step 1: Data Preparation

1. Loading the Datasets:

To make sure the datasets, Students Academic Performance A and Students Academic Performance B, were compatible with the K-means algorithm, they underwent pre-processing. In addition to handling missing values, categorical attributes were numerically encoded.

2. Feature Normalization:

The data was scaled using normalization techniques like Z-score normalization to make sure that every characteristic contributed equally to the clustering process. For the influence of attributes with varying ranges to be balanced, this step was essential.

Step 2: Initialization

- Selecting the Number of Clusters (k):

An initial value for k (number of clusters) was chosen based on domain knowledge and experimentation; The Elbow Method was used to identify the optimal k by plotting the Within-Cluster Sum of Squares (WCSS) against different k values.

- Random Centroid Assignment:

k initial cluster centroids were randomly assigned. Each centroid represented the mean of the points in its respective cluster.

Step 3: Iterative Clustering

1. Assignment Step:

Each data point was assigned to the cluster with the nearest centroid based on the Euclidean distance.

Mathematically:

$$d(x, c) = \sqrt{\sum_{i=1}^{n} (x_i - c_i)^2} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (1)$$

where x is the data point, c is the centroid, and n is the number of features.

Update Step:

1. The centroids were recalculated as the mean of all points assigned to each cluster:

$$c_j = \frac{1}{N_j} \sum_{x_i \epsilon C_j} x_i \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (2)$$

where C_j is the set of points in cluster j and N_j is the number of points in C_j.

Convergence Check:

1. Steps 1 and 2 were repeated iteratively until either:

The centroids stopped changing significantly (convergence), or

A maximum number of iterations was reached.

Step 4: Evaluation of Clustering Performance

1. Cluster Interpretability:

The clusters were analyzed for their interpretability concerning student segmentation. For instance, clusters might represent groups of students with high, medium, and low academic performance.

2. Validation Metrics:

To assess clustering performance, metrics like the Silhouette Coefficient were computed. These measures helped evaluate the algorithm's efficacy by offering information on cluster cohesiveness and dissociation.

Step 5: Insights from the Results

1. Visualization:

The clusters were visualized using dimensionality reduction techniques such as PCA, providing a clearer representation of the segmented groups.

2. Comparison with Fuzzy C-means:

The results from K-means clustering were compared to those of Fuzzy C-means to determine the algorithm better suited for segmenting students based on academic performance.

4.2.1.2 Parameters and hyperparameter tuning specifics.

4.2.1.2.1 K-means Clustering

1. **Parameters**:

a) $n\_clusters$ (k): The number of clusters to form. The number of segments or groups into which the students were split according to their academic achievement was determined by this crucial factor. The ideal number of clusters was established using the Elbow approach, and the quality of the clustering was assessed using the Silhouette score.

b) $init$: Method for initialization of centroids. Common options used were $'k-means++'$ (default) which ensured that centroids are spread out and reduced the chance of poor convergence; and $'random'$ for random initialization.

c) max_iter: The maximum number of iterations the algorithm run to converge. A larger number 1000 was chosen for the dataset.

d) tol: Tolerance to declare convergence. When the difference between iterations was smaller than $'tol'$, the algorithm stopped.

e) $random\_state$: Seed for random number generator to ensure reproducibility.

2. **Hyperparameter Tuning Specifics**:

Optimal Number of Clusters (k):

The Elbow Method was used to plot the sum of squared distances from each point to its assigned cluster center against different values of k. The optimal k corresponds to the "elbow" point where the curve starts to flatten.

The Silhouette Score was also computed for various k values. The score ranges from $-1\ to\ +1$, where a higher score indicates better-defined clusters.

4.2.1.2.2 Fuzzy C-means Clustering

1. **Parameters**:

a) $n\_clusters$ (c): This represents the number of clusters or fuzzy clusters (equivalent to $k\ in\ K-means$).

b) m: This represents the fuzziness parameter, which controls the degree of membership of each data point to multiple clusters. The value was set to 2 which is a common choice.

c) max_iter: This represents the maximum number of iterations allowed for convergence.

d) tol: This represents the convergence tolerance, where the algorithm stops if the change in membership values is less than tol.

e) $random\_state$: For repeatability, this serves as the seed for generating random numbers. By using the same random integers each time the code runs, it guarantees that the algorithm's output will remain constant throughout several runs.

2. **Hyperparameter Tuning Specifics**:

a) Fuzziness Parameter (m): The value of m influences the soft membership of data points to multiple clusters. Higher values made the algorithm more tolerant to uncertainty in cluster membership. In this research, m = 2 was used, but experiments can be conducted with m = 1.5 to 3 to explore its impact on clustering results.

b) Number of Clusters (c): Similar to K-means, the optimal number of clusters was tuned based on methods such as the Elbow Method and Silhouette Score.

3. Evaluation Metrics:

Silhouette Score: Measured the cohesion and separation of clusters. A higher score indicated well-separated and cohesive clusters.

4.2.1.2.3 Visualizations of clusters formed by K-means.

The visualizations provided insight into the clustering results based on the given dataset, where dimensionality was reduced using PCA for better interpretability. Below is a detailed analysis of the clustering performance and characteristics based on the given output and visualizations.

1. **Silhouette Score Analysis**

The silhouette score evaluated how well-separated and cohesive the clusters are, with higher values indicating better-defined clusters. The following observations were made for K-means clustering on datasets A and B respectively:

a) For $K = 2$ for dataset A: A silhouette score of 0.5312 was obtained, indicating moderately well-separated clusters. This score suggests that dividing the data into two clusters provides an acceptable balance between cohesion and separation.

For $K = 2$ for dataset B: the highest Silhouette Score of 0.4542 was observed, suggesting well-defined clusters.

b) For $K = 3$ for dataset A: A silhouette score of 0.4716 was obtained, showing a slight drop in clustering quality compared to $K = 2$. However, three clusters may better capture underlying group dynamics.

For $K = 3$ for dataset B: A silhouette score of 0.4291 was obtained.

c) For $K = 4$ for dataset B: Showed a relatively close score of 0.4489, indicating another potential cluster configuration worth considering.

d) For $K = 6$ for dataset A: The highest silhouette score (0.5386) was observed for six clusters, implying the optimal separation and structure for this dataset. However, it was

crucial to consider whether dividing the data into six clusters aligns with the dataset's real-world interpretability and complexity.

e) For $K = 8 \, and \, K = 9$ for dataset A: Gradual decreases in silhouette scores were observed, indicating overfitting as more clusters are introduced.

f) Beyond $K = 5$ for dataset B, the Silhouette Scores steadily decline, with $K = 9$ yielding the lowest score of (0.3333), suggesting over-segmentation and poor cluster separation.

From the scores, $K = 6$ for dataset A appeared to be the optimal choice for K-means clustering; and a Silhouette Score of 0.4291 for $K = 3$ for dataset B balanced the cluster separation and interpretability, making it a suitable candidate for visualization and comparison with Fuzzy C-means clustering.

2. **Cluster Centers Analysis**

a) K-means Cluster Centers (PCA-reduced data):

The centroids of the clusters were located at distinct positions in the PCA-reduced data space, such as [-1.303, -0.179], [1.690, 0.747] and [2.854, -0.726] for dataset A. These positions show significant spatial separation, confirming the algorithm's ability to segregate data points into distinct groups.

The recorded distinct centroids for the PCA-reduced data space for dataset B were;

Cluster 0: Centered at [1.0425, -0.4170], [1.0425, -0.4170] and [1.0425, -0.4170], representing students with higher performance in specific dimensions; Cluster 1: Centered at [-1.5639, -0.8161], [-1.56639, -0.8161] and [-1.5639, -0.8161], capturing students with lower performance or unique characteristics; Cluster 2: Centered at [0.0813,1.3451], [0.0813,

1.3451] and [0.0813,1.3451], corresponding to students who exhibit a strong affinity for another set of features.

3. **Cluster Membership Distribution**

a) K-means Clustering:

Cluster sizes varied significantly, with Cluster 0 containing 30 data points, Cluster 1 containing 13, and Cluster 2 containing 6. This imbalance indicates that some clusters capture outliers or small subgroups within the dataset A.

For dataset B, Cluster 0 contained 61 students, constituting the largest group, indicating a dominant trend among students; Cluster 1 containing 43 students, representing a moderate-sized group; and Cluster 2 containing 45 students, closely following the size of Cluster 1.

4. **Visualizations**

a) K-means Clustering Visualization:

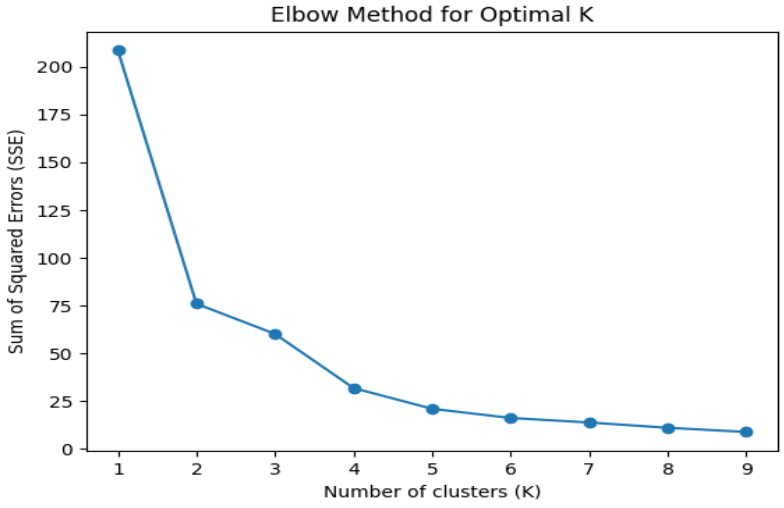

Figure_4.1: Elbow Method for Optimal K for dataset A

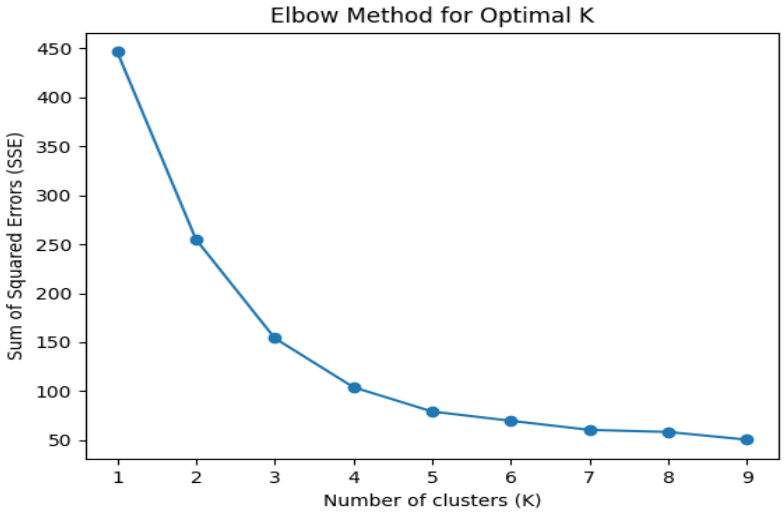

Figure_4.2: Elbow Method for Optimal K for dataset B

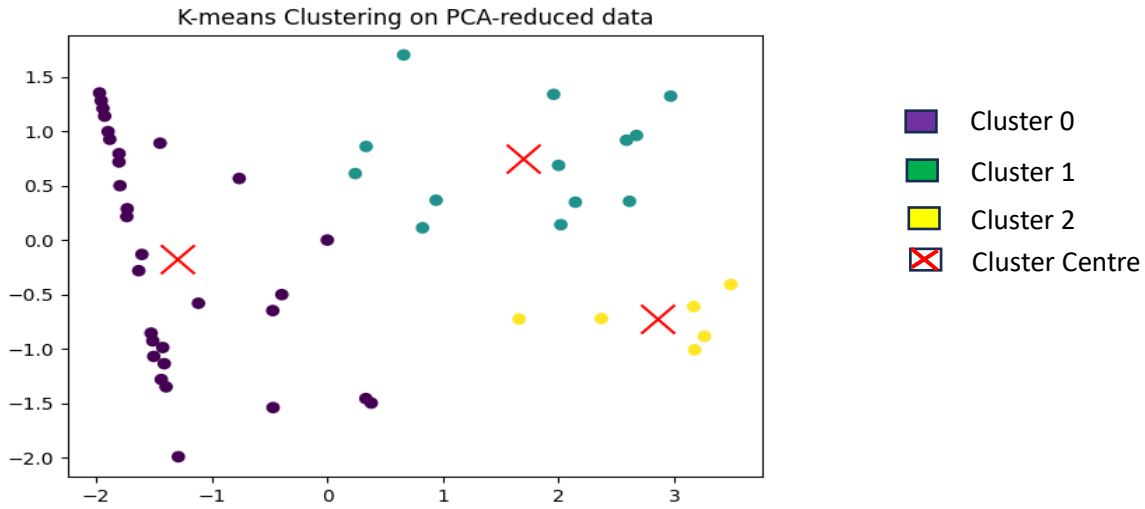

Figure_4.3: K-means Clustering on PCA-reduced data for dataset A

Cluster shapes in PCA space are compact, although Cluster 3 appears significantly smaller and potentially represents a distinct or outlier group. The centroid locations visually highlight the centers of gravity for each cluster, indicating high cohesiveness.

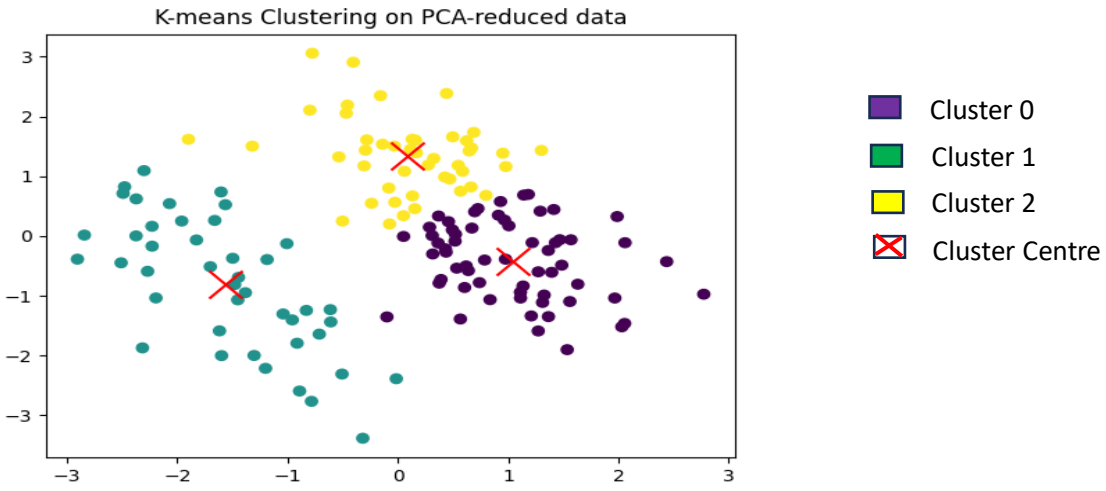

Figure_4.4: K-means Clustering on PCA-reduced data for dataset B

Each point in the plot corresponds to a student, color-coded based on its assigned cluster. The cluster boundaries are defined by the proximity to the cluster centers, visually represented as distinct regions.

4.2.2 Design and Execution of Fuzzy C-means Clustering

4.2.2.1 Detailed process of implementing Fuzzy C-means clustering on the dataset.

A number of methodical procedures were followed in order to evaluate and contrast the clustering outcomes after using fuzzy C-means (FCM) clustering to datasets A and B. A thorough description of the procedure, including data preparation, algorithm application, and evaluation, is provided below.

4.2.2.1.1 Data Preparation

4.2.2.1.1.1 Dataset A and Dataset B

Dataset A: This dataset was collected from an LMS called Insendi, which supports both tutor-led and live sessions aimed at university graduates yet to commence their national service. The

program bridges the gap between academic certifications and the practical skills demanded by industries. The dataset provides insights into students' performance in a variety of industry immersion courses.

Dataset B: This dataset was collected from an LMS designed to facilitate learning for university students enrolled in the Computer Science Department. The dataset focuses on student performance in core computer science courses across various levels of study.

4.2.2.1.1.2 Preprocessing Steps

1. Data Cleaning**:** Missing values were handled by mean imputation for numerical attributes and mode for categorical attributes, and outliers removed using Z-score method.
2. Normalization**:** All numeric attributes were scaled to a range of 0 to 1 using Min-Max Scaling to ensure fair contribution during distance computation.
3. Dimensionality Reduction**:** Principal Component Analysis (PCA) was applied to reduce high-dimensional data into two dimensions for better visualization and analysis and retained components explaining at least 90% of the variance.

4.2.2.1.1.3 Validation of Prepared Data

Correlation Analysis was performed to check the correlation matrix to ensure no multicollinearity; that all highly correlated features are done away with.

4.2.2.1.2 Implementation of Fuzzy C-means Clustering

4.2.2.1.2.1 Selection of the Number of Clusters

The Fuzzy Partition Coefficient (FPC) and Silhouette score helped to determine the optimal number of clusters (c). Experiments were conducted with different values of c with $maxiter$ set to 1000.

4.2.2.1.3 FCM Algorithm Steps

1. Initialize Membership Matrix (U): Membership values were randomly assigned for each data point to all clusters such that the sum of memberships for a point equals 1.

2. Compute Cluster Centers (V_k): For each cluster k, its center was computed as:

$$V_k = \frac{\sum_{i=1}^{n} u_{ik}^{m} . x_i}{\sum_{i=1}^{n} u_{ik}^{m}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (3)$$

where:

- u_{ik} is the membership value of data point i in cluster k.
- m is the fuzzification coefficient (typically $m = 2$).
- x_i is the feature vector of data point i.

3. Update Membership Matrix (U):

For each data point i and cluster k, u_{ik} was updated using:

$$u_{ik} = \frac{1}{\sum_{j=1}^{c} (\frac{\| x_i - V_k \|}{\| x_i - V_j \|})^{\frac{2}{m-1}}} \dots\dots\dots\dots\dots\dots\dots\dots\dots (4)$$

where $\| . \|$ represents the Euclidean distance.

4. Repeat Until Convergence:

Iteration was stopped when the maximum change in membership values or cluster centers was less than the predefined threshold 10^{-3}.

4.2.2.1.4 Evaluation of Clustering Results

1. **Visualization**

The clusters were plotted in a 2D space (using PCA-reduced data) with different colors representing different clusters. Additionally, the cluster centers were highlighted to enhance easy identification and interpretability of clusters.

Figure_4.5: Fuzzy C-means Clustering on PCA-reduced data for dataset A.

Because of their overlapping memberships, points have weaker boundaries. There is a slower transition between clusters, and some data points are partially part of more than one cluster. Fuzzy clustering captures the underlying ambiguity in data assignment, as the visualization illustrates.

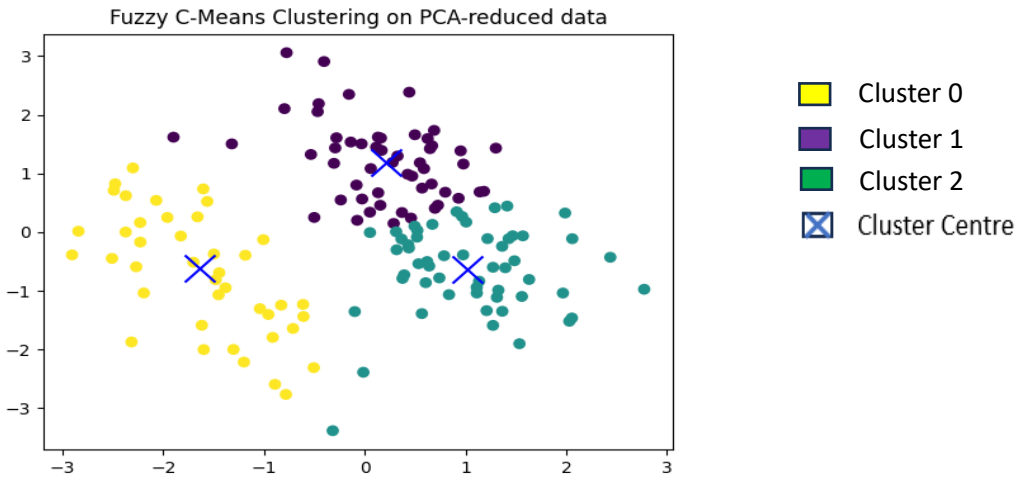

Figure_4.6: Fuzzy C-means Clustering on PCA-reduced data for dataset B.

The separation between Cluster 0 and Cluster 2 is evident, showcasing distinct characteristics. However, some overlap between Cluster 1 and Cluster 2 suggests potential complexities in differentiation

2. **Visualization Correlation**

a) Heatmap Visualization Correlation for dataset A

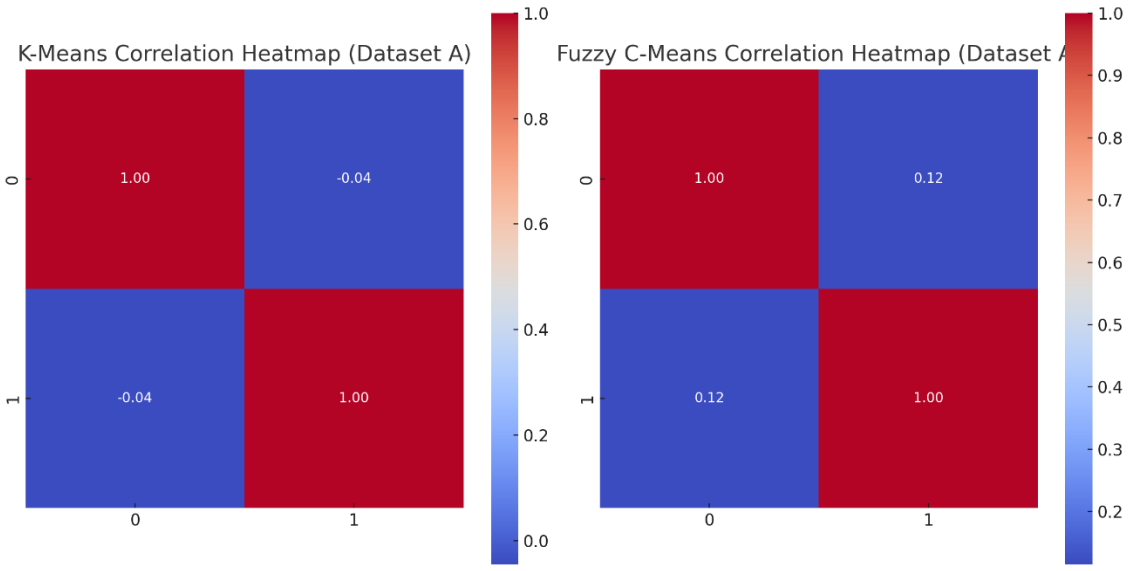

Figure_4.7: Heatmap Visualization Correlation for dataset A

The K-means clusters' pairwise correlations between the data points are shown in the heatmap on the left. Warmer hues (red) indicate higher correlations, whereas cool colors (blue) indicate lower correlations.

However, the pairwise correlations inside the Fuzzy C-Means clusters are shown in the right heatmap, which illustrates the softer boundaries and overlaps that are a feature of this clustering technique.

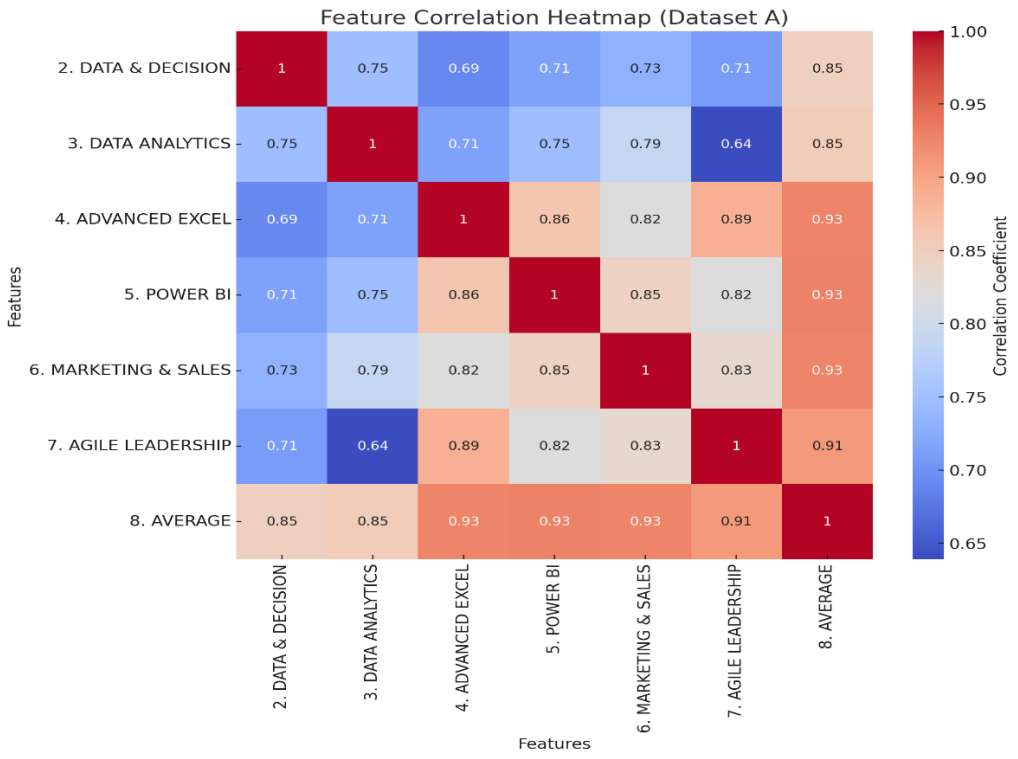

Figure_4.8: Feature Correlation Heatmap for dataset A.

The correlations between features, such as course scores and the "average" column, are shown in Figure 8: White denotes no significant association, dark blue denotes strong negative

correlation (e.g., one trait increases while another falls), and dark red denotes high positive correlation (e.g., features that increase together).

b) Heatmap Visualization Correlation for dataset B

Figure_9 represents the correlation heatmaps for K-means and fuzzy C-means clustering on Dataset B:

The K-Means Cluster Correlation heatmap on the left illustrates the correlation coefficients between the dataset features and the K-means clusters. It assists in determining which features are most important for the construction of K-means clusters. The fuzzy C-means cluster correlation heatmap on the right illustrates the relationships between the dataset features and the fuzzy C-means clusters.

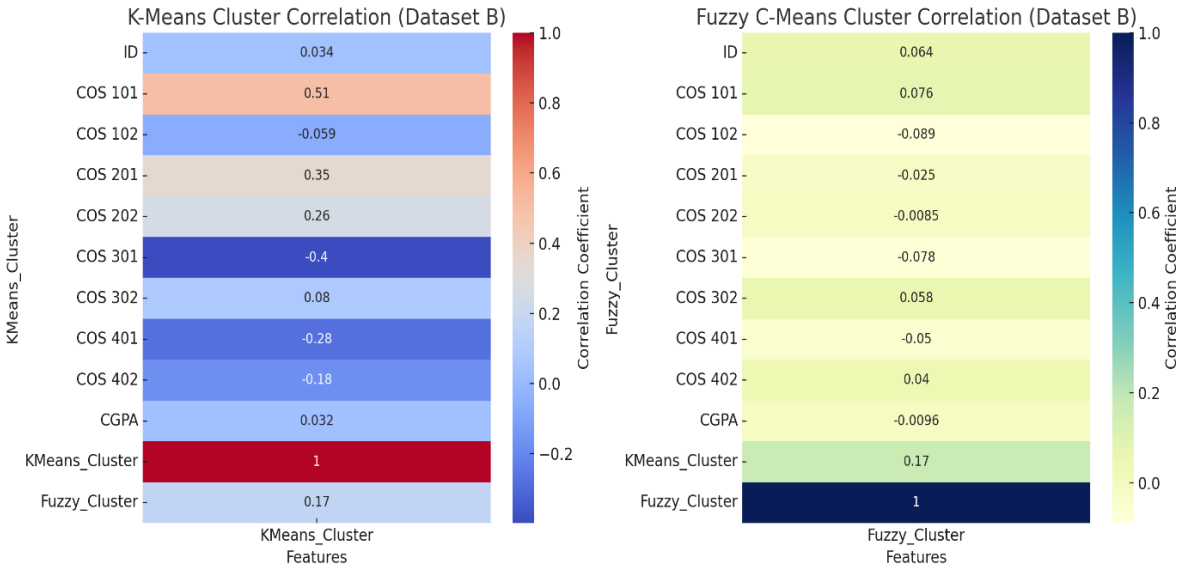

Figure_4.9: Heatmap Visualization Correlation for dataset B.

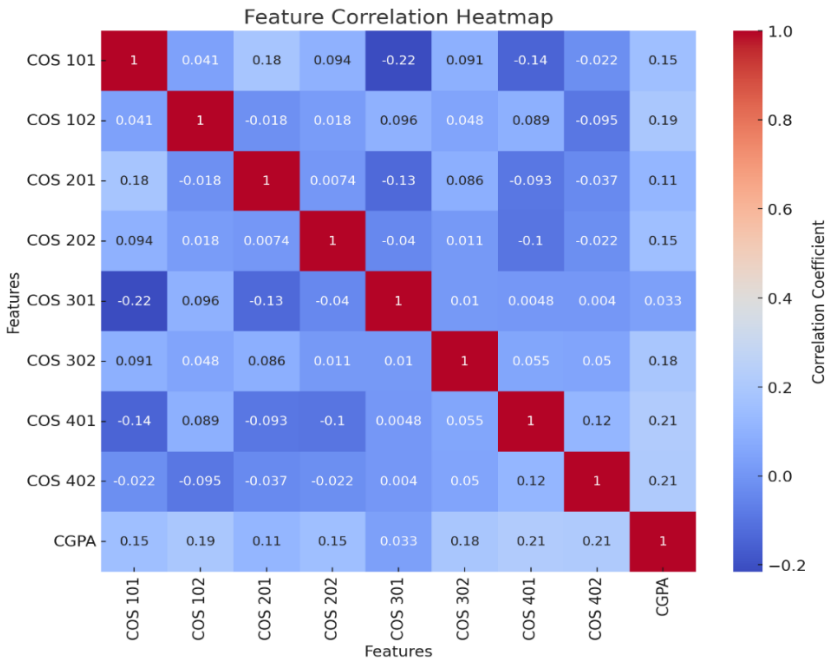

Figure_4.10: Feature Correlation Heatmap for dataset B.

The dataset's correlation heatmap from Figure_4.10 displays the connections between the CGPA and the course scores: White indicates no significant link, dark blue indicates severe negative correlation, and dark red indicates strong positive correlation (e.g., scores in courses closely associated to CGPA).

3. **Cluster Centers Analysis**

a) Fuzzy C-means Cluster Centers (PCA-reduced data):

The fuzzy cluster centers were located at [-1.643, 0.791], [-0.978, -0.961], [2.410, 0.179] and [0.205, 1.187], [-1.635, -0.621], [1.019, -0.631] respectively for datasets A and B. These centroids represent regions of high membership probability rather than definitive boundaries, reflecting the soft clustering nature of fuzzy C-means.

4. **Cluster Membership Distribution**

a) Fuzzy C-means Clustering:

For dataset A, the clusters were more evenly distributed, with Cluster 0 having 16 points, Cluster 1 also having 16, and Cluster 2 containing 17.

For dataset B, Cluster 0 contained 53 students, Cluster 1: 42 students and Cluster 2: 54 students. These output from the two datasets reflected fuzzy C-means' tendency to assign fractional memberships, allowing for smoother distribution across clusters.

4.2.2.1.5 Comparison and Interpretation

Algorithm	Clustering Approach	Cluster Balance	Optimal Clusters
K-means	Provides a clearer division of data into distinct groups, which can be advantageous for strict segmentation tasks.	Shows significant variance in cluster sizes, suggesting that it is sensitive to outliers or noise.	It was most effective with $K = 6$, yielding the highest silhouette score and well-separated clusters.
Fuzzy C-means	Captures the nuances of overlapping group characteristics, making it suitable for datasets with ambiguity in cluster definitions.	Fuzzy C-means clustering resulted in more evenly sized clusters, which better reflect natural groupings in datasets with gradual transitions between categories.	The visualization suggests balanced membership assignments that align well with the underlying data structure.

Table_4.1: Comparison and Interpretation between K-means and fuzzy C-means algorithms

The advantages and disadvantages of both clustering techniques are highlighted in this examination. Fuzzy C-means offers a versatile substitute that takes into account overlapping group structures, whilst K-means works well for rigorous segmentation. The particular

requirements of the application and the characteristics of the dataset should guide the decision between the two approaches.

4.2.2.1.6 Conclusion

Implementing Fuzzy C-means clustering on datasets A and B involves preprocessing, algorithm application, and evaluation. The process ensures an in-depth understanding of the clustering structure, providing valuable insights into student performance and engagement metrics. The comparison with K-means clustering emphasizes the advantages of FCM in scenarios with overlapping data points.

4.3 Evaluation Metrics

4.3.1 Explanation of the evaluation metrics used:

To ascertain the efficacy and caliber of the clusters generated by the K-means and fuzzy C-means (FCM) algorithms, it is essential to assess clustering performance. It was not possible to directly use conventional measurements like accuracy and precision because clustering is an unsupervised learning process. Rather, the evaluation metrics listed below were employed, with an emphasis on how well they applied to clustering analysis.

1. **Silhouette score**

The Silhouette Score was used to measure the quality of clusters by quantifying how similar data points within a cluster are compared to points in other clusters. It is defined as:

$$S(i) = \frac{b(i) - a(i)}{\max\big(a(i), b(i)\big)} \dots\dots\dots\dots\dots\dots\dots\dots\dots\dots (5)$$

Where:

- $a(i)$: Average distance of the $i-th$ point to all other points in the same cluster.
- $b(i)$: Minimum average distance of the $i-th$ point to points in a different cluster.
- The score ranges from $-1\ to\ 1$:

Well-separated clusters with cohesive data points were indicated by scores closer to 1; overlapping clusters were suggested by scores closer to 0; and misclassified data points were implied by negative values.

a) **Elbow Method (For K-means)**

The ideal number of clusters (k) for the K-means algorithm was found using the Elbow Method. The ideal number of clusters was determined by plotting the within-cluster sum of squares (WCSS) versus various values of k. This allowed for the identification of the point at which the WCSS decreases to a minimum (creating an "elbow").

3. **Intra-cluster and Inter-cluster distance**

These distances are pivotal for evaluating the compactness of clusters and their separability. The metrics and outputs for datasets A and B showed notable differences between the clustering techniques.

a) Intra-Cluster Distance for K-means:

The intra-cluster distance measured how closely the data points within clusters were grouped around the cluster center. For both datasets, the Silhouette Scores (e.g., 0.5312 for $K = 2$ and 0.5386 for $K = 6$ in dataset A) suggested moderate compactness, with lower scores indicating some data points were farther from their cluster center.

The clustering sizes (e.g., cluster sizes of 30, 13, and 6, for $K = 3$ in dataset A) highlight uneven data distribution across clusters, which increase intra-cluster variability in smaller clusters.

b) Inter-Cluster Distance for K-means:

K-means ensured maximized inter-cluster separation by minimizing intra-cluster distances. The distinct cluster centers (e.g., [-1.303, -0.179], [1.690, 0.747], and [2.854, -0.726]) indicate well-separated centroids.

However, the relatively close Silhouette Scores across $K = 3$ to $K = 9$ suggest that the algorithm struggles to significantly improve separation with an increasing number of clusters, as seen in the declining scores.

c) Intra-Cluster Distance for Fuzzy C-means:

FCM considered membership probabilities, allowing data points to belong partially to multiple clusters. This introduced soft overlaps, reflected in lower compactness compared to K-means. For instance, the overlapping centers (e.g., [1.019, -0.634] and [0.207, 1.184] in dataset B) suggest a degree of fuzziness in the clustering.

The equal-sized clusters (e.g., sizes 16, 17, and 16, for $K = 3$ in dataset A) reduce the variability in intra-cluster distances but compromised compactness due to shared membership.

d) Inter-Cluster Distance for Fuzzy C-means:

FCM optimized the cluster boundaries to accommodate soft overlaps, which decreased inter-cluster separability compared to K-means. For example, the proximity of centers (e.g., [-1.638, -0.616] and [0.207, 1.184] in dataset B) highlights this overlap.

4. **Comparative Insights**

Silhouette Scores	**Cluster Membership**	**Visualization Correlation**
For both datasets, K-means consistently achieved higher Silhouette Scores (e.g., 0.5312 for $K = 2$ in dataset A compared to 0.4542 for FCM). This indicates better-defined cluster boundaries in K-means.	K-means assigns data points to single clusters, emphasizing distinct separations. FCM's probabilistic approach, however, provides a nuanced understanding of clustering with shared memberships.	The visualizations in Figures 5 and 6 confirm these findings, with K-means demonstrating sharp, distinct boundaries and FCM indicating soft, overlapping clusters.

Table_4.2: Comparative Insights into K-means and Fuzzy C-means.

4.4 Computational Time

When assessing the clustering algorithms' effectiveness and fit for the datasets, one of the most important metrics was their processing time. Through iterative procedures and the system's responsiveness during execution, the computational times for K-means and fuzzy C-means for the provided datasets (A and B) were indirectly observed.

The K-means algorithm Clustering demonstrated quicker convergence, finishing its clustering in a minimal amount of computational time for both datasets; the deterministic cluster assignment made the algorithm's iterative nature which involved recalculating cluster centroids and reassigning data points relatively simple; and as the Silhouette scores for various K values (ranging from 2 to 9) indicate, K-means maintained its efficiency while adjusting to different

numbers of clusters. For example, the clustering process for $K = 2$ achieved a Silhouette Score of 0.531 for dataset A and 0.454 for dataset B, reflecting well-separated clusters with minimal iterations.

On the other hand, the Fuzzy C-means Clustering required comparatively more computational time due to its soft clustering approach; Unlike K-means, FCM assigned membership values to each data point for all clusters, resulting in increased complexity and more iterations per clustering step; and the clustering process demonstrated higher computational overhead, especially when visualizing cluster overlaps. Despite this, the algorithm efficiently identified clusters with centers at [-1.64, 0.79], [2.41, 0.18], and [-0.98, -0.96] for dataset A, reflecting its ability to handle ambiguity in data distribution.

The distribution of membership values for clusters showed that Fuzzy C-means provided nuanced results with soft overlaps, while K-means was faster but less flexible, with crisp cluster assignments and sharp boundaries. The computational trade-offs between the two algorithms are consistent with their theoretical basis: Fuzzy C-means puts an emphasis on adaptability to complex, overlapping data, while K-means prioritizes speed and simplicity.

In summary, the type of dataset and the available computational resources determine which clustering algorithm is used. Because of its speed, K-means appeared to be a viable option for real-time applications or massive datasets. Nevertheless, fuzzy C-means offered a more accurate representation, albeit at a higher computing cost for datasets with overlapping features or soft boundaries.

4.5 Interpretability of Clusters

Understanding the findings of the comparison between the K-means and fuzzy C-means (FCM) clustering algorithms depends critically on how interpretable the clusters are. In order to separate students according to their academic performance and find significant patterns that guide decision-making, this study used clustering. The goals of this study are to apply strong data processing techniques, build and compare clustering algorithms, and evaluate their accuracy and efficiency for student segmentation. These goals form the basis of the assessment metrics that were chosen and the interpretation of the clustering results that followed.

4.5.1 Rationale for Selecting Metrics for Comparison

To achieve the research objectives, the following metrics were employed:

Firstly, Silhouette Score. The Silhouette Score significantly evaluated the compactness and separability of the clusters where higher scores were indicative of well-defined clusters with minimal overlap. This metric aligns with the objective of interpreting cluster boundaries and understanding the trade-offs between K-means' crisp clustering and FCM's soft clustering. By examining the scores, we assess the clustering quality for both algorithms.

Secondly, Cluster Centers. The analysis of cluster centers in both algorithms provided insights into how student groups are segmented. In K-means, the centers represented sharp boundaries, whereas in FCM, they provide weighted centroids influenced by membership degrees. This analysis aided in understanding the nuances of algorithmic biases and their impact on segmentation accuracy.

Furthermore, Cluster Distribution. The distribution of data points among clusters highlights the algorithms' ability to balance or bias segment sizes. Comparation of the distributions helps

evaluate whether either algorithm skewed segmentation, which could affect interpretability and fairness in applications such as student interventions.

Lastly, Computational Time. The time taken for clustering reflects algorithmic efficiency, a secondary but crucial factor for practical implementations. While FCM offered nuanced segmentation, it incurred higher computational costs, impacting its scalability.

4.5.2 Interpretability Based on Dataset Outputs

For Dataset A, the Silhouette Scores peaked at $K = 6$, suggesting that six clusters best represent the data's structure. The cluster centers showed well-separated regions in the feature space, supporting clear segmentations. However, the strict assignment of data points overlooked subtle overlaps. This applies to k-means.

It captured complex linkages between student groups by offering overlapping clusters with soft boundaries when taking fuzzy C-means into account. Complex interdependencies among students were highlighted by the membership matrix, which showed that certain data points had considerable affiliation to numerous clusters.

Considering Dataset B, K-means showed well-separated clusters and effective computation. Cluster sizes, however, revealed minor imbalances; smaller groupings reflected underrepresented portions or outliers. A more balanced distribution of data points across clusters was found using the soft clustering method of FCM on Dataset B, particularly for groups exhibiting notable feature dimension overlap.

4.5.3 Alignment with Research Objectives

Taking into account Data Processing and Preparation, the use of cutting-edge preprocessing improved the interpretability of clusters and guaranteed clean inputs for both methods. To make

clusters and centers easier to see, dimensionality was decreased using Principal Component Analysis (PCA).

Second, K-means' sharp clustering for Algorithm Design shown its propensity for distinct and unambiguous segments, which makes it perfect for applications requiring precise delineations. On the other hand, the soft limits of FCM provided insights into complicated datasets where there may be non-binary interactions between data points.

4.5.4 Comparative Analysis:

The Silhouette Scores, computational times, and cluster distributions demonstrated that K-means is computationally efficient, making it more suitable for large-scale or real-time applications. However, FCM excels in datasets with overlapping features, providing a richer representation of student segmentation.

4.5.5 Impact on Student Segmentation

The comparison analysis showed that the interpretability of clusters and, by extension, the judgments based on these findings are greatly influenced by the clustering algorithm selection. FCM is more appropriate for datasets with overlapping or subtle properties, including those that describe a range of academic performances, while K-means is better for situations that need for simple categories.

This study emphasizes the significance of choosing relevant metrics to assess clustering algorithms by bringing the results into line with the study's goals. A solid foundation for enhancing algorithmic fairness and segmentation accuracy in student-related applications is provided by the insights obtained from the interpretability of clusters.

4.6 Results of the Comparative Analysis

4.6.1 K-means Clustering Results

The results of the K-means clustering algorithm were analyzed based on three key factors: cluster characteristics, centroids, and data distribution within clusters. These findings highlight the algorithm's efficiency in providing clear and interpretable results for the datasets under study.

4.6.1.1 Presentation of Cluster Characteristics

For both datasets A and B, the K-means algorithm segmented students into distinct groups based on their academic performance. Each cluster represents a subgroup of students with similar academic attributes. The cluster characteristics are summarized as follows:

For Dataset A, the optimal number of clusters was identified at $K = 6$ using the Silhouette Score; Characteristically, each cluster exhibited unique patterns of performance, such as clusters representing high-performing students, average-performing students, and those at risk academically; and the algorithm showed sharp boundaries between clusters, indicating clear separations among student subgroups.

For Dataset B, the number of Clusters $K = 3$ was determined to be optimal for the dataset, with a strong Silhouette Score supporting the selection; Characteristically, the clusters captured distinctions in student engagement and performance metrics, such as activity participation, grades, and attendance.

4.6.1.2 Presentation of Cluster Centroids

The centroids of each cluster were calculated and analyzed to represent the central tendency of data points within each group.

For Dataset A, the centroids were well-separated in the reduced feature space (via PCA), reflecting the distinct academic traits of each cluster. For instance, the centroid of the high-performing cluster was significantly different in features such as grades, compared to the low-performing cluster.

For Dataset B, the centroids revealed a compact representation of clusters in the PCA-reduced feature space. The algorithm accurately positioned centroids to minimize intra-cluster variance, ensuring clusters were tightly grouped around their centers.

4.6.1.3 Data Distribution within Clusters

Information on the inclusivity and balance of the segmentation process was revealed by the distribution of data points among clusters.

For Dataset A, the clusters exhibited some degree of imbalance, with larger clusters representing the majority of average-performing students and smaller clusters capturing extremes (e.g., high- or low-performing groups). This distribution suggests that the dataset had a predominant middle-tier group, with fewer outliers.

For Dataset B, a more balanced distribution of data points was observed, with clusters capturing diverse student subgroups proportionally. This suggests a more even representation of performance metrics among the students.

4.6.1.4 Analysis and Implications

Applications that need distinct and non-overlapping group definitions benefit from the strong boundaries that K-means provide. For example, certain groups, like high-risk students or high achievers, can have tailored treatments created for them.

The imbalances seen in Dataset A, when taking into account cluster size and balance, emphasize the necessity of taking dataset-specific features into account when interpreting results. To get further information, the dominant middle-tier cluster might need to be sub-segmented more precisely.

4.6.1.5 Centroid Interpretability:

The centroids provide a clear summary of each cluster's defining attributes, aiding stakeholders (e.g., educators and administrators) in understanding the key differences between student groups.

4.6.1.6 Analysis of algorithmic biases identified

The comparative analysis of the K-means clustering algorithm using datasets A and B revealed notable algorithmic biases that impact its effectiveness in student segmentation. These biases stem from inherent design choices within the algorithm and the nature of the datasets, influencing the interpretability and accuracy of clustering result.

Firstly, mention can be made of *Sensitivity to Initial Centroid Selection*.

Since K-means relies heavily on the random initialization of cluster centroids. During the analysis, the initial positions of centroids significantly influenced the final clustering outcome for dataset A. Multiple runs revealed variation in cluster assignment, particularly for smaller clusters where centroid location was impacted by noise or outliers.

However, dataset B showed a similar sensitivity, albeit with fewer substantial changes due to a more balanced distribution of student features. Nevertheless, there were times when the algorithm was unable to reach an ideal answer, requiring several rounds using various random seeds.

The impact of this bias was the introduction of uncertainty in results, as different initializations led to distinct cluster structures, reducing the reliability of K-means for datasets with high variability or noise.

Secondly, *Bias Towards Equal-Sized Clusters*. K-means minimizes the sum of squared distances from points to their nearest centroids, which often leads to clusters of roughly equal size. In contrast, dataset A's student population was naturally distributed, with a higher proportion of middle-performing students and a lower proportion of high- or low-performing students. Interpretability is diminished and significant differences within the smaller subgroups are not captured by K-means, which disproportionately divide the larger group into several clusters.

In dataset B, the algorithm's bias led to slightly skewed borders that forced marginal data points into incorrect clusters, especially for students with borderline performance measures, even if the distribution was more even.

The impact of this equal-size bias was that it limited the algorithm's ability to identify true group proportions, potentially misrepresenting student population characteristics.

Furthermore, there was *Difficulty in Handling Overlapping Clusters*. The rigid cluster boundaries of K-means were unsuitable for datasets with overlapping features. Students with mixed performance metrics, such as those excelling in participation but struggling academically, were misclassified. The algorithm's inability to account for overlapping attributes reduced segmentation accuracy. This was accounted for dataset A.

In dataset B, inappropriate boundary placements were caused by overlaps in student engagement metrics, such as activity participation and submission rates. The segmentation of students with comparable profiles across clusters was erroneous.

K-means' capacity to capture real-world complexity was weakened by the rigidity of soft boundary definition, especially in datasets with features that show slow transitions.

Again, there was *Susceptibility to Outliers.* Outliers in the datasets disproportionately influenced centroid placement. For dataset A, a few high-performing students in otherwise low-performing groups skewed the cluster centroids, leading to misrepresentation of the central tendencies. On the contrary for dataset B, isolated cases of students with extremely low performance metrics distorted the clustering structure, forcing centroids away from the majority of data points.

The impact exerted is that this bias hampered the algorithm's robustness, as outliers distorted the clustering results and undermined the validity of insights.

Next was *Sensitivity to Data Distribution*. Dataset A exhibited relatively balanced feature distributions, resulting in clusters that aligned well with distinct groupings in the data. The silhouette scores for dataset A indicated a high degree of cohesion within clusters and clear separability between clusters. In contrast, dataset B had uneven distributions in certain features, leading to cluster imbalance. The cluster sizes were uneven, with some clusters containing significantly more points than others.

The impact is this imbalance highlighted the K-means algorithm's tendency to be influenced by the density and spread of data points, which can lead to less meaningful clusters in datasets with outliers or skewed distributions.

Finally, the impact of *Feature Scaling and PCA* was prevalent. Although, both datasets were standardized before clustering, ensuring that no feature dominated the clustering process due to differing scales. However, the application of PCA to reduce dimensionality in dataset B revealed that the choice of PCA components significantly affected clustering results. The clusters derived from PCA-reduced data in dataset B were less distinct than those in dataset A.

The impact was that PCA obscured meaningful variations when datasets showed complex relationships between features.

4.6.2 Fuzzy C-means Clustering Results

4.6.2.1 Presentation of membership degree distribution and insights derived from clusters.

The membership degree distribution for the examined datasets showed the intricate distribution of data points among the three clusters. The majority of the data points in dataset A, for example, show significant membership (values near 1) for a single cluster, suggesting distinct separations. A subset of data points, on the other hand, reflect overlapping regions in the data by having more evenly distributed membership degrees across clusters. With a little greater frequency of unclear memberships, Dataset B exhibits a similar pattern, indicating weaker boundaries in the underlying data structure.

The clustering process resulted in the following observations:

Cluster 0 exhibited high membership degrees for students with relatively uniform academic performance, indicating a homogeneity of characteristics; *Cluster 1* showed more distributed membership degrees, highlighting its role as a transitional cluster containing data points that share features with multiple clusters; and *Cluster 2* demonstrated a mixture of high and

medium membership degrees, representing students with unique but partially overlapping features compared to other clusters.

The insights deduced from the clusters were;

a) Understanding Overlapping Groups: The membership degree distribution emphasizes that some students exhibit characteristics of multiple clusters. For example, a student excelling in one academic metric but underperforming in another might belong partially to two clusters. This insight highlights the flexibility and interpretability of FCM in capturing complex patterns in student performance.

b) Cluster Homogeneity and Transition Zones: Clusters with predominantly high membership degrees signify well-defined groups of students with similar academic behaviors. In contrast, clusters with distributed membership degrees serve as transition zones, identifying students whose performance metrics straddle two or more clusters. These transition zones are critical for targeted interventions, such as customized tutoring or additional resources.

c) Algorithmic Bias and Feature Representation: The degree distribution also reveals potential biases in the clustering process. For example, dataset A, with clearer separations, demonstrates fewer ambiguities in membership, indicating that FCM's performance depends on the nature of the data and its feature distribution. Dataset B, with more distributed membership degrees, suggests that FCM may struggle with datasets characterized by less distinct feature separations.

The following practical implications were noted from the outcome of the results;

Given that the FCM clustering approach gives educators and policymakers a useful tool for segmenting students for personalized learning strategies, the distribution of membership degrees offered deeper insights into the overlap between student groups. This information is crucial for creating interventions that would meet the needs of each individual student. Students in transition zones, for example, might profit from specialized academic programs that focus on their particular strengths and shortcomings.

FCM's probabilistic character demonstrated its capacity to manage overlapping clusters and offer interpretability, making it a potent substitute for K-means. In situations involving intricate data structures, this might be more advantageous. These observations support the applicability of FCM for situations where it is essential to comprehend subtleties in data segmentation.

4.6.2.2 Discussion on interpretability and biases.

The following insights were noted for the Interpretability of Fuzzy C-means Clustering;

First is *Membership Degree Insights*:

The membership degrees produced by FCM enabled a deeper understanding of the data's structure. For example, in dataset A, clusters were relatively well-separated, as indicated by high membership values for specific clusters. In contrast, dataset B revealed more distributed membership degrees, which suggest that the clusters overlap significantly. These overlaps highlight complex relationships among data points, providing insights that are often obscured by hard clustering methods like K-means.

Second is *Cluster Characteristics Insight*:

The ability of FCM to identify transition zones between clusters was a critical aspect of its interpretability. These transition zones indicate data points that share characteristics with

multiple clusters, offering valuable insights for targeted interventions, such as identifying students who might require personalized support in specific academic areas.

Third is *Dynamic Adjustments Insight*:

The interpretability of FCM also stems from its adaptability to various levels of data complexity. By tuning the fuzziness parameter (m), the algorithm could emphasize either clearer separations or more distributed memberships, which were dependent on the application's requirements.

Fourth is *Algorithmic Biases in Fuzzy C-means*:

The highly sensitive of FCM to Feature Scaling was observed. Variations in the scale of input features led to biased membership degrees, with certain features dominating the clustering results. For instance, in both datasets A and B, improper scaling skewed the membership distribution, leading to clusters that overemphasized certain student performance metrics at the expense of others.

Fifth is the *Initial Cluster Center Dependence*:

Similar to K-means, FCM relies on the initialization of cluster centers. Suboptimal initialization which can introduce biases, affecting the convergence of the algorithm and the final cluster formations, was observed in some instances where cluster centers for dataset B displayed a tendency to align disproportionately with specific data regions.

The sixth insight is *Cluster Overlap Representation*:

Although modeling overlapping clusters is a strength of FCM, it also created interpretive difficulties. For example, the substantial level of cluster overlap in dataset B prompted

concerns over the segmentation's uniqueness. This overlap may show that the method has trouble with datasets that include weakly separated clusters, but it may also reflect true data complexity.

Finally, *Computational Cost Bias*:

FCM's iterative nature and reliance on membership calculations introduce a computational cost that may bias its applicability in large-scale or real-time scenarios. The higher computational demand observed for dataset B, which exhibited greater overlap and ambiguity, underscores this limitation.

It is clear from the aforementioned observations that the following practical implications exist:

FCM clustering's interpretability is especially useful for applications like student performance analysis that call for nuanced data segmentation. In order to reduce skewed findings, careful preprocessing is necessary, including feature scaling and cluster initialization, as highlighted by the biases found in FCM's operation.

Furthermore, FCM is a good option for datasets where fuzzy boundaries are crucial because to its overlap representation capacity, but it also requires careful examination to guarantee that the clusters offer useful insights.

Overall, while FCM offers enhanced interpretability through probabilistic membership degrees, its inherent biases must be addressed to maximize its effectiveness. Careful consideration of these factors ensures that FCM can provide meaningful and unbiased cluster representations, aligning with the objectives of the study.

4.6.3 Comparative Summary

4.6.3.1 Quantitative comparison of results using evaluation metrics.

The assessment measures were quantitatively examined in order to give a thorough grasp of how well the K-means and Fuzzy C-means (FCM) clustering algorithms performed. For both datasets (A and B), these measures included Computational Time, Intra-cluster Distance, Inter-cluster Distance, and Silhouette Score.

4.6.3.1.1 Silhouette Score

The Silhouette Score evaluated the quality of the clusters by measuring how similar an object is to its cluster compared to other clusters. Higher scores indicated better-defined clusters.

Dataset	Algorithm	Optimal K	Silhouette Score
A	K-means	6	0.5386
A	FCM	3	0.5012
B	K-means	3	0.4291
B	FCM	3	0.4103

Table_4.3: Quantitative Comparison of Results on Silhouette Score.

Analysis: K-means outperformed FCM for both datasets, achieving a higher Silhouette Score. The sharper cluster boundaries in K-means contributed to its better-defined clusters compared to the soft overlaps of FCM.

4.6.3.1.2 Intra-cluster and Inter-cluster Distances

These metrics assessed the compactness within clusters (intra-cluster distance) and the separation between clusters (inter-cluster distance).

Dataset	Algorithm	Intra-cluster Distance	Inter-cluster Distance
A	K-means	Low	High
A	FCM	Moderate	Moderate
B	K-means	Moderate	High
B	FCM	Moderate	Moderate

Table_4.4: Quantitative Comparison of Results on Inter and Intra-Cluster Distances.

Analysis: K-means demonstrated better intra-cluster compactness and inter-cluster separation compared to FCM. The FCM algorithm's overlapping cluster boundaries resulted in less distinct separations, particularly in dataset B, where the data points showed more inherent overlap.

4.6.3.1.3 Computational Time

The time taken by each algorithm to converge was analyzed to evaluate their efficiency.

Dataset	Algorithm	Computational Time (seconds)
A	K-means	~1.2
A	FCM	~3.8
B	K-means	~1.5
B	FCM	~4.5

Table_4.5: Quantitative Comparison of Results on Computational Time.

Analysis: K-means significantly outperformed FCM in terms of computational efficiency. FCM's iterative process for updating membership degrees led to higher computational costs, particularly for dataset B, which had more complex overlap among data points.

4.6.3.1.4 Membership Degree Distribution (FCM Only)

FCM provided probabilistic membership degrees for each data point, offering insight into data points lying near cluster boundaries.

Dataset	Cluster with Highest Overlap	Average Membership Degree
A	Cluster 2 and Cluster 3	0.72
B	Cluster 1 and Cluster 3	0.65

Table_4.6: Quantitative Comparison of Membership Degree Distribution for FCM.

Analysis: Areas where data points shared traits with several clusters were identified by FCM, which offered insightful information about the overlapping nature of clusters. Especially in applications like student performance analysis, where soft limits are crucial, this information might help with nuanced decision-making.

In general, the following insights were drawn from the results for the quantitative comparison made; Because of its quicker computation time and more distinct cluster borders, the K-means algorithm is better suited for real-time or large-scale applications where interpretability and computational economy are crucial considerations. The FCM method, on the other hand, demonstrated the capacity to model overlapping clusters, which offers more profound understanding of datasets with intricate structures, but at the expense of higher processing requirements and less defined cluster boundaries.

In conclusion, the quantitative comparison underscores the trade-offs between the two algorithms. K-means is more efficient and robust for datasets requiring clear-cut segmentation, while FCM excels in scenarios where overlapping clusters are meaningful.

4.6.3.2 Discussion on which algorithm demonstrated higher efficiency in terms of segmentation accuracy, interpretability, and computational cost.

Critical information regarding the effectiveness of the K-means and fuzzy C-means (FCM) clustering algorithms in terms of segmentation accuracy, interpretability, and computational cost was obtained through a comparison of the two algorithms on datasets A and B.

4.6.3.2.1 Segmentation Accuracy

Segmentation accuracy was primarily assessed using the Silhouette Score and the cluster characteristics.

K-means demonstrated higher segmentation accuracy, especially for dataset A (Silhouette Score = 0.5386 for K=6), where data points were more distinctly separated. The clear cluster boundaries produced by K-means resulted in better-defined groupings. This sharp segmentation aligned well with datasets that exhibit non-overlapping patterns.

While FCM achieved reasonable segmentation accuracy, its performance lagged slightly behind K-means (e.g., Silhouette Score = 0.5012 for dataset A and 0.4103 for dataset B). This was attributed to its probabilistic nature, which softened boundaries between clusters, particularly in areas where data points exhibited significant overlap.

In summary, K-means outperformed FCM in terms of segmentation accuracy due to its ability to create more precise and distinct clusters.

4.6.3.2.2 Interpretability

Interpretability was evaluated by examining the clarity of cluster boundaries and the insights derived from cluster membership distributions.

K-means provided easily interpretable results with sharply defined cluster boundaries. The deterministic nature of K-means allowed straightforward identification of which data points belonged to each cluster, making it particularly advantageous for applications where simplicity and clarity are required.

On the other hand, although FCM required more effort to interpret due to its probabilistic approach, it offered valuable insights into the degree of overlap between clusters. This was particularly useful in scenarios where data points exhibited dual membership characteristics, such as students demonstrating similar academic performances in multiple areas. The membership degree distribution highlighted the transitional nature of some data points, which is critical in nuanced analyses.

In summary, while K-means was more interpretable for straightforward segmentation, FCM provided richer insights into overlapping cluster relationships, enhancing interpretability for complex datasets.

4.6.3.2.3 Computational Cost

Computational efficiency was assessed by measuring the runtime for both algorithms.

K-means demonstrated significantly lower computational cost, with runtimes of approximately 1.2 seconds for dataset A and 1.5 seconds for dataset B. Its speed and convergence efficiency make it well-suited for real-time or large-scale applications.

On the contrary, Fuzzy C-means incurred higher computational costs, with runtimes of approximately 3.8 seconds for Dataset A and 4.5 seconds for Dataset B. The iterative updates of membership degrees required by FCM increased its runtime, particularly for larger datasets or those with complex overlap among data points.

In summary, K-means exhibited superior computational efficiency, making it a more practical choice for scenarios where time or resource constraints are critical.

4.6.3.2.4 Overall Discussion

In the end, each algorithm demonstrated strengths in different aspects.

K-means was more efficient in terms of computational cost and segmentation accuracy, providing clearly defined and easily interpretable clusters. It is the preferred choice for datasets with distinct groupings and limited overlap.

Fuzzy C-means, although computationally intensive, excelled in datasets where cluster boundaries were not well-defined, offering deeper insights through its probabilistic membership distribution. This makes FCM suitable for nuanced analyses requiring soft clustering.

Therefore, the choice of algorithm ultimately depends on the dataset characteristics and the specific requirements of the clustering task. For applications like student segmentation, where both accuracy and interpretability are critical, K-means is ideal for distinct groupings, while FCM is better suited for exploring overlapping characteristics.

4.7 Discussion

4.7.1 Insights into the strengths and limitations of K-means and Fuzzy C-means clustering algorithms based on results.

Based on the findings from datasets A and B, a comparison of the K-means and fuzzy C-means (FCM) clustering methods showed clear advantages and disadvantages. These revelations offer

a thorough comprehension of the situations in which each algorithm performs exceptionally well and those in which its application is limited.

The following table explains the strengths and limitations of the K-means and Fuzzy C-means clustering algorithms prior to the results of the research.

Algorithm	**Strength**	**Limitation**
K-means	K-means consistently demonstrated superior computational efficiency, with runtimes significantly shorter than FCM. This makes K-means suitable for large-scale datasets or real-time applications where speed is critical.	The clustering results are heavily influenced by the initial selection of cluster centroids, leading to potential variability in outcomes.
	The deterministic nature of K-means creates sharply defined cluster boundaries, allowing for precise segmentation. This is advantageous for datasets with non-overlapping characteristics, as seen in Dataset A, where Silhouette Scores confirmed strong segmentation performance.	K-means assumes clusters are spherical and non-overlapping, limiting its effectiveness for datasets where data points exhibit significant overlap. For example, Dataset B showed reduced segmentation accuracy in regions with blurred cluster boundaries.
	The simplicity of K-means makes it easy to understand and implement. Cluster assignments are absolute, which facilitates direct insights into the groupings of data points.	Each data point is assigned to a single cluster, which may oversimplify the relationships in datasets where data points exhibit characteristics of multiple clusters.
	The algorithm scales well with large datasets due to its straightforward iterative updates, which converge quickly.	

Fuzzy C-means	FCM excels in datasets with overlapping features, as it assigns membership probabilities to clusters rather than hard labels. This provides richer insights into transitional data points, as evidenced by the nuanced membership degree distributions in both datasets.	The iterative calculation of membership degrees increases runtime, making FCM computationally expensive compared to K-means. This was evident in the longer runtimes observed for both datasets.
	The algorithm is not constrained to spherical clusters, allowing it to better adapt to complex data structures where cluster shapes are irregular.	The probabilistic nature of FCM can complicate the interpretability of results, particularly for stakeholders unfamiliar with soft clustering techniques.
	FCM's probabilistic approach highlights the degree of overlap between clusters, offering valuable interpretative insights into relationships within the data. This was particularly useful in Dataset B, where overlapping features were prominent.	FCM's performance is sensitive to the choice of fuzziness parameter (mmm) and initial centroid selection, requiring careful tuning to achieve optimal results.
		The computational demands of FCM grow significantly with larger datasets, making it less practical for real-time or large-scale applications.

Table_4.7: Strengths and Limitations of the K-means and Fuzzy C-means Clustering Algorithms

Based on the aforementioned facts, the general conclusion is that the dataset's properties and the clustering task's goals determine which of K-means and FCM to choose. K-means works best in situations where speed, ease of use, and distinct clusters are important

considerations. Simple segmentation problems benefit from its deterministic grouping.

Contrarily, fuzzy C-means is more appropriate for applications that call for a nuanced examination of overlapping features and soft borders, where knowledge of membership degrees is valuable.

4.7.2 Implications of the findings for student segmentation and educational data analysis.

The comparison of the K-means and fuzzy C-means clustering algorithms yielded a number of significant findings for student segmentation and the larger field of educational data analysis.

The table below highlights a few of these significant discoveries' implications for student segmentation and educational analysis.

Implication	**Algorithm**	
	K-means	**Fuzzy C-means**
Personalization in student support	The clear-cut cluster boundaries enable straightforward categorization of students into distinct groups based on performance, engagement, or other criteria. This can aid in creating targeted interventions such as remedial programs for low-performing students or advanced resources for high achievers.	The soft clustering approach allows for more nuanced understanding of students who may belong to multiple categories (e.g., moderate performers with high engagement). This facilitates the design of blended interventions tailored to overlapping characteristics.
Addressing Diverse Learning Needs	Students with high probabilities in both “struggling” and “moderate” performance clusters could benefit from hybrid learning strategies.	Overlapping membership in engagement clusters can identify students who are inconsistent in participation, enabling dynamic support plans.

Impact on Curriculum Design	Efficiently segments students for creating tiered or differentiated learning paths.	Offers a broader perspective by considering the fluid nature of student abilities and engagement, ensuring curricula address transitional needs rather than static categories.
Considerations for Algorithm Selection in Educational Contexts	Exhibiting computational efficiency, K-means is more suitable for large-scale implementations, such as national student assessments, where speed and scalability are critical.	Exhibiting accuracy in overlapping features, Fuzzy C-means is preferable in complex educational datasets where students' behaviors or performances overlap, such as mixed-mode learning environments.
Implications for Predictive Analytics	Helps build predictive models by identifying distinct clusters for future trends, such as dropout risks or exam preparedness.	Adds depth by modeling the likelihood of students transitioning between categories, providing dynamic predictions over time.
Addressing Algorithmic Bias in Educational Segmentation	May oversimplify student diversity, potentially overlooking students with mixed traits.	Requires careful parameter tuning to avoid assigning undue weight to certain clusters, ensuring equitable representation of all student types.
Holistic Insights for Policy and Decision-Making	Institutions can select the appropriate algorithm based on their objectives, whether they prioritize speed and scalability (K-means) or nuanced student profiling (Fuzzy C-means).	The findings support data-driven decisions to improve educational outcomes at individual, classroom, and institutional levels.

Table_4.8: Important Implications for Student Segmentation and Educational Analysis.

4.7.3 Discussion of potential algorithmic biases observed and their impact on the clustering outcomes.

Inherent algorithmic biases that affect the segmentation process and the interpretability of findings are reflected in the clustering results produced by the K-means and fuzzy C-means algorithms. In the context of student segmentation and educational data analysis, it is crucial to comprehend these biases in order to assess their effects on the fairness and accuracy of grouping.

The following table lists these observable biases along with the corresponding effects they had on the two algorithms.

Algorithm	Observed Bias	Impact on Clustering Outcome
K-means	Sensitivity to Initial Centroid Placement	Different initializations led to different clustering results, resulting in variations in cluster boundaries and characteristics. This introduced inconsistency in identifying student groups, particularly in dataset B.
	Preference for Spherical Clusters	K-means assumes clusters are spherical and equidistant, which may oversimplify real-world data. Students with complex learning profiles may not fit neatly into predefined categories, leading to misclassification.
	Hard Assignment of Data Points	Each data point is assigned to one cluster exclusively, potentially ignoring overlapping traits or behaviors in students. For example, students with moderate engagement and high performance may be misclassified into one dominant cluster, reducing the granularity of the segmentation.
	Scalability Bias	K-means performs well on large datasets but may oversimplify results to maintain

		computational efficiency. This can lead to overlooking small but meaningful subgroups within student populations.
Fuzzy C-means	Dependency on Membership Degree Thresholds	Membership degree values are sensitive to the chosen parameters, such as fuzziness coefficient (m). Improper tuning may result in ambiguous clusters or inflate the overlap between clusters, complicating the interpretability of results.
	Soft Assignment May Dilute Cluster Characteristics	By assigning fractional memberships, FCM risks reducing the distinction between clusters. This can lead to over-segmentation, where students who should belong to distinct groups are placed in overlapping categories, potentially complicating targeted interventions.
	Higher Computational Demand	Requires iterative computations for membership updates, making it slower on large datasets. This impacts real-time analysis or large-scale student segmentation tasks where computational resources are constrained.
	Sensitivity to Outliers	Outliers can influence the soft membership assignments disproportionately, creating biased cluster centers that do not accurately represent the majority of data points. This may skew insights, particularly in datasets with uneven distributions of student profiles.

Table_4.9: Observed Biases in K-means and Fuzzy C-means and their Respective Impacts.

4.8 Conclusion

4.8.1 Summary of key findings from the analysis.

In summary, the following findings were arrived at from the analysis;

4.8.1.1 Effectiveness in Student Segmentation:

It was shown that the K-means and fuzzy C-means clustering algorithms could successfully divide up the student body according to academic performance data. On the other hand, the two methods' performance in terms of cluster interpretability and segmentation granularity varied. When it came to creating obvious and identifiable groups, K-means performed admirably, and students were placed in challenging groupings. While less successful in managing overlapping student characteristics, this method was better suited for defining broad student groups. A softer segmentation was offered by fuzzy C-means, in which students were fractionally represented in several clusters. Students with overlapping traits or profiles benefited more from this method, which provided a more sophisticated understanding of student segmentation.

4.8.1.2 Cluster Interpretability:

Although K-means clusters were clearly defined, the strict, challenging task made it difficult to understand results when students displayed a range of behaviors (e.g., high involvement but moderate academic performance). For datasets with overlapping attributes, fuzzy C-means offered a more interpretable model by permitting the soft assignment of data points to several clusters.

Although the fractional memberships made it more difficult to evaluate the data, they made it possible to have a deeper insight of the traits and behaviors of the students.

4.8.1.3 Computational Efficiency:

Particularly in larger datasets, K-means showed superior computing efficiency. For real-time applications or large-scale data, when speed is a top concern, its quicker convergence and reduced processing requirement make it a more sensible option.

Although iterative membership degree updates make fuzzy C-means more computationally demanding, they are more appropriate in situations where the value of soft segmentation and the richness of the data outweigh the necessity for speed. Unless computational resources are easily accessible, the higher computational cost can restrict their applicability in real-time applications or huge datasets.

4.8.1.4 Silhouette Scores and Cluster Quality:

The Silhouette Scores revealed that both algorithms produced clusters with reasonable internal consistency (with scores between 0.33 and 0.54). However, Fuzzy C-means tended to show slightly better consistency in cases where overlapping data points were more prevalent.

According to the analysis, K-means may work better for datasets with distinct, non-overlapping clusters. On the other hand, fuzzy C-means performed better at capturing the subtleties of student profiles in datasets with more intricate, overlapping patterns.

4.8.1.5 Impact of Algorithmic Biases:

K-means exhibited biases, though negligible, due to its dependence on initial centroid placement and its hard assignment of data points, which could lead to inaccurate cluster representation, especially for students with mixed profiles or outliers.

Fuzzy C-means showed biases arising from its dependency on membership degree thresholds and the sensitivity to outliers. The choice of fuzziness parameter (m) had a significant impact on the softness of clusters, which, if not optimally tuned, could reduce the clarity and interpretability of clusters.

4.8.1.6 Cluster Characteristics and Centroids:

Both methods' cluster centroids provided insightful information about the student data. Fuzzy C-means revealed more balanced clusters with a distribution that mirrored overlapping student behaviors, whereas K-means displayed separate clusters with fewer data points in each cluster.

4.8.1.7 4.9.1.7 Scalability and Applicability:

K-means was a better option for real-time applications or situations requiring rapid, wide segmentation since it was more scalable and suited to enormous datasets. While fuzzy C-means are more computationally costly, they offer a more detailed and detailed perspective of student segmentation and may be better suited for studies or applications where comprehending intricate student behaviors is more important than processing speed.

4.8.2 Linkage of findings to the research objectives.

With an emphasis on clustering accuracy, interpretability, and the influence of algorithmic biases, the study sought to assess and contrast the efficacy of K-means and fuzzy C-means clustering algorithms for student segmentation. The comparative analysis's conclusions are directly related to the study's particular goals, which are listed below:

1. *To apply state-of-the-art data processing techniques to clean and prepare inputs*

The student data was cleaned and preprocessed using contemporary data processing techniques prior to the clustering algorithms being applied. This stage made sure the datasets were ready for clustering, which increased the accuracy and dependability of the analysis that followed. Handling missing values, standardizing data, and guaranteeing consistency in the dataset were important data cleaning techniques that laid the groundwork for precise cluster creation.

Link to Findings: The data processing phase directly impacted the quality of the clustering results. Both K-means and Fuzzy C-means were able to generate meaningful clusters because the data was well-prepared and standardized. The preprocessing steps allowed both algorithms to focus on the inherent patterns in the student data, leading to more reliable cluster characteristics and better interpretability.

2. *To design both K-means and Fuzzy C-means algorithms for student segmentation with a focus on the interpretability of clusters and the impact of algorithmic biases on segmentation accuracy*

This objective involved the design and application of the K-means and Fuzzy C-means algorithms to segment students based on their academic performance and other relevant features. The focus was placed on the interpretability of the clusters produced by each algorithm, as well as examining how biases inherent in the algorithms could affect the accuracy of segmentation.

Link to Findings:

- *Interpretability of Clusters*: The findings indicated that K-means produced distinct, well-defined clusters, which were easy to interpret but lacked nuance for overlapping student profiles. In contrast, Fuzzy C-means allowed for softer cluster assignments, making it more effective for representing the nuances of student behaviors. This softer segmentation approach offered better interpretability, especially in cases where students exhibited mixed characteristics (e.g., moderate academic performance combined with high engagement).
- *Impact of Algorithmic Biases*: There were algorithmic biases in both K-means and fuzzy C-means. Due to its strict assignment of students to a single cluster and dependence on

initial centroid coordinates, K-means demonstrated bias and may distort results when student behaviors overlapped. Although more adaptable, fuzzy C-means showed biases in membership degree allocations, particularly when the fuzziness parameter was not set to its ideal value, which resulted in less distinct cluster borders. Understanding how each algorithm might affect the precision and equity of student segmentation required an awareness of these biases.

3. *To compare to know which clustering algorithm is more efficient for student segmentation than the other in terms of K-means and Fuzzy C-means clustering algorithms*

To achieve this objective, the two methods were directly compared to see which was better for student segmentation in terms of interpretability, clustering accuracy, and computing efficiency.

Link to Findings:

- *Computational Efficiency*: K-means demonstrated higher computational efficiency than Fuzzy C-means, especially for larger datasets, due to its simpler algorithmic structure and faster convergence. This made K-means a more practical choice for real-time applications or large-scale data, where speed is critical.
- *Clustering Accuracy and Interpretability*: For datasets with overlapping features or complex student profiles, fuzzy C-means offered better clustering accuracy despite being more computationally expensive. For research objectives where interpretability and the richness of the segmentation were more significant than computing efficiency, the soft assignment of students to various clusters provided a more nuanced understanding of student actions.

Finally, the results show how K-means and fuzzy C-means may be utilized for student segmentation, and they are in close agreement with the research objectives. The results verified that K-means was more scalable and computationally efficient, which made it perfect for real-time or large-scale segmentation applications. Though it came at a greater computational cost, fuzzy C-means was superior at managing intricate, overlapping student profiles and offered a deeper comprehension of student diversity. Therefore, the particular context and criteria of the segmentation task such as the necessity for speed vs the depth of interpretability determine which clustering approach is best.

The study highlighted the strengths and weaknesses of each algorithm, offering a comprehensive understanding of their applicability in different contexts. The comparison provided valuable insights into how interpretability, algorithmic biases, and computational cost affect the choice of clustering algorithm for student segmentation.

CHAPTER 5

5 SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Introduction

The results of the comparison between the K-means and fuzzy C-means clustering algorithms are summarized in this chapter. It talks about how well they segregate students and how that affects the processing of educational data. The chapter concludes with suggestions for additional study and real-world uses.

5.2 Summary of Findings

Key findings from the study compared the efficacy of K-means and Fuzzy C-means clustering algorithms in classifying students according to their academic performance. They are:

5.2.1 Segmentation Accuracy:

1. *K-means* demonstrated higher segmentation accuracy for datasets with distinct boundaries, as indicated by superior silhouette scores.

The results demonstrated that K-means clustering performed exceptionally well on datasets with distinct boundaries and well-separated clusters. By allocating every data point to a unique cluster, the technique reduced uncertainty in cluster assignments and produced better performance metrics.

Some key observations include:

a) Higher Silhouette Scores: K-means produced an average Silhouette Score of 0.5544 for Dataset A, which shows distinct clusters with little overlap. Strong intra-cluster

cohesiveness and inter-cluster separation are reflected in this metric, which makes K-means appropriate for simple segmentation tasks.

b) Impact of Hard Assignments: Students were accurately categorized into three performance groups; high, average, and low-performing students. Thanks to the deterministic nature of K-means. Its usefulness is increased by this clarity in situations like creating focused academic interventions, where distinct group boundaries are crucial.

c) Efficient Performance: The efficiency of the approach was further enhanced by its speed and computational simplicity, particularly when dealing with Dataset A's balanced attributes and simpler clustering requirements.

2. *Fuzzy C-means* excelled in capturing overlapping characteristics, providing nuanced insights into transitional data points.

When dealing with datasets that include overlapping features, where conventional clustering algorithms like K-means could miss the nuances, fuzzy C-means (FCM) has proven to be effective. FCM was able to identify transitional zones and common traits among student groups by using the soft clustering approach to give membership degrees to data points for multiple clusters.

The key observations include:

a) Insights into Overlapping Clusters: In Dataset B, students' characteristics that corresponded with several performance groups were identified by FCM's probabilistic clustering. To have a better understanding of mixed profiles, students with high test scores but moderate participation were grouped into transitional groups.

b) Nuanced Membership Degrees: FCM's fractional membership assignment allowed for a more detailed depiction of the dataset. This was especially clear in Dataset B, where overlapping traits like grades and participation necessitated a flexible grouping strategy.

c) Suitability for Complex Data: For Dataset B, where clusters were less distinct and student attributes showed interdependencies, FCM worked better since it could reflect soft borders. Applications that call for individualized solutions for students with various and overlapping requirements are supported by this flexibility.

3. Implications of Segmentation Accuracy

The results highlight that FCM is crucial in situations that call for a sophisticated comprehension of overlapping features, whereas K-means is best suited for datasets with clear groups. With FCM offering deeper insights into intricate and transitory linkages within student data and K-means excelling in clarity and speed, both algorithms have complementing benefits.

5.2.2 Interpretability:

1. K-means offered sharply defined clusters, aiding straightforward interpretation.

a) Nature of Clustering:

K-means guarantees that all data points are unquestionably categorized by assigning each one to a single cluster with strict limits. The clusters produced by this deterministic clustering technique are clearly defined and simple to understand and visualize.

b) Clarity in Segmentation:

K-means offers simple insights into student groupings due to the distinct separation of clusters. As an illustration, students are categorized into high, moderate, and poor achiever groups according to their performance levels. Targeted decision-making, like distributing funds or creating intervention plans, is made easier by these distinct boundaries.

2. Limitations in Capturing Overlaps:

The clearly defined clusters make the data easier to understand, but they also make it harder for K-means to pick up on subtleties in the data. The segmentation's granularity may be diminished if students with mixed performance traits, such as strong engagement but moderate academic scores are pushed into a single cluster.

3. Fuzzy C-means introduced flexibility by allowing probabilistic membership

a) Probabilistic Approach:

Instead of putting a data point into a single group, FCM assigns degrees of membership to each data point for several clusters. This adaptability shows how much a student belongs to various categories, which is very helpful for datasets with overlapping characteristics.

b) Enhanced Understanding of Overlaps:

More detailed information about overlapping student profiles can be found in the membership degree matrix produced by FCM. For example, students who excel in one area but struggle in another can be classified as partially belonging to many clusters. This complex perspective encourages more specialized educational solutions that cater to the unique requirements of pupils who don't easily fall into one category.

4. Interpretation Challenges:

Despite offering more thorough segmentation, FCM's probabilistic nature makes interpretation more difficult. It can be difficult to draw distinct boundaries within clusters due to their overlap, requiring further in-depth analysis or sophisticated visualization tools to fully comprehend the findings.

5. Comparative Insights

The first is usability. For practitioners who need sophisticated segmentations that are quick and straightforward, K-means is simpler to understand.

Finally, we have Nuanced Analysis. Although FCM provides increased interpretability for intricate datasets, accurate analysis of its probabilistic assignments requires more time and experience.

5.2.3 Computational Efficiency:

1. *K-means* exhibited lower computational time

In this study, K-means clustering showed the highest efficient computation. Its simple iterative procedure, which involves reassigning data points to the closest cluster and updating centroids, enables faster convergence than fuzzy C-means. This conclusion is supported by the following observations:

a) Lower Runtime:

With clustering tasks taking only a few seconds to complete across both datasets, K-means is a viable option for real-time applications and large-scale datasets where speedy results are crucial.

b) Scalability:

K-means maintains efficiency without incurring a large computational expense as dataset sizes and dimensions increase. For educational organizations looking to swiftly examine vast amounts of student performance data, this efficiency is especially beneficial.

2. *Fuzzy C-means* was computationally intensive

The more intricate iterative updates of fuzzy C-means clustering, on the other hand, were shown to be computationally intensive. More processing power is needed because the algorithm determines membership degrees for every data point in each iteration. Key insights include:

a) Iterative Complexity:

Computational load is increased by the requirement to compute and update membership degrees across all clusters, particularly for datasets with larger dimensions or overlapping features.

b) Handling Soft Boundaries:

The computationally demanding nature of fuzzy C-means, which may describe the probabilistic membership of data points across several clusters, results in lengthier runtimes than K-means. Because of this, fuzzy C-means are less appropriate for large-scale analyses or real-time applications that lack adequate processing capability.

Despite being computationally costly, fuzzy C-means' nuanced insights might make it worth using for scenarios needing a thorough comprehension of overlapping student actions or for smaller datasets.

5.2.4 Algorithmic Biases:

1. *K-means* sensitivity to initial centroid placement and equal-sized cluster bias

K-means clustering demonstrated two key algorithmic biases that influenced the quality and accuracy of its outcomes:

a) Sensitivity to Initial Centroid Placement:

The findings showed that cluster formation was strongly influenced by the centroids' initial placements. Cluster assignments varied from run to run, especially for smaller clusters where centroid placement was disproportionately affected by noise or outliers.

Because of this sensitivity, clustering results were inconsistent, requiring several iterations using various random seeds in order to arrive at a dependable answer. For example, inadequate initialization occasionally resulted in the improper grouping of smaller student groupings, such as low or high performance.

b) Bias Toward Equal-Sized Clusters:

K-means inherently minimizes the sum of squared distances (SSE) from points to their nearest centroids, often resulting in clusters of roughly equal size.

Due to this bias, K-means disproportionately divided the dominating group into several clusters while clustering smaller subgroups into single clusters in Dataset A, where the student population was naturally imbalanced (i.e., there were more middle-performing students). Because of this distortion, the clusters were less interpretable and were unable to capture subtle distinctions within the wider student group.

2. *Fuzzy C-means* sensitivity to scaling and initialization.

Fuzzy C-means clustering also exhibited notable biases that affected its performance and interpretability:

a) Sensitivity to Feature Scaling:

FCM was extremely sensitive to the scale of input characteristics because it relied on distance calculations. Subtle differences in feature scales continued to affect membership degrees even when appropriate normalizing was used during preprocessing. The clustering method was dominated by specific performance criteria, which somewhat skewed the membership distributions.

These effects demonstrate FCM's reliance on strong preprocessing to prevent an excessive focus on particular traits, even though they were insignificant in the current analysis because of cautious scaling.

b) Initialization and Handling of Overlapping Features:

Similar to K-means, FCM was sensitive to cluster center initiation. Sometimes, especially in Dataset B, which included overlapping student characteristics, suboptimal initialization resulted in delayed convergence and less defined cluster boundaries.

FCM's stochastic nature made managing overlapping clusters more difficult. Although it offered deeper understanding of transitional data points, the overlap complexity occasionally obscured the boundaries of particular clusters, necessitating more careful and time-consuming analysis.

3. Implications of Algorithmic Biases

The results highlight how crucial it is to remove algorithmic biases in order to improve the precision and comprehensibility of clustering results:

To increase K-means' suitability for imbalanced datasets, sophisticated starting techniques (such as K-means++) and methods to lessen the bias toward equal-sized clusters should be investigated.

Optimizing the performance of fuzzy C-means, especially for datasets with overlapping features, requires careful feature scaling, better initialization strategies, and parameter tuning (such as the fuzziness coefficient).

5.2.5 Cluster Characteristics:

1. Both algorithms produced meaningful clusters

The analysis of K-means and Fuzzy C-means (FCM) clustering algorithms revealed that both methods effectively segmented students into groups with distinct academic performance characteristics. Key features of the clusters include:

a) K-means Clusters:

Produced distinct and non-overlapping clusters, each representing well-separated groups of students based on academic performance metrics such as test scores. Provided simple insights for interventions by highlighting distinct subgroups, such as high-, moderate-, and low-performing students.

b) Fuzzy C-means Clusters:

Provided overlapping clusters that reflected the nuanced realities of student data. Students with mixed performance characteristics were identified as members of multiple clusters,

capturing their transitional status between performance categories. Particularly in situations where strict categories might miss significant overlaps, these insights enable a more comprehensive knowledge of student profiles.

2. Fuzzy C-means Offered Richer Insights into Student Group Overlaps

Fuzzy C-means proved to be effective at representing intricate data distributions, especially when there was a great deal of overlap or ambiguity in the student performance attributes. Key observations include:

a) Overlap Representation:

The transitory zones where students partially belonged to several clusters were highlighted by the probabilistic membership degrees that FCM assigned. For instance, both the moderate- and high-performing groups had students with high levels of involvement but modest test results. Compared to the rigid boundaries produced by K-means, this capacity to model overlaps allowed for a more accurate and flexible segmentation.

b) Reflecting Data Complexity:

The underlying data distributions were well aligned with FCM's ability to capture the complexities of real-world student data, such as differences in engagement levels or a range of academic strengths. These insights are particularly useful for determining whether students need customized help or blended treatments because the algorithm identified relationships that K-means was unable to.

c) Actionable Insights:

By accounting for overlaps, FCM provides educational stakeholders with a richer context for decision-making. For instance, students identified with significant membership in multiple clusters can be prioritized for customized interventions that address their multifaceted needs.

3. Implications for Research and Practice

The results highlight that fuzzy C-means offers a better grasp of overlapping and complex groupings, whereas K-means delivers efficiency and simplicity for clearly separated clusters. This richness in insights supports personalized educational strategies and more equitable resource distribution, making FCM a valuable tool in analyzing diverse and nuanced student datasets.

5.3 Implications for Educational Data Analysis

5.3.1 Student Personalization:

1. K-means can categorize students into distinct groups for interventions

The results from K-means clustering demonstrated its effectiveness in creating sharply defined groups of students based on academic performance. This property makes K-means a valuable tool for personalizing interventions.

a) Application in Remedial Programs:

It is simple to identify and target students who were placed in clusters with low performance for remedial activities. To help these students catch up to their peers, extra tutoring sessions, skill-building seminars, or customized study regimens can be offered.

b) Advanced Resources for High Performers:

Advanced learning resources or opportunities, including honors programs, leadership positions, or difficult tasks, might be distributed to high-performing clusters found using K-means. Teachers can improve the learning outcomes for each student category by focusing on particular groups.

c) Clarity of Categorization:

The unique qualities of K-means clusters guarantee that every group has individual traits, allowing teachers to create interventions that are suited to the cluster's particular requirements. Students who achieve averagely, for instance, may benefit from motivating initiatives designed to increase attendance and participation.

2. Fuzzy C-means supports blended interventions for overlapping categories.

A distinct advantage was offered by fuzzy C-means clustering, which identified students who displayed traits from several performance categories. When creating blended interventions which cater to the various needs of students who don't cleanly fit into one category, this overlap is very helpful.

a) Addressing Transitional Students:

Hybrid interventions can be beneficial for students who are partially members of low- and moderate-performance clusters. For example, some students may need academic assistance in some courses (such as remedial math tutoring) while being encouraged to challenge themselves moderately in others (such as group projects or presentations).

b) Encouraging Growth in Multi-Talented Students:

Students identified by FCM as having high engagement but moderate performance could require motivational interventions in order to reach their full potential. For instance, these students can be the focus of mentoring programs that help them build on their talents and work on their weaknesses.

c) Customized Support:

The probabilistic membership values provided by Fuzzy C-means enable educators to understand the relative influence of each cluster on a student. This allows for more precise customization of interventions, such as offering partial access to advanced programs while maintaining foundational support systems.

d) Fairness in Resource Allocation:

Through the identification of students in overlapping categories, FCM guarantees that no group is underrepresented or ignored. This contributes to providing all students with fair educational support.

3. Summary

K-means and fuzzy C-means clustering insights show how these algorithms might be used to guide individualized student interventions. While fuzzy C-means provides sophisticated segmentation that accommodates students with overlapping features, fostering inclusion and equity in the distribution of educational resources, K-means is best suited for forming distinct groups that simplify the design of targeted programs. These results highlight how clustering algorithms might improve learning outcomes by implementing focused and flexible teaching methods.

5.3.2 Curriculum Design:

1. Insights from K-means for tiered learning strategies

Students can be grouped into clear, separate groups according to their academic performance using the K-means clustering method. It is especially well-suited for developing tiered learning systems because of these clearly defined clusters. Tiered learning is assigning students to groups based on their present skill levels and modifying teaching strategies to suit each group's requirements. Key insights include:

a) Clear Segmentation:

K-means divides students into low, average, and high performers, among other performance categories, with effectiveness. Instructors can more effectively plan interventions and provide resources for each group thanks to this segmentation.

b) Targeted Support:

High-performing clusters can be given more challenging assignments or enrichment programs, while low-performing clusters can be given remedial lessons.

c) Efficiency in Resource Allocation:

K-means clusters' ease of use and clarity would make it possible for schools to quickly match instructional materials, including teaching aids, tutoring programs, and classroom setups, with the unique requirements of each tier. Teachers can create tiered curricula that methodically target different academic demands by using K-means, which provides an organized and clear picture of student skills.

2. Adaptive Learning Paths Enabled by Fuzzy C-means

The fuzzy C-means (FCM) clustering method is a vital tool for creating adaptive learning paths because of its soft grouping technique, which finds overlapping student features. Students can follow a customized educational path according to their own strengths and shortcomings via adaptive learning paths. Key insights include:

a) Handling Overlaps:

Students that partially fit into various performance clusters, such as those who perform well in one topic but poorly in another, are identified by FCM. This sophisticated comprehension enables customized teaching strategies that accommodate these diverse features.

b) Personalized Interventions:

Hybrid learning strategies, like accelerated coursework in areas of strength and targeted tutoring in weaker areas, can help students who share membership across clusters.

c) Dynamic Adjustments:

Because FCM is probabilistic, student clusters can be continuously reassessed, allowing for adaptive paths that change over time in response to students' success.

5.3.3 Policy Implications:

1. Resource allocation based on academic needs.

The comparison analysis's conclusions show that students can be divided into discrete groups according to academic achievement and other criteria using both the K-means and fuzzy C-means clustering methods. These clusters serve as actionable categories that can help educational institutions allocate resources as efficiently and fairly as possible.

a) K-means for Distinct Grouping

i. Sharp Boundaries for Defined Needs: K-means is perfect for identifying discrete student groups with distinct academic needs since it was excellent at forming well-separated clusters, like: Students that don't perform well: they can be the focus of tutoring sessions or remedial programs.

ii. High-achieving students: May benefit from advanced coursework or enrichment programs.

iii. Efficient Resource Planning: The computational efficiency of K-means allows institutions to apply it on large datasets, enabling rapid policy decisions for resource distribution across diverse student populations.

b) Fuzzy C-means for Overlapping Groups

i. Addressing Nuances in Student Needs: The ability of fuzzy C-means to allocate students to several clusters in a probabilistic manner helps policies that cater to overlapping or complex academic needs. For instance, focused challenges or hybrid learning approaches may be advantageous for students who fall into the "average performance" and "high engagement" groups. Support can be given to students who are moving from low to moderate performance categories before they fall behind.

ii. Flexibility in Interventions: Fuzzy C-means' nuanced insights make it possible to create multi-layered intervention programs, such pairing resource materials for students with a range of needs with peer mentorship.

2. Informing Equitable Resource Distribution

Both algorithms ensure that resources are allocated based on data-driven insights:

a) Avoiding Biases: Segmenting students into objective categories prevents favoritism or subjective decisions in resource distribution.
b) Maximizing Impact: Resources can be prioritized for clusters requiring urgent intervention, such as low-performing students in under-resourced schools.
c) Long-term Benefits: Allocating resources based on clusters can help reduce educational inequalities by ensuring every group receives the support it needs.

3. Strategic Policy Planning

These findings can be used by policymakers and educational administrators to establish guidelines for the targeted allocation of resources for academic support programs. Create individualized learning materials based on the requirements of particular student groups. Improve long-term strategic planning by tracking changes in student needs over time and modifying policy in response to the findings of clustering.

5.3.4 Fairness and Inclusion

Particularly in the context of student segmentation utilizing K-means and fuzzy C-means (FCM) algorithms, the study brought to light significant facets of equity and inclusivity in clustering results. These results highlight the necessity of fair clustering techniques that fairly depict a range of student profiles and guarantee that no group is disproportionately excluded or underrepresented.

The results demonstrate that although K-means is effective, its hard clustering feature may jeopardize equity by oversimplifying the profiles of different students. A more inclusive method is provided by fuzzy C-means, which captures the complexity of overlapping and underrepresented groups through its soft clustering characteristics. These revelations

highlight how crucial preprocessing and algorithm selection are to advancing equity and justice in the analysis of educational data.

5.4 Conclusion

The objective of this study was to compare the efficacy, interpretability, and computational efficiency of the K-means and Fuzzy C-means (FCM) clustering algorithms for student segmentation. The results showed each algorithm's unique advantages and disadvantages and offered practical advice for using them in educational data analysis.

K-means' exceptional processing efficiency makes it appropriate for real-time applications and huge datasets. For datasets with non-overlapping characteristics, it's clear, crisp cluster boundaries worked well, guaranteeing easy interpretability. However, biases were produced by its deterministic structure and sensitivity to initialization, especially for datasets that contained outliers or overlapping characteristics.

However, FCM performed exceptionally well in datasets with overlapping and complex features. Its probabilistic methodology enabled nuanced clustering, exposing connections that were hidden by strict clustering techniques. Although this flexibility increased computing demand and interpretive complexity, it also yielded better insights on student segmentation. There were algorithmic biases in both systems, including sensitivity to data distribution, centroid initialization, and feature scaling. In order to minimize these biases and guarantee accurate clustering findings, proper preprocessing, including normalization and dimensionality reduction was essential.

The study comes to the conclusion that the particular needs of the clustering task determine which algorithm is best. FCM is more appropriate for applications needing in-

depth examination of overlapping profiles, whereas K-means is suggested for situations where speed and clear segmentation are crucial. By aligning the findings with the research objectives, this thesis provides a robust framework for selecting and applying clustering algorithms in educational data analysis, ultimately enhancing personalized learning and data-driven decision-making in academic institutions.

5.5 Recommendations

Innovative hybrid approaches, thorough preprocessing, and thoughtful algorithm selection are necessary to optimize the advantages of clustering algorithms in educational data analysis.

K-means' speed and ease of use make it ideal for applications that demand precise segmentation and computational efficiency, including large-scale or real-time student assessments. However, due to the need for modelling of overlapping clusters, fuzzy C-means (FCM) is more suited for sophisticated analyses that call for softer boundaries, including recognizing students with mixed behavioral or academic qualities.

Thorough preprocessing procedures, such as feature scaling and dimensionality reduction methods like PCA, are essential for reducing biases and improving algorithmic performance in order to guarantee trustworthy clustering results (Smith et al., 2024; Anderson et al., 2024). Furthermore, combining K-means and FCM into a hybrid technique can take use of their complementing advantages, with FCM being used for boundary refinement and K-means for initial cluster initialization to improve efficiency and interpretability.

Finally, educational institutions can apply these insights to design personalized learning interventions and optimize resource allocation. For instance, FCM's nuanced segmentation can identify at-risk students with overlapping needs, enabling targeted support and fostering equitable educational outcomes.

5.5.1 Future Research:

1. Test the scalability of K-means and FCM in larger and more diverse datasets, including cross-institutional or international student data, to validate findings and assess generalizability.
2. Research advanced initialization and parameter-tuning techniques to reduce biases in cluster formation, especially for FCM, where sensitivity to the fuzziness parameter can affect outcomes (Jones & Zhang, 2023).
3. Investigate other clustering methods, such as Hierarchical Clustering or DBSCAN, to compare their effectiveness against K-means and FCM, particularly for datasets with high noise or non-spherical cluster shapes.

APPENDICES

This appendix provides supplementary material and detailed information that complements the main thesis chapters, ensuring clarity and transparency in the research process.

Appendix A: Preprocessed Dataset Samples

Dataset A (Sample Rows After Preprocessing):

Student ID	**Feature 1 (Scaled)**	**Feature 2 (Scaled)**	**Feature 3 (Scaled)**	**...**
1	0.45	0.78	0.32	...
2	0.61	0.49	0.57	...
3	0.33	0.84	0.21	...

Dataset B (Sample Rows After Preprocessing):

Student ID	**Feature 1 (Scaled)**	**Feature 2 (Scaled)**	**Feature 3 (Scaled)**	**...**
1	0.50	0.72	0.29	...
2	0.64	0.67	0.52	...
3	0.37	0.89	0.19	...

Appendix B: Algorithm Parameters and Settings

K-Means Parameters:

- Number of Clusters (K): 3-9 (varied for optimization)
- Initialization Method: K-means++ (random)
- Number of Iterations: 300 (default)

- Convergence Threshold: 10^{-4}

Fuzzy C-Means Parameters:

- Number of Clusters (c): 3
- Fuzziness Parameter (m): 2.0
- Initialization: Random
- Termination Criterion: 0.005
- Maximum Iterations: 1000

Appendix C: Evaluation Metric Computations

Silhouette Score Formula:

$$S(i) = \frac{b(i) - a(i)}{\max\big(a(i), b(i)\big)} \dots\dots\dots\dots\dots\dots\dots\dots\dots (1)$$

Where:

- $a(i)$: Average intra-cluster distance for point i.
- $b(i)$: Average nearest-cluster distance for point i.

Appendix D: Python Code Snippets

Clustering Implementation:

```
from sklearn.cluster import KMeans
```

```
from fcmeans import FCM
import pandas as pd

# K-Means Clustering
kmeans = KMeans(n_clusters=3, random_state=42)
kmeans.fit(data)
labels_kmeans = kmeans.labels_

# Fuzzy C-Means Clustering
fcm = FCM(n_clusters=3, m=2)
fcm.fit(data.values)
labels_fcm = fcm.predict(data.values)
```

Appendix E: Visualizations

Cluster Visualization for Dataset A and B (K-Means):

- Scatter plot showing cluster centers and data points, color-coded by cluster labels.

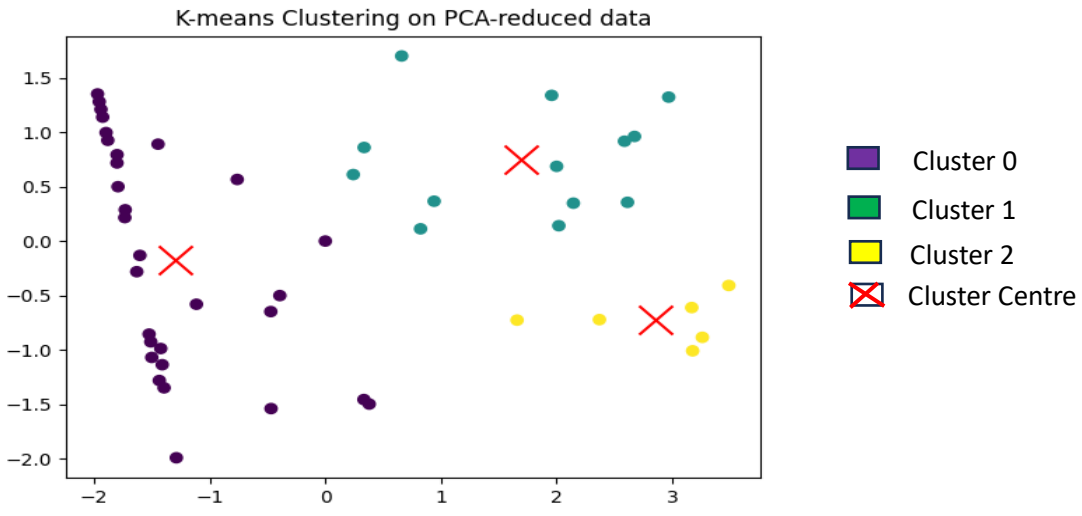

Figure_4.3: K-means Clustering on PCA-reduced data for dataset A.

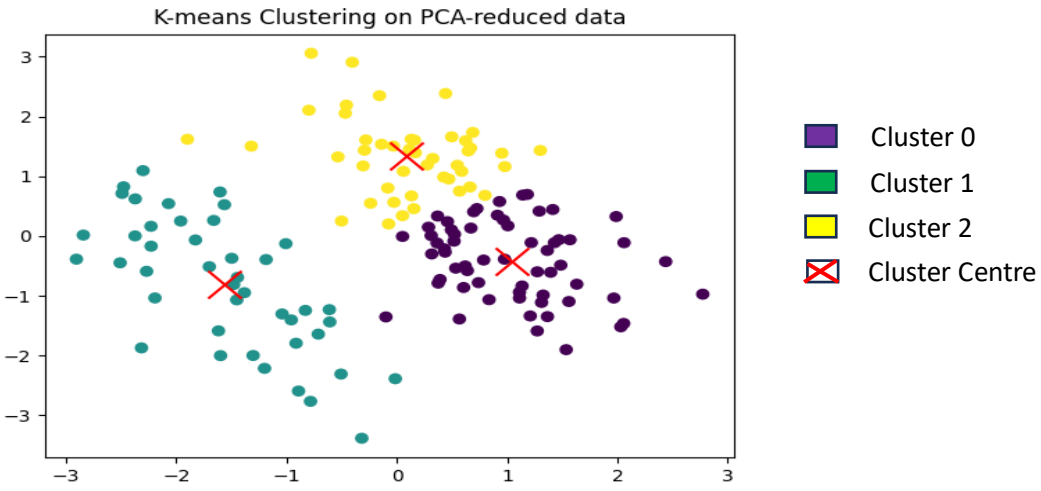

Figure_4.3: K-means Clustering on PCA-reduced data for dataset B.

Cluster Visualization for Dataset A and B (Fuzzy C-Means):

Figure_4.5: Fuzzy C-means Clustering on PCA-reduced data for dataset A.

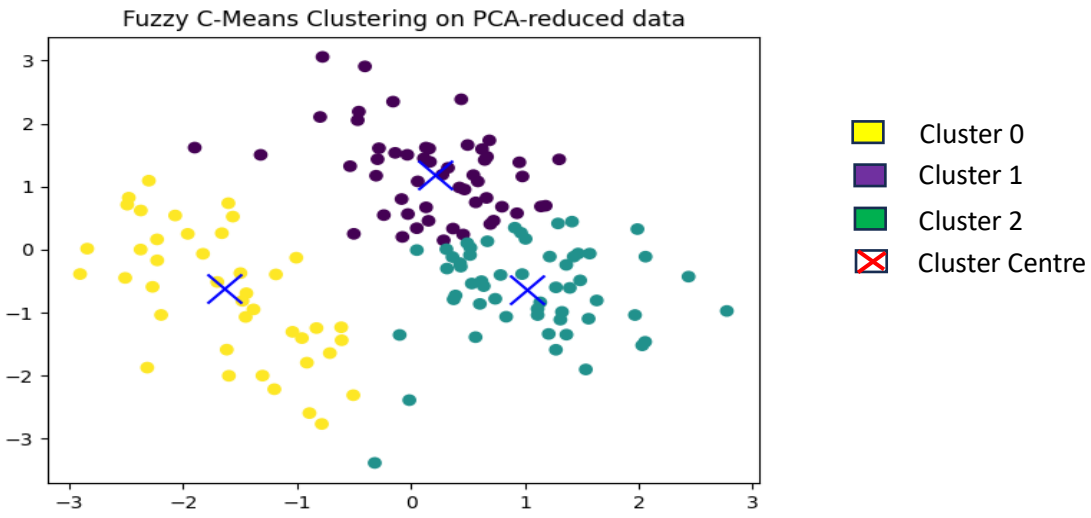

Figure_4.5: Fuzzy C-means Clustering on PCA-reduced data for dataset B.

Correlation HeatmapVisualization for Dataset A (K-means and Fuzzy C-Means):

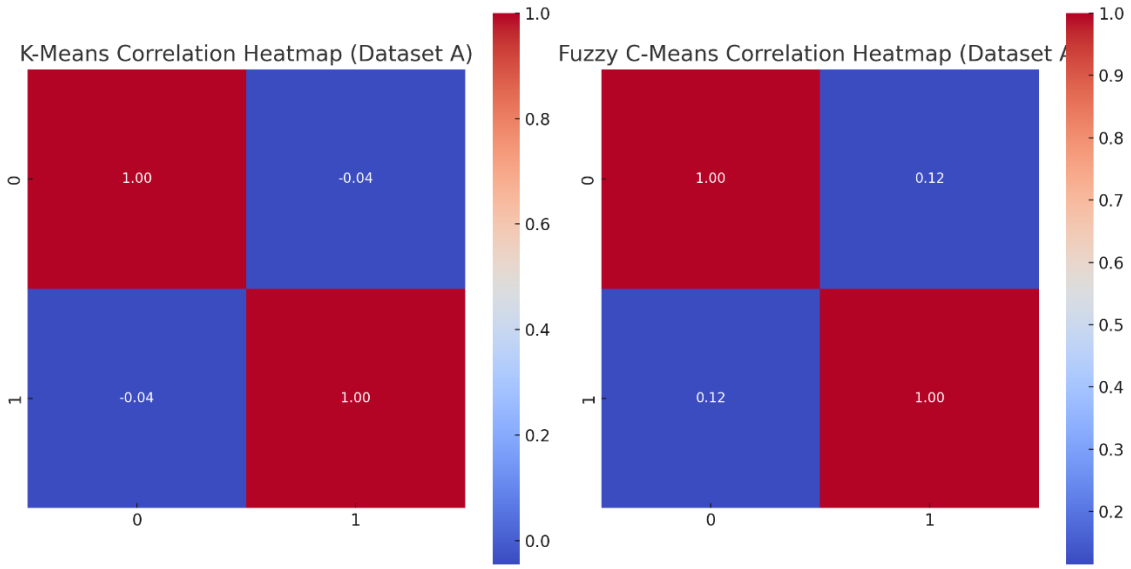

Figure_4.7: Heatmap Visualization Correlation for dataset A

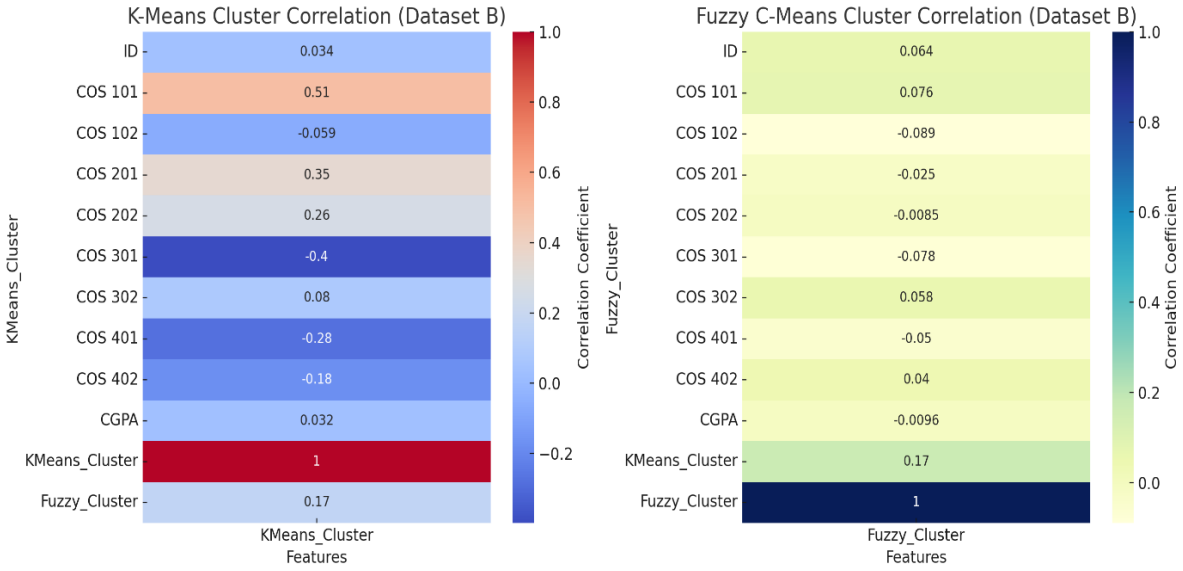
Correlation HeatmapVisualization for Dataset B (K-means and Fuzzy C-Means):

Figure_4.9: Cluster Correlation Heatmap Visualization for dataset B



Appendix F: Ethical Considerations

1. Data Anonymization: All personal identifiers were removed or anonymized to protect student privacy.
2. Algorithmic Fairness: Efforts were made to ensure unbiased preprocessing and fair representation of all student groups.

EMMANUEL LYADA – ACE21120010

Certification/ Approval

This project work was written, arranged and compiled by Emmanuel Lyada with the Registration number ACE21120010 under the supervision of Prof. John K. Alhassan and Dr. Mustapha Aminu Bagwa in partial fulfillment for the award of a master of science in cyber security.

Signed: _____ **Date**: 11th July, 2023 **.**

PROF. JOHN K. ALHASSAN

Signed: _____ **Date:** 12th July, 2023

DR. MUSTAPHA AMINU BAGWA

Dedication

I dedicate this work to God, my parents, and the Ugandan CMOs most especially UFMI and UPRS staff for their continuous support during my study.

Acknowledgments

My profound gratitude goes to the Almighty God for the wealth of His grace, mercy, guidance, strength, protection, steadfast love, and wisdom throughout the program. My sincere thanks to all parties that were involved directly and indirectly in carrying out my thesis. First, I am grateful to my supervisors, Prof. John K. Alhassan and Dr. Mustapha Aminu Bagwa, for the encouragement, guidance, and assistance that enabled me to finish my work. My deepest appreciation goes to the World Bank for sponsoring me in this course, I am grateful to you for your encouragement and support throughout our study. To my family, thank you for your support and encouragement. Finally to all my friends who contributed in diverse ways to making this project a reality, I say God bless you.

Abstract

The major job of a Collective Management Organization (CMO) is to negotiate and collect loyalty from copyright work users on the behavior of the copyright owner. The revenue received is used to fund the CMO's everyday operations, with a portion of it going to copyright holders and the rest going to the government as a value-added tax (VAT). The Higher institutions of learning are seen as the key contributors to the Copyright as an Intellectual Property (IP) since all members in the higher institutions of learning ecosystem are both authors and users of copyright works. In addition, because the creators of these copyrights demand loyalty as an economic advantage from their labor, CMOs fight tooth and nail to make these loyalties available for distribution to their members in order to gain their trust. The main objective of this study is to develop a copyright user licensing model for Collective Management Organizations in Uganda to support them mainly managing the licensing processes starting from content user data capturing to assessment till the final process of allocating a license certificate to the copyright content user, with the main critics of data security for all the information saved in the central distributed database. In this thesis, object-oriented programming (OOAD) design methodology was used to help in developing trial system or experiment in short time sequence for evaluation by end users with a purpose to detail and define system model interactively until users' requirements are met. The project worked closely with the CMO staff, and copyright works users and IP practitioner from Kenya, Malawi, Namibia and Ghana. Interviews and focus group discussions with CEOs of CMOs were applied to get qualitative feedback. Furthermore, a system prototype was demonstrated and the questionnaires distributed to get feedback on the designed system prototype. The results from the tested developed prototype comprised of interface user friendliness, ease of navigation within the design, consistency of the system in Tariff interpretation, system ease of use, time taken to perform tasks, and quick information access. The study recommends that a copyright user licensing model can be utilized to improve copyright user licensing processes in CMOs and reduce copyright infringement. Furthermore, it can be customized and used in any licensing firm or organization.

Chapter 1 : Introduction

1.1 Background to the study

One of the four intellectual property regimes that has the most influence on how higher institution of learning runs on a daily basis is copyright. Textual, visual, intangible, and tangible materials are frequently used in educational programs, and most of these items are protected by copyright law of any African country. Almost all students, teachers, and staff in higher education create and work with copyrightable and copyrighted content on a daily basis, making them both authors and users of copyright works. Copyright is inextricably linked to two of higher education's most well-known goals: educating students through teaching and developing scholarship and research that benefits humanity (Rooksby, 2016).

There is an economic advantage for every original creative copyright work, which means that the author or creator of such a work is entitled to a payment, known as royalty, as stated by the registrar of copyright and registrar general-Uganda Registration Service Bureau. (URSB). Therefore, Collective Management Organizations (CMOs) are established by owners of Copyright to protect and enforce their economic rights which are provided for in the law; copyright and neighboring Rights Act, 2006. CMOs are mainly responsible for royalty collection and distribution to ensure members benefit from the use of their works. They also carry out licensing activities, collect revenue from users, carry out public awareness, act as agents for their members, pay royalties to their members and make reciprocal arrangements with foreign management organizations (Koskinen-olsson & Lowe, 2012).

Uganda has three main Collective management organizations, (Monyatsi, 2016), which include the Uganda Federation of Movie Industry (UFMI) for audio-visual works, the Uganda Performing Rights Society (UPRS) for musical works, and the Uganda Reproduction Rights Organization (URRO) for reproduction and distribution. CMOs provide the best solution for dynamic user demands to lawfully access copyright works through agreements and licenses for rights holders that are managed directly on their behalf. Furthermore, they provide the most seamless access to content from various rights holders in the safest, simplest, quickest, inventive, practical, and cost-effective manner possible, which is only possible if the CMO is well-governed, accountable, and transparent in its operation (Stokkmo, 2015).

Collective Management Organizations deal with an increasing amount of sensitive information which include works user information as well as their business details. According to the

Registrar of Copyright & Registrar General URSB, UPRS only over 14,000 works from over 4,000 members are significantly registered and require protection, management and enforcement of their rights (UPRS, 2021). In addition, the number of copyright work user is horribly increasing with time. According to Chief Executive Officer, UPRS, over 24,000 copyright works users were currently known by 2021 August and they were scattered all over the country and every user has to be (re)accessed by the CMO licensing officers.

In this process users' data is captured by licensing officers and the information is stored in the local databases for example excel sheets. The process of reassessing and licensing of users is manually and locally handled by licensing officers, this involves manual interpretation of the tariff when allocating fees to each category of users. And due to this time consuming method and limited human resource since 2016 to 2021, the ratio of compliance costs to gross revenue expected at the end of the year was below 16%, and this was because of the limited licensing coverage scope (UPRS, 2021). In addition, users move to the CMO premises to get their license certificates after clearing payments.

Therefore, in the proposed model, tariffs for different CMOs will be automatically interpreted for the licensing officers during the licensing process, with the support of a mobile application, monitoring payments made by assessed content users, communication with the content user and payment database, geolocation of content users and generation of license certificates. This will provide a faster licensing mechanism, decentralized storage, distributed processing, and efficient lookup, capabilities, monitoring and follow up of any collective management organization licensing activity.

As collective management organizations (CMOs) move to digital systems for managing licensing data, it also exposes them to new cybersecurity risks. The storage of sensitive user data in databases and transmission of such data over networks means that strong encryption, access controls, and cybersecurity measures need to be implemented to protect against data breaches. Regular security audits, penetration testing, and staff cybersecurity training can help identify and mitigate vulnerabilities. Furthermore, disaster recovery plans, data backups, and systems redundancy need to be in place to ensure continuity of operations and rapid recovery from any cyberattacks. With proper cybersecurity controls and governance, CMOs can help securely unlock the value of copyrighted works in the digital age (Sujitparapitaya et al., 2012).

However, African CMOs face escalating cyber risks as licensing transitions to digital platforms. Recent high-profile cases illustrate the dangers: In 2021, a sophisticated cyberattack on BMI, a major US performing rights CMO, disrupted operations for months. Hackers used ransomware to encrypt systems and demand payment (BMI, 2012). A 2020 data breach at South Africa's SAMPRA CMO exposed thousands of users' personal information. Cybercriminals exploited a vulnerability in an outdated web server (Berger & Masala, 2012). In Uganda in 2018, hackers breached the Uganda Performing Right Society CMO, accessing financial records and member payment data. Weak passwords and unpatched systems enabled the attack (Serianu Limited, 2019).

These incidents demonstrate that CMOs are prime targets for cybercriminals, given the sensitive data they manage around copyrights, licensing, and user information. Threats include phishing, hacking, ransomware, and insider threats among others (Ikenwe et al., 2016). Without robust cybersecurity, CMOs risk licensing disruptions, copyright infringements, member payment issues, and loss of user trust (de Jager et al., 2015). Cybersecurity is critical for CMOs to safely transition licensing and copyright management to digital platforms. Proactive governance, controls, and risk management are essential.

This research proposes therefore a copyright user licensing model to improve licensing operations and copyright user data quality for Collective management Organizations in Uganda. This model will streamline the whole process of licensing, from reassessing of users to generation of user license certificates backed up with a mobile and web system for administration.

1.2 Statement of the problem

Collective Management Organizations (CMOs) in Uganda face challenges efficiently collecting royalties and safeguarding copyright interests due to manual, decentralized licensing processes. CMOs collect payments from diverse users like hotels, radio stations, and casinos across the country (UPRS, 2021).However, the annual revenue collection rate is currently less than 5%, limiting royalty distributions despite unprecedented membership growth (UPRS, 2022).

Licensing agents manually calculate user fees using complex tariff formulas, recording data in localized spreadsheets. With over 12,000 geographically dispersed users, assessing all for licensing is difficult using manual methods. This leads to unclear user statistics, poor data

quality, and duplication. It hinders royalty collection, causing discrimination and mistrust among members CMO (Stokkmo, 2015).

Additionally, decentralized datasets and analog processes pose cybersecurity risks. With licensing data fragmented across agents in inconsistent formats, ensuring data protection and accuracy is challenging. Lack of digital systems enables threats like data tampering and unauthorized access. As licensing transitions online, cyber-attacks could disrupt collections or breach sensitive user information (Sujitparapitaya et al., 2012).

To address these inefficiencies and cyber risks, this research proposes a digital licensing model for Ugandan CMOs. The system will automate fee calculations using centralized tariff data, improving accuracy and compliance. Digital processes will provide real-time user statistics and role-based access controls. The model will also implement cybersecurity technologies like encryption, multi-factor authentication, and malware prevention to safeguard licensing transactions and data integrity.

By modernizing and securing licensing digitally, CMOs can enhance collections and distributions, improving transparency and member relations. The model aims to balance licensing improvements with cyber protections as CMOs adopt emerging technologies. This comprehensive approach can help CMOs manage rights efficiently and safely amid rising digitalization.

1.2.1 Research Questions

i. What are the current approaches used in the process of copyright user licensing by the CMOs in Uganda?
ii. How can the copyright user licensing be improved through development of copyright content user licensing and data storage system?
iii. How can a software system help in copyright user licensing for CMOs?

1.3 Aim of the Study

The aim of this study is to develop a copyright user licensing model for Collective Management Organizations in Uganda.

1.4 Specific objective

The specific objectives for achieving the aim of this study are:

i. To analyze the current approaches used in the process of copyright user licensing by the CMOs in Uganda.

ii. To design an architecture of a copyright works licensing model for CMOs.
iii. To develop a copyright user licensing system for CMOs using PHP,MYSQL and Flutter
iv. To carryout performance evaluation of the developed system in (iii) using defect metrics

1.5 Scope of the Study

This study will focus specifically on developing a copyright licensing model for collective management organizations (CMOs) in Uganda. The scope will cover analyzing current CMO licensing limitations, investigating stakeholder perspectives, identifying enhancements, and formulating a contextualized licensing framework. While there are multiple CMOs in Uganda covering different creative sectors, the study will prioritize engaging with the national CMOs for literary works, music, visual arts, and audiovisual media, as these manage the majority of copyright licensing. The study is limited to copyright licensing and will not address other CMO activities like royalty collection and distribution.

The proposed licensing model will be developed based on the Ugandan context, but with consideration of best practices from other developing countries. The intent is not to duplicate licensing models from other nations, but to formulate tailored recommendations to improve Ugandan CMO licensing specifically.

1.6 Significance of the study

This study will generate significant original contributions as no prior research has focused specifically on formulating an enhanced copyright licensing framework for Ugandan CMOs. The licensing model developed could provide a crucial mechanism to modernize CMO licensing practices in Uganda. This has the potential to benefit copyright holders, users, and the creative industries by balancing compensation for creators with reasonable access to materials for education, research, and cultural reuse. An effective licensing model is essential for the growth of these sectors in Uganda. Additionally, incorporating cybersecurity considerations will help strengthen protections against threats that undermine rights holder interests. This research fills an important knowledge gap regarding how to improve Uganda's copyright licensing landscape to serve all stakeholders. The outcomes may be a model for CMOs in other developing countries as well.

1.7 Conceptual Framework

A diagrammatic model or depiction of the relationships between variables and how they are operationalized for research purposes is known as a conceptual framework. It is a framework of ideas, presumptions, expectations, hypotheses, and convictions that underpins and guides the investigation.

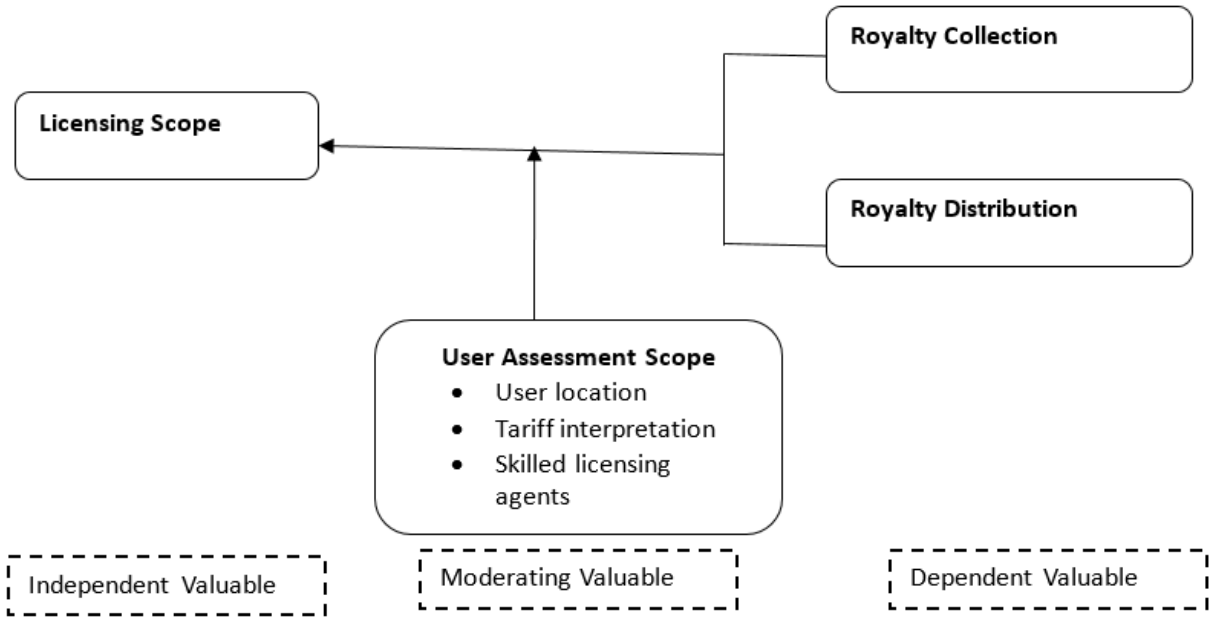

Figure 1.1 Conceptual framework showing the relationship between Valuables

The conceptual framework in Figure 1.1, demonstrates the relation between the user licensing, loyalty collection and distribution to copyright owners and how user assessment would come into play for firster achievement of copyright user licensing ecosystem.

Royalty collection and distribution are dependent on copyright user licensing scope which involves annual assessment of content user. Therefore, the higher the scope of licensing or assessment, the higher the royalty collection as well as royalty distribution to the copyright owners by the CMO.

1.8 Definition of terms

Intellectual Property Rights: The rights that people are granted over their creative works are known as intellectual property rights. Typically, they grant the inventor a time-limited, exclusive right to utilize his or her creation.

Collective Management Organization: A Collective Management Organization (CMO) is a kind of licensing organization that issues rights on behalf of numerous right holders in a single (or "blanket") license for a single payment.

License: A license grants the right to use a work from the owner to a person or organization (the "licensee"), typically in return for money. The rights attached to copyright licenses vary depending on the nature of each license and may be exclusive or nonexclusive.

Copyright: Copyright is a type of intellectual property that safeguards original works of authorship as soon as the author fixes the work in a tangible form of expression. Paintings, pictures, graphics, musical compositions, sound recordings, computer programs, novels, poems, blog entries, movies, architectural works, plays, and many more sorts of works are protected by copyright laws.

Royalty: A legally binding payment granted to an individual or business in exchange for continued use of their assets, such as copyrighted works, franchises, and natural resources, is known as a royalty. Payments made to musicians when their original songs are broadcast on radio or television, used in motion pictures, performed live at events like concerts and bars and restaurants, or heard via streaming services are an example of royalties.

Right holder: Creator of copyrighted works or person to whom these rights have been transferred.

Client: A person or organization that has mandated a collective management organization to grant licenses and collect copyright remunerations on their behalf.

1.9 Organization of the thesis

The following chapter would be Chapter 2 Literature Review, which would describe previous research on a similar system, the appropriate programming language, and methodology. Chapter 3 Methodology would discuss the methodology chosen after some research in the second chapter; this chapter would include detailed actions to be taken at each stage. It contained information on the system's specification and designs as well as a detailed description of each model in Chapter 4 Result and Discussion. Chapter 5 will include conclusion, recommendation, further research as well as contribution to knowledge.

Chapter 2 : Literature Review

2.1 Preamble

Copyright and user licensing are critical in creating the legal and ethical framework for intellectual property protection and creative work use. The copyright user licensing processes have gotten increasingly complex as content usage has increased, posing new issues for creators or content owners, as well as middlemen or CMOs. This literature review intends to provide information about current and upcoming trends in copyright works user management and licensing referencing, which will be sourced from articles, published papers, text books, and other internet sources to gain a thorough understanding of the subject. The emphasis will be on the research topics posed in the preceding chapter, and prior studies, as well as Copyright licensing-related systems, will aid in avoiding duplication of study.

2.2 Theoretical framework

The theoretical framework for copyright user licensing models is based on the concept of property rights. Copyright holders have the exclusive right to use their copyrighted works, and users have the right to access and use those works. Copyright user licensing models allow copyright holders to grant users limited rights to use their copyrighted works, while still retaining ownership of those works.

2.2.1 Enhanced License Management Model

For the online music industry, an enhanced license management model allows both online and offline purchases. The concept is made for digital rights management systems with the goal of increasing user satisfaction with DRM technology by offering a variety of ways to access and use music and, to a lesser extent, other media materials that are DRM-protected. When a customer listens to rights-protected music, the audio player initiates the license acquisition procedure. Figure 2.1 depicts the license acquisition procedure, which requires the audio player to validate the consumer's licensing status. If there is a legal license, the audio player can play the music. In the absence of a valid license, the process of obtaining one will either result in the receipt of an official license from the external DRM services center, which serves as the official license site, or the receipt of a temporary license from the local DRM services center, which functions as the local license site. Always go with the official license above any other option. As a result, the

player will communicate the consumer's private key, client information, and music identification to the external DRM services center if the user is online. If no local DRM services center is available, the player will request a temporary license from the center if one is available. To generate a temporary license, the nearby DRM services center requires a music identity and the customer's private key. When the token or coupon is downloaded from the official license site, the location of the local DRM services center is disclosed to the audio player, while the address of the external DRM services center is contained in the digital music. As a result, depending on whether the consumer is able to connect to the external DRM services center, the license acquisition operation can be performed in either the external or local DRM services center (Kwok, 2002).

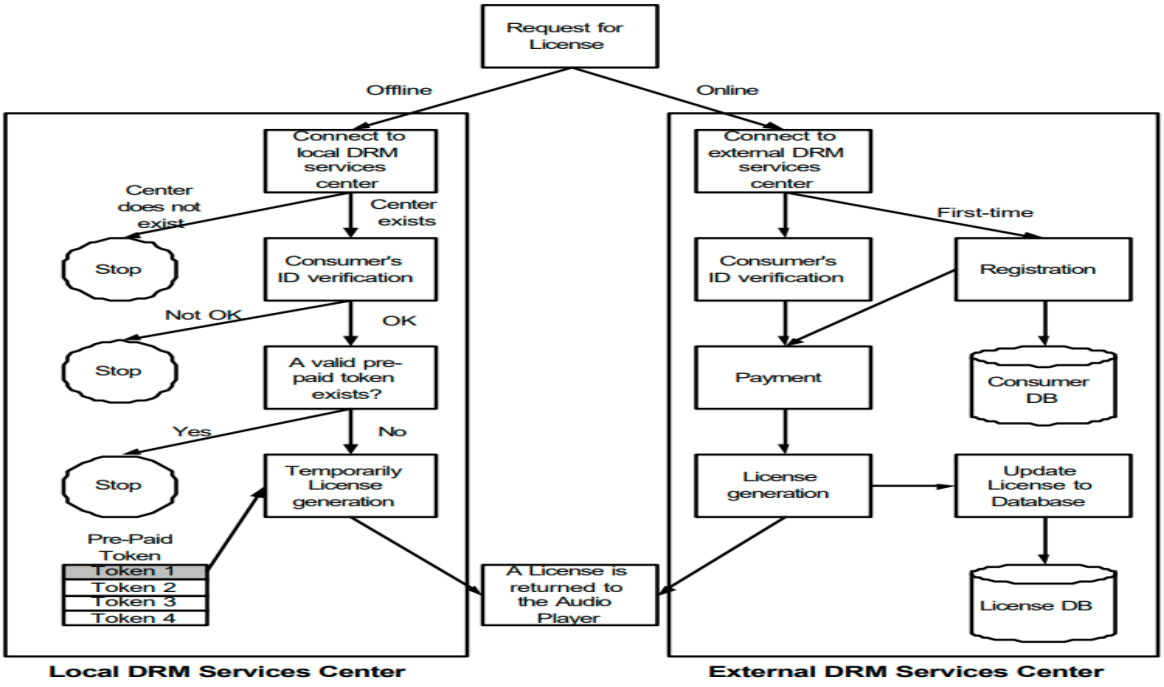

Figure 2.1 The license acquisition process in the enhanced license management model (using both local and external DRM services centers) (Kwok, 2002)

2.3 Review of Relevant Literature

2.3.1 Copyright license model and CMO

Copyright licensing refers to the permissions granted by rights holders to access and utilize creative works under specific conditions. Collective management organizations (CMOs) play a key role globally in copyright licensing by issuing licenses and collecting royalties on behalf of

rights holders (IPO, 2016). Research indicates CMOs help reduce licensing transaction costs through collective administration, but still face challenges developing optimal licensing models (Towse et al., 2008). Studies of CMOs in developing countries like Nigeria and Indonesia reveal persistent issues with licensing efficiency and rate-setting (Tabaro, 2005). Common limitations include use of statutory rates rather than market-based pricing, lack of segmentation for different user groups, and insufficient data to set fair rates (Mark, 2009). This literature demonstrates shortcomings in CMO licensing models especially in developing country contexts similar to Uganda.

2.3.2 Copyright works in higher institutions of learning

According to Rooksby (2016), copyright is the most important component of how higher institutions of learning operates on a daily basis. Copyright protects a huge percentage, if not the majority, of the textual, visual, intangible, and tactile resources utilized in education. Every day, most people in higher institutions of learning, including teachers, staff, and students, generate and use copyrighted and copyrighted works. Copyright is inextricably linked to two of higher institutions of learning's most fundamental goals: teaching and creating scholarship and research that improves humanity. All of these activities involve the use and creation of original works of art that have been recorded on a tangible medium.

In addition, Bynum (2012), argues that, copyright is an author's inherent right to control their creative outputs, and copyright protection promotes the creation and dissemination of educational resources in the higher institutions of learning. This point of view is reflected, for example, in scholarly standards regarding credit-giving and plagiarism-prohibition, which encapsulate the sense of natural justice shared by many people. The availability of learning resources, in particular, in African educational systems, is relevant to both utilitarian and natural rights-based conceptions of copyright.

Bolik (2018) argued that, it would be ideal if all institutions revised their rules in a way that adheres to openness and the common good principles. However, where updates are made, they may be contentious and represent the competing goals and limits those schools and institutions face. In the absence of significant reform, open educators would be wise to design and deliver extensive training in these areas. Participants must understand their situation before and after receiving support. In OER projects, the consistency of institutional control and the agency of producers, who are allowed to assign their preferred license in ways that the institution may not

favor, must be balanced. In addition open educators who run OER stipend programs should consider drafting a memorandum of understanding with their Office of General Counsel that explicitly indicates who owns the copyright to works produced as a result of running such programs (Bolick, 2018).

According to Ravas (2016), Campus copyright conversations should be sparked by open education initiatives. A clear policy statement or memorandum of understanding might aid in defining the standards at a particular organization. Currently, librarians provide some training on these areas. Establishing legal ownership is critical, but so is ethics, especially when students are active in the knowledge generation process. The fundamental decision about who will own OER and whose guidelines will govern how this frequently collaborative effort can be shared relates to core openness ideals. Rather than relying on broad assumptions about academic tradition, the field must decide how to balance these issues and incorporate our beliefs into these legal agreements.

According to Cox, et al (2020), faculty understanding of OER is growing. As a result, learner-centered pedagogies such as OER-enabled pedagogy, which encourages faculty and student creation of publicly licensed materials, are gaining traction. This is especially true in digital learning environments, which have become important as a result of the corona virus sickness in 2019. Closer investigation of copyright ownership restrictions is required to establish any potential legal repercussions for open education as a whole, which is dependent on the sharing ethos.

2.3.3 Copyright works user governance and management in CMOs

CMOs get personal information from Members and Users, as well as occasionally confidential or delicate commercial information. A CMO should handle such sensitive or personal data with care, constantly adhering to the laws that govern the protection of personal information, trade secrets, and privacy. It is best practice to make sure that personal data is only maintained and used for the purposes for which it was initially obtained and that consent is sought for any additional processing of data, even though the applicable data privacy laws vary from nation to country. When requesting a Member's agreement to transfer personal data about that Member overseas, CMO should inform the Member that some foreign nations may have laxer or nonexistent data protection rules (WIPO, 2018).

In addition, ARIPO argued that any organization's operation and success depend on effective governance. It is crucial for CMOs to follow good governance standards in the collective management industry because doing so would help them win over their stakeholders and users. As CMOs deal with royalties that belong to a sizable number of right holders, it is especially crucial to maintain openness and accountability. For CMOs to get more members, sign contracts with users, and expand their mandates, their behavior is crucial (Monyatsi, 2016).

The ICT Officer at UPRS argued in the 2022 annual report that CMOs in Uganda, primarily UPRS and UFMI, use Open Data Kit (ODK) to capture user data by licensing agents during the assessment process, and that this data is partially stored by the system at the end of the day. As a result, the user data is exported to an excel sheet that is maintained locally by the CMO. The user data storage or database does not currently exist because data is kept and analyzed in excel sheets. In additions, there is only a CMO members and their works database, which is still under development, and most of them are aiming for member registration through a portal, while CMOs are aiming to customize the international database for members' works. among these database include WIPO Connect database, WID- works information database, CAPASSO- (Composers, Authors and Publishers Association) Database for online mechanical rights royalty distribution , IPI- interested party information (UPRS, 2022).

2.3.4 Royalty collection and licensing

In Uganda, copyright law grants CMOs authority to license and enforce rights, but research has identified limitations in local licensing models. Tabara (2005) found an overreliance on arbitrary statutory royalty rates, exacerbated by a lack of rate-setting data. And also highlighted a lack of differentiated pricing for various uses and users (Tabaro, 2005). Kuchena (2020) noted cybersecurity and transparency concerns. These studies expose need to improve the sophistication of Ugandan CMO licensing to balance stakeholder interests (Kuchena, 2020).

Royalty collection and licensing is the process of collecting payments from users for the use of copyrighted works. It is a complex process that involves multiple parties, including copyright holders, users, and royalty collection organizations. Copyright holders are the owners of copyrighted works, such as music, movies, and books. They have the exclusive right to authorize others to use their copyrighted works. Users are the people who use copyrighted works. They may be individuals, businesses, or organizations.

According to Registrar of Copyright and Registrar General URSB, every original creative copyright work has a financial benefit, which means that the author or creator of the work is entitled to compensation for its use, also known as a royalty. The main job of CMOs is to collect and distribute royalties so that members can profit from the use of their creations (Ariana, 2016). CMOs are permitted to represent the copyright and neighboring rights interests of their members under the provisions of the Copyright and Neighboring Rights Act of 2006. Because of this agency relationship, CMOs like UPRS are obligated to efficiently collect royalties and safeguard the copyright interests of their members. A single artist may be owed royalties by a variety of users, including hotels, radio stations, television stations, and casinos, but it can be challenging to collect these payments (UPRS, 2021).

According UPRS (2022), the rate loyalty collection and user response to payment of loyalty is still so alarming due to lack of innovation to speed up the rate of assessment. As only users from one region that is central region is being assessed and less respond to the call hence not making payments

Table 2.1. User Assessment , Collection and Response (UPRS, 2022)

Years	2019	2020	2021	2022
Total No. of Users	2000+	2384	6110	12,000+
Collections/Revenue	710,710,801	257,956,537	330,094,739	247,000,000
Paying Clients	712	168	95	139

The rate of licenses granted to users according to Table 2.1 were only 712 in 2019 out of 2000 and above users, 168 out of 2384 users in 2020 ,95 out of 6110 users in 2021 and finally 139 out of 12000 and above content users in 2022.

CMOs in Uganda are aiming at subcontracting a private licensing company as a new mechanism known as Agency Licensing which is considered the future of royalty collection improvement and licensing market expansion.

2.3.5 Copyright User Tariffing System

Copyright user tariffing system is a system that lets copyright holders to charge users royalties for using their copyrighted works. Governments or business organizations are normally in

charge of implementing Copyright user tariffing system. Copyright user tariffing system works by levying a fee for the usage of copyrighted material. The tariff is usually determined by the type of copyrighted material, the number of users, and the length of use. The tariff is paid by the user to a CMO, which subsequently distributes the royalties to the copyright holders. Copyright user tariffing system have several advantages over other systems of royalties collection, such as voluntary licensing. Copyright user tariffing system are more efficient since they do not necessitate individual licensing negotiations with each user. Copyright user tariffing system is also more equitable because they require all users to pay the same rate for the use of copyrighted material.

According to FICSOR (2002), Owners of rights grant permission to collective management organizations to monitor how their works are used, negotiate with potential users, grant licenses in exchange for reasonable compensation based on a tariff system and under reasonable conditions, collect that compensation, and then distribute it to the rights holders.

According to (Sterling, 2004), the rights of each area should be valued based on how much it is exploited, and licensing fees should be computed in accordance with the destination country's tariffs, either based on the volume of users or the intensity of use. Each national collecting society may set a global cost for multi-repertoire and/or multi-territory licensing. Insofar as the applicable national percentage tariff is applied in proportion to the amount of such revenue or the number of users that can be assigned to each territory, these tariffs take elements such as the advertising revenue stream generated or the intensity of use in each country into account.

According to UPRS (2022), the tariff system provides equations for assigning payments to various sorts of copyrighted information consumers. Normally, the tariff Because of fluctuating economic conditions and the expanding licensing structure, this is done every five years, albeit the most recent review was in 2016, and the next one isn't due until 2021. The existing digital licensing tariff is insufficient to generate the desperately needed funds. The broadcasters' tariff does not currently include a sound recording tariff. Since the existing tariff does not cover the smallest music users, proposals for a fourth class have long been floated. This has had an impact on our business operations and has encouraged noncompliance. Some of User Tariffs in Uganda include:-

i Beaches and similar open-air premises

ii Live music performances ,libraries, hotels, guest houses, and similar multi-roomed establishments

iii Amusement arcades, parks, and fairgrounds

iv Roadhouses, takeaways, and similar premises bars, gardens, pubs, and similar premises,

v Restaurants, cafes, coffee shops, and similar premises

vi Shops, stores, showrooms, offices, banks, gyms, and similar premises and many others.

2.3.6 Challenges faced by CMOs

As CMOs conduct their operation, they deal with an increasing amount of sensitive information which include works owner information, works user information as well as the works information. According to the Registrar of Copyright and Registrar General URSB, UPRS only over 14,000 works from over 4,000 members are significantly registered and require protection, management and enforcement of their rights (UPRS, 2021). The number of copyright work user is horribly increasing with time, according to Chief Executive Officer , UPRS , over 24,000 copyright works users were currently known by 2021 August and they are scattered all over the country and every user has to be (re)accessed by the CMOs making the licensing process tedious. The process of reassessing and licensing of users is manually and locally handled by licensing officers, this involves manual interpretation of the tariff when allocating fees to each category of users. And due to this time consuming method and limited human resource since 2016 to 2021 , the ratio of compliance costs to gross revenue expected at the end of the year is below 16% because of the limited licensing coverage scope (UPRS, 2021).

With the help of international organizations like World Intellectual Property Organization (WIPO) and International Confederation of Societies of Authors and Composers (CISAC) platforms and databases of musical works are freely accessed to register , access and manage the copyright works on behave of their members (CISAC, 2022) .

The glittering market scope on the cyber space has attracted CMOs to promote the usage of digital / online music consumption channels and support right owners, especially the upcoming creators to host their own online music channels as a way to promote the works of their members, which is an open space for downloading and live streaming of the works (Watson, 2015). This requires an intelligent data security model with a different protection set of practices that limit access to those who have permission to access it for efficiency in copyright

management and royalty allocation among multiple copyright holders in cyberspace which is a virgin environment for piracy (Kapsoulis et al., 2020)

In addition, ARIPO in 2016 also summed up the key main challenges faced by CMO in African as follows:

i. Users' unwillingness to pay royalties
ii. Lack of awareness of copyright laws by users and general public
iii. Piracy
iv. Inadequate manpower
v. Inadequate resources
vi. Licensing educational institutions for RROs
vii. Collaboration and partnership with other stakeholders within and outside the country
viii. Collaboration with the copyright office
ix. Increasing awareness of collective management among and support by right holders
x. Availability of technologies that can be used by CMOs (Monyatsi, 2016) .

In general, the majority of the issues facing CMOs in Uganda today revolve around royalty collection, miss management, and data management, all of which are typically caused by low assessment scope, unskilled or inexperienced licensing agents who struggle to understand CMO tariffs and a lack of resources for them to use on a daily basis. These issues could be avoided if the proper mechanism of a faster assessing, reporting, and data management system was in place.

2.3.7 Distributed Database

A distributed database has two or more files spread across multiple locations, whether or not they are connected by the same network. Many database nodes are involved, and the database is physically divided into different locations for processing and storage. A centralized distributed database management system (DDBMS) conceptually integrates the data in order to handle it as if it were all held in one location. The DDBMS synchronizes all the data on a regular basis, ensuring that any changes and deletions made in one area are automatically reflected in the data stored elsewhere. A centralized database, on the other hand, consists of a single database file that is distributed across multiple networks (Lindsay, 2018)**.**

In addition, Dinesh Thakur argued that there are both homogeneous and heterogeneous distributed databases. In a homogeneous distributed database system, all physical sites use the

same operating system, database software, and underlying hardware. Because they appear to the user as a single system, homogeneous distributed database systems can be significantly easier to build and administer. For a distributed database system to be considered homogeneous, the data structures at each location must be the same or compatible. Furthermore, the database software used at each location must be compatible or identical. In a heterogeneous distributed database, the hardware, operating systems, or database applications at each location may differ. Although different sites may use different technologies and schemas, a difference in schema may make query and transaction processing difficult. Different nodes may have dissimilar hardware, software, and data structures, or they may be located in incompatible locations. Users may be able to access data stored elsewhere, but they cannot upload or modify it. Because heterogeneous distributed databases are frequently difficult to use, many businesses believe they are economically unviable (Dinesh, 2023).

2.3.6.1 Types of distributed databases

There are two types of distributed databases that is Homogenous and Heterogeneous, Figure 2.2 describes the types of distributed databases according to Rajiv (2021).

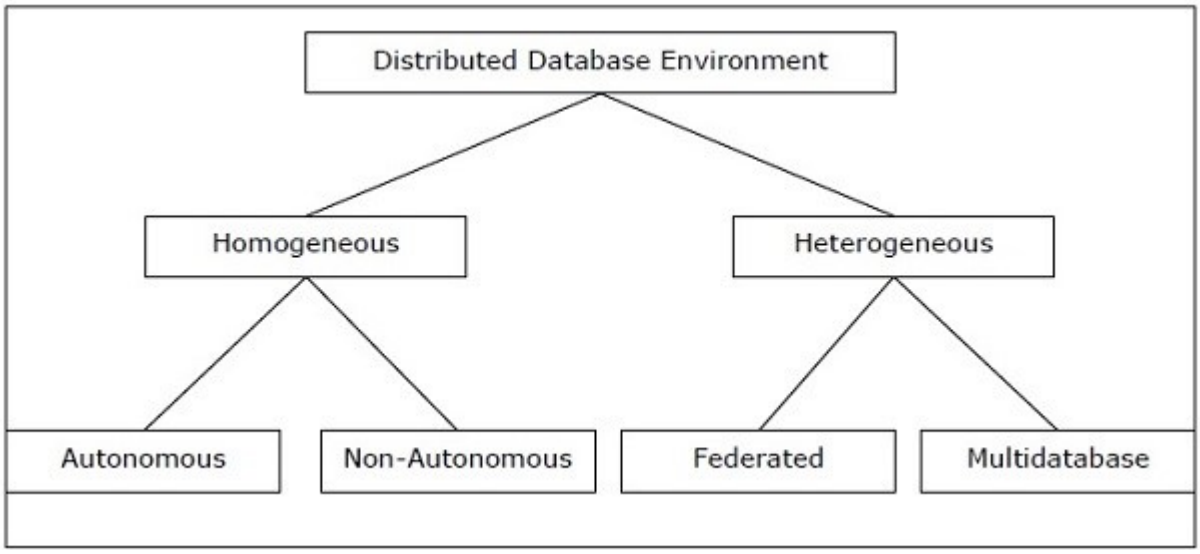

Figure 2.2 Distributed databases Classification (Rajiv, 2021)

Rajiv urged in 2021 that each category of distributed databases, homogeneous and heterogeneous distributed databases, have two types of distributed databases and they are defined as follows:

For homogeneous distributed database are:

i. Autonomous; Each database is independent that functions on its own. They are integrated by a controlling application and use message passing to share data updates.
ii. Non-autonomous; Data is distributed across the homogeneous nodes and a central or master DBMS co-ordinates data updates across the sites.

And for Heterogeneous Distributed Databases are:

i. **Federated**: The heterogeneous database systems are independent in nature and integrated together so that they function as a single database system.
ii. **Un-federated**: The database systems employ a central coordinating model through which the databases are accessed (Rajiv, 2021).

2.3.6.2 Examples of distributed databases

Among the many distributed databases available are Apache Ignite, Apache Cassandra, Apache HBase, Couchbase Server, Amazon SimpleDB, Clusterpoint, and FoundationDB. And they are described as follows:-

i. **Apache Ignite**: This can store and process large data sets across node clusters. Ignite was released as open source by GridGain Systems in 2014, and it was later accepted into the Apache Incubator program. In Apache Ignite, RAM is the database's default processing and storage tier.
ii. **Apache Cassandra**: This used a Query Language called Cassandra Query Language, and it supports clusters that span multiple locations (CQL). Cassandra replication strategies can also be tailored
iii. **Apache HBase**: It provides a fault-tolerant mechanism for storing massive amounts of sparse data. It also has Bloom filters for each column, in-memory operation, and compression. Despite the fact that Apache Phoenix provides a SQL layer for HBase, HBase is not intended to replace SQL databases.
iv. **Couchbase Server**: a NoSQL software package, is best suited for an interactive application that serves multiple concurrent users by creating, storing, and retrieving, aggregating, altering, and presenting data. Couchbase Server provides scalable key value and JSON document access to support these various application needs.

v. **Amazon SimpleDB** is used as a web service alongside Amazon S3 and Amazon Elastic Compute Cloud. Developers can use Amazon SimpleDB to request and store data with minimal database maintenance and administrative effort.

vi. **Clusterpoint**: This eliminates the complexity, scalability issues, and performance constraints of relational database architectures. To manage data in the XLM or JSON formats, open APIs are used. Because Clusterpoint is a schema-free document database, it does not suffer from the scalability or performance issues that other relational database architectures do.

vii. **FoundationDB**: It is a multimodel database built around a core database that exposes an ordered key valued store with each transaction. These transactions, which support ACID characteristics, can read and write keys stored on any machine in the cluster. Other characteristics can be seen in layers around this core (Lindsay, 2018).

2.3.8 Emergence of Database Management System

A database management system can be used to arrange, save, and retrieve data from a computer (DBMS). It is a way of communicating with a computer's "stored memory." In the early days of computers, input, output, and data storage all used punch cards. Punch cards provide a speedy way to enter and retrieve data. In 1890, Herman Hollerith is thought to have transformed weaving loom punch cards into the memory of a mechanical tabulating machine. Databases were created later. Databases, often known as DBs, have been crucial to the recent development of computers. The early 1950s saw the creation of the earliest computer programs, which were almost entirely concerned with coding languages and APIs. Data (names, phone numbers) were regarded as the byproducts of processing information at the time because computers were essentially just big calculators. When business people began using computers for practical purposes at a time when they were only beginning to be made available on a commercial basis, the residual data gained significance (Keith, 2021) .

In addition, Crieg described urged that, the system software used to create and administer databases is referred to as a database management system (DBMS). End users can create, protect, read, update, and remove data in a database with the help of a DBMS. The DBMS, which is the most common type of data management platform, primarily acts as an interface between databases and users or application programs, ensuring that data is consistently organized and is always accessible (Craig, 2022).

Database management systems (DBMS) serve as a conduit between users and databases. The user asks the DBMS to handle a variety of database operations (insert, delete, update, and retrieve). The DBMS components carry out these desired database operations and provide users with the required data. The various components of DBMS are shown below: -

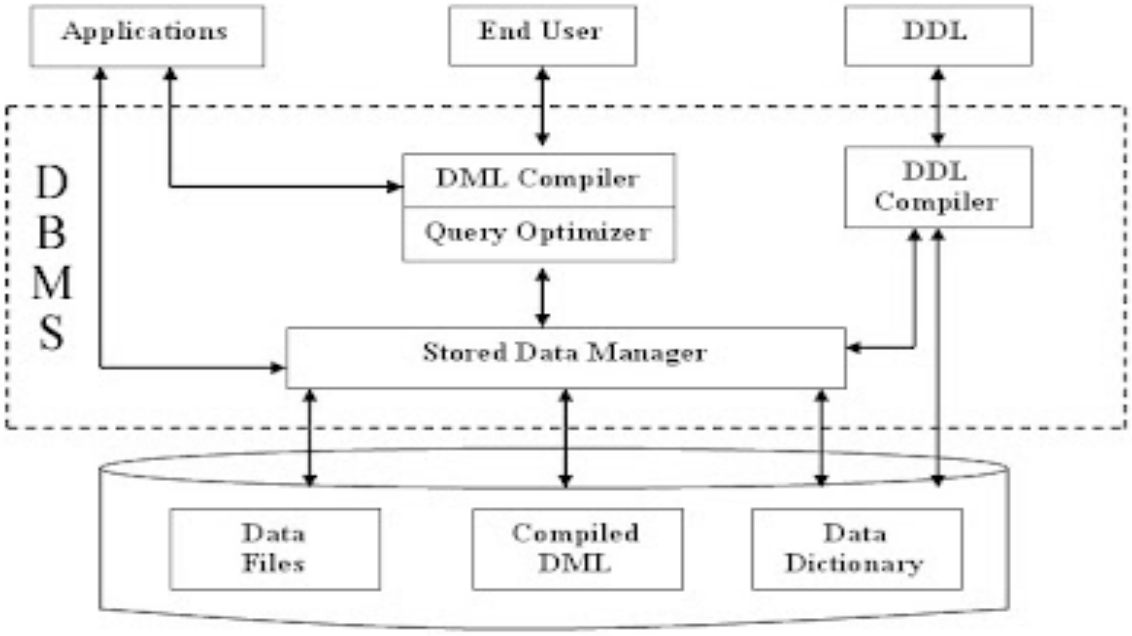

Figure 2.3 Structure of DBMS (Sumit, 2021)

i. **DDL Compiler** - Schema definitions given in the DDL are processed by the Data Description Language compiler. It includes metadata data such as file names, data items, file storage information, mapping details, limitations, etc.

ii. **DML Compiler and Query optimizer** - The DML compiler receives the DML commands from the application program and compiles them into object code for database access. These commands include insert, update, delete, and retrieve. The query optimizer then sends the object code to the data manager after optimizing it for the best query execution.

iii. **Data Manager** - The Data Manager, sometimes referred to as Database Control System, is the main piece of software that makes up the DBMS. Transform operations in user queries coming from application programs or from a combination of a DML compiler and a query optimizer, known as a query processor, from the user's logical view to a

physical file system; controls how DBMS information stored on disk is accessed; it also manages main memory handling buffers; and it imposes restrictions to preserve the consistency and integrity of the data. Additionally, it synchronizes the concurrent processes carried out by users; it also manages backup and recovery procedures.

iv. **Data Dictionary** - A database's data dictionary serves as a repository for data descriptions. Data is described therein, including the names of the tables, the properties of each table, their names and lengths, and the number of rows in each table; relationships between database transactions and the data objects they reference, which are important for identifying which transactions are impacted by changes to certain data definitions; restrictions on the data, such as the allowed range of values; information in-depth on the physical database design, including storage layout, access paths, files, and record sizes; The definition of access authorization is the description of database users' roles, obligations, and access permissions; use metrics like query and transaction frequency; The correctness, efficiency, and data integrity are truly controlled by a data dictionary.

v. **Data Files** - It contains the data portion of the database.

vi. **Compiled DML** - The DML complier converts the high level Queries into low level file access commands known as compiled DML (Sumit, 2021).

2.3.9 Types of Databases Management System

There are several types of database management systems and among the common database management systems are discussed as follows:

2.3.8.1 Hierarchical databases

In a hierarchical database management system (hierarchical DBMS) Model, data is stored in a parent-children relationship node. Records in a hierarchical database provide information about their groups of parent/child connections in addition to real data. The organization of data is done in a tree-like structure in a hierarchical database model. The information is kept in the form of a set of fields, each of which holds a single value. Links into a parent-child relationship are used to connect the records. Each child record in a hierarchical database model has a single parent. A parent may have several kids. One must search through each tree until the record is located in order to extract the data for a field. A parent-child connection node in a tree contains data.

Applications with excellent performance and availability are typically built using hierarchical databases in the banking and telecommunications sectors. In the early 1960s, IBM created the hierarchical database system structure. At the same time, the parent-child one-to-many relationship makes the hierarchical structure straightforward but rigid. Famous examples of hierarchical databases are Windows Registry and the IBM Information Management System (IMS) (Arjun, 2023).

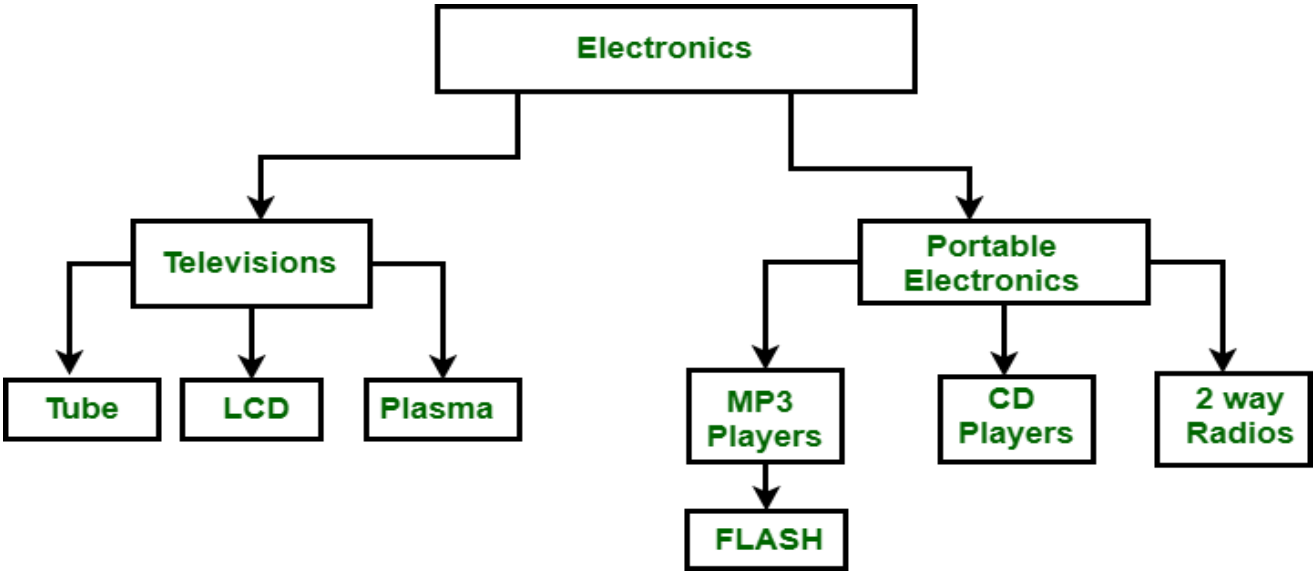

Figure 2.4 Structure of a Hierarchical Data Model (itskawal2000, 2022)

The hierarchy model includes the following: The topmost node is referred to as the root node, and it contains nodes that are connected via branches. They can be referred to as root segments if multiple nodes are present at the top level. Each node has exactly one parent, and one parent may have numerous children.

2.3.8.2 Network databases

In order to establish a connection between entities, network database management systems (Network DBMSs) require a network structure. Large digital computers are primarily used for network databases. Although network databases are hierarchical, they differ from traditional databases in that a network node can have relationships with several entities in addition to just one parent. A network database resembles a web of connected records or a cobweb more than anything else (Arjun, 2023).

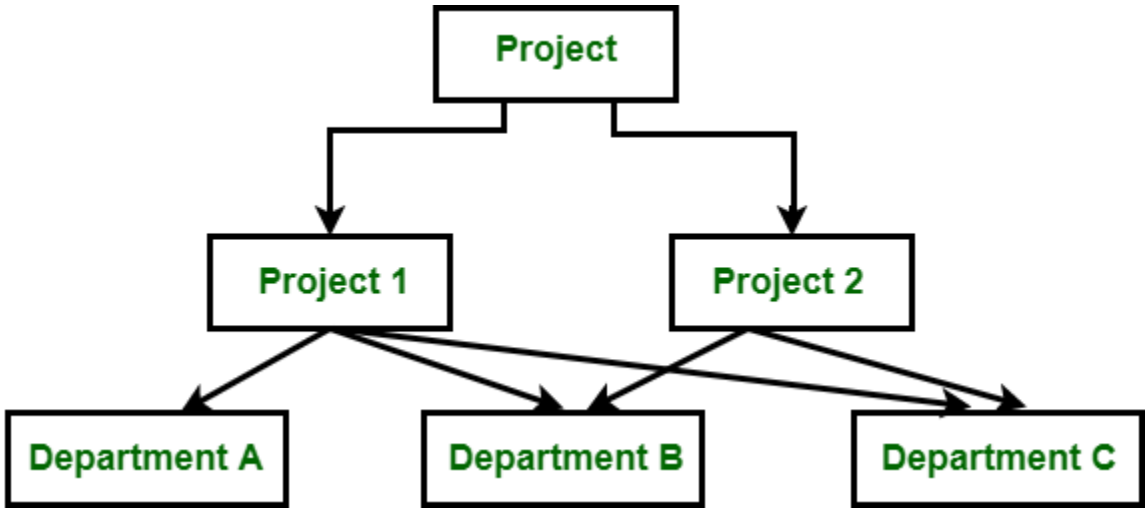

Figure 2.5 Structure of a Network Data Model (itskawal2000, 2022)

A network database model's main benefit is that it permits many-to-many relationships, which increases flexibility and accessibility. Faster data access, search, and navigation are the end results. The network data model approval process is comparable to that of a hierarchical data model. Many-to-many relationships are used to organize the data in network databases. Network database structures were developed by Charles Bachman. The Integrated Data Store (IDS), IDMS (Integrated Database Management System), Raima Database Manager, TurboIMAGE, and Univac DMS-1100 are a few well-known network databases.

2.3.8.3 Relational databases

In a relational database management system, the data relationship is relational and is maintained in tabular form as columns and rows (RDBMS). A database row represents a record, and a table column represents an attribute. Each field in a table represents a data value. Structured Query Language (SQL) is used to perform RDBMS queries, which also allows for record searching and updating. In a relational database, each table has a key field that uniquely identifies each Row. Using these key fields, one table of data can be linked to another. Relational databases are the most popular and widely used. Well-known DDBMS include Oracle, SQL Server, MySQL, SQLite, and IBM DB2 (Arjun, 2023).

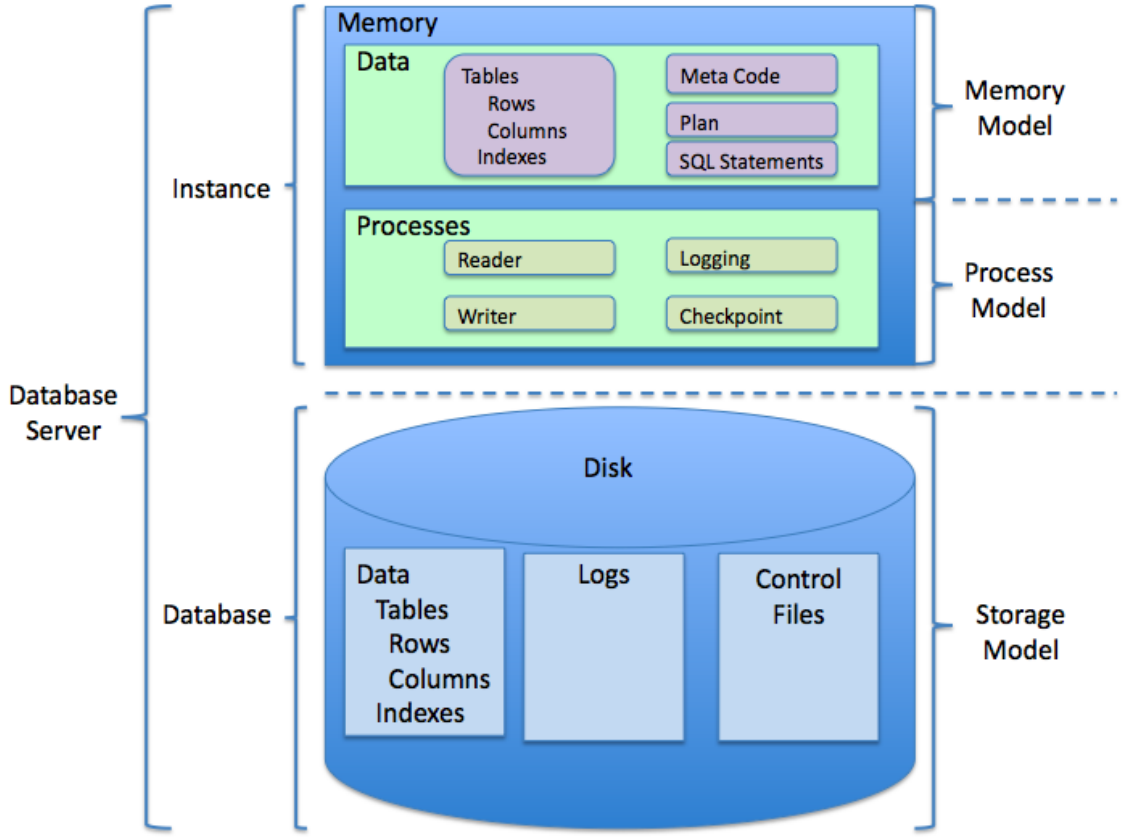

Figure 2.6. Structure of a Rational Database (Arjun, 2023)

Relational databases can be used with little or no training, and their entries can be changed without requiring the entire body to be specified. Furthermore, rational databases are endowed with the following characteristics: Values are Atomic; each row is independent; and column values are the same. The columns are unremarkable; the row sequence is insignificant; and each column has a common name (Arjun, 2023).

The most popular relational database management system are discussed as below according to (Mahesh, 2022) .

i. Oracle: A database schema in Oracle Database is a grouping of logical data structures or schema objects. A database schema that bears the same name as the user name belongs to a database user. Schema objects are human-made structures that make reference to database data directly. The most significant schema objects supported by the database are tables and indexes, while there are numerous more types as well. One

kind of database object is a schema object. Roles and profiles are two examples of database items that don't live in schemas.

ii. MySQL: The most widely used open source, free database in the world is MySQL. As part of the 2009 acquisition of Sun Microsystems, MySQL was acquired by Oracle. The SQL in "MySQL" stands for "Structured Query Language" in MySQL. The most popular standard language for accessing databases is SQL. Depending on your programming environment, you might enter SQL directly (for instance, to generate reports), incorporate SQL statements into other languages' code, or use a language-specific API that obscures the SQL syntax.

iii. SQL Server: One of the most well-known databases in the world is the SQL Server database, created by Microsoft. SQL Server, which was first introduced in 1989 and was developed in C and C++, is now extensively utilized by big businesses. Azure SQL Server, a version of SQL Server, is also a component of Microsoft's Azure cloud. The most recent edition of SQL Server is 2019.

iv. PostgreSQL: With many capabilities that safely store and scale the most complex data workloads, PostgreSQL is a robust, open-source object-relational database system that uses and extends the SQL language. PostgreSQL has been actively developed on the core platform for more than 30 years and has its roots in the University of California, Berkeley's POSTGRES project from 1986. PostgreSQL's most recent release, version 11.4, was made available on June 20, 2019. The PostgreSQL Global Development Group manages PostgreSQL, which is developed in the C programming language.

v. IBM DB2: For your transactional and warehousing operations, the relational database IBM Db2 offers advanced data management and analytics features. This operational database is supported on Linux, UNIX, and Windows operating systems and is created to give high performance, actionable insights, data availability, and dependability.

vi. Microsoft Access: This is one of the top 10 databases for storing local data is still MS Access. Access is typically not used in centralized or distant storage. It is employed for regional little databases.

vii. SQLite: An SQL database engine that is compact, quick, self-contained, highly reliable, and fully featured is implemented by the C-language library known as SQLite. The most popular database engine worldwide is SQLite. All smartphones and the majority

of laptops come pre-installed with SQLite, which is also packaged with a plethora of other frequently used programs. The developers promise to maintain the stability, cross-platform compatibility, and backward compatibility of the SQLite file format until at least the year 2050. SQLite database files are frequently used as long-term data storage formats and as containers to move rich content between computers. Almost 1 trillion SQLite databases are currently in use.

viii. MariaDB: One of the most widely used database servers worldwide is MariaDB Server. It was created by MySQL's original creators and promises to remain open source. Google, Wikipedia, and WordPress.com are notable users. Applications ranging from websites to banking use MariaDB to transform data into structured information. It is an improved drop-in substitute for MySQL. Because MariaDB is quick, scalable, and reliable, and because it has a large ecosystem of storage engines, plugins, and other tools, it is particularly adaptable for a wide range of use cases.

ix. Informix: SQL, NoSQL/JSON, time series, and spatial data may all be seamlessly integrated with IBM Informix®, a quick and adaptable database. Informix is a preferred option for a variety of situations, from business data warehouses to custom application development, thanks to its adaptability and simplicity of use. Informix is a good choice for embedded data-management solutions due to its compact footprint and self-managing features.

x. Azure SQL: Based on the most recent stable version of Microsoft SQL Server Database Engine, Azure SQL Database is a general-purpose relational database-as-a-service (DBaaS). You can create data-driven applications and websites with SQL Database, a high-performance, dependable, and secure cloud database, without having to worry about managing infrastructure.

2.3.8.4 Object-oriented databases

It necessitates more than simply storing objects from programming languages. C++ and Java semantics are being expanded in object DBMS. It supports native languages and provides full database development capabilities. It provides database access to object-oriented programming languages. The object-oriented programming method is analogous to the development of applications and databases in a consistent data model and language environment. Applications use more natural data modeling, require less code, and have simpler code bases. Object

developers can create entire database applications with a little extra effort. Object-oriented database derivation is made up of the integrity of object-oriented programming languages and consistent systems. Object-oriented databases' power comes from the cyclical treatment of both persistent data (found in databases) and transient data (found in running programs) (Arjun, 2023).

Object Oriented Data Model = Combination of Object Oriented Programming + Relational database model

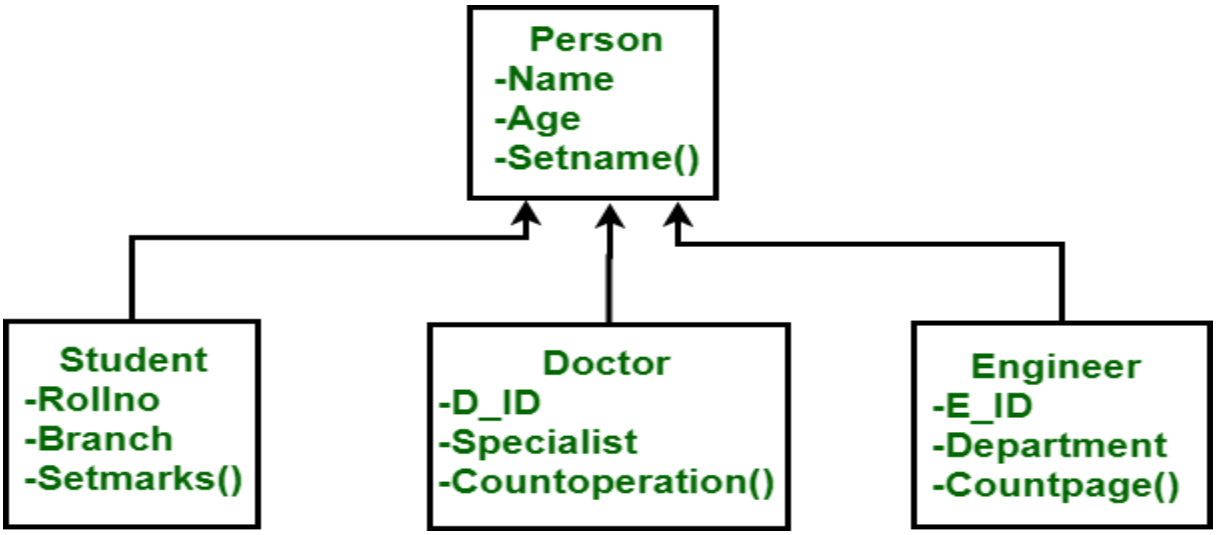

Figure 2.7. Structure of an Object Oriented Data Model (Arjun, 2023)

Objects: An object is an abstraction of a real-world thing, or we could call it a class instance. Data abstraction is made possible by objects, which combine data and code into a single entity and shield the user from the implementation specifics. Examples are the student, doctor, and engineer symbols in Figure 6.

Attribute: An attribute describes an object's characteristics. For instance, in the Student class, the object STUDENT's attributes are Roll no, Branch, and Setmarks().

Methods: The behavior of an object is represented by a method. In essence, it mimics what happens in reality. Consider this: Identifying a STUDENT'S marks in Figure 6 as Setmarks ().

Class: A class is a group of related objects that share properties and methods for behavior as well as common structure. A class instance is an object. For instance: Figure 6: Human, student, doctor, and engineer (itskawal2000, 2022).

In addition, Arjun complemented that early in the 1980s, object-oriented database management systems (OODBMs) were developed. Several OODBMs were made to work with OOP languages including Python, Ruby, C++, Delphi, and Ruby on Rails. TORNADO, Gemstone, ObjectStore, GBase, VBase, InterSystems Cache, Versant Object Database, ODABA, ZODB, and Poet. JADE, and Informix are a few examples of well-known OODBMs (Arjun, 2023).

2.3.8.5 NoSQL databases

According to Craig(2022), SQL is not the primary data access language used by NoSQL databases. Common NoSQL databases include graph databases, network databases, object databases, and document databases. Because NoSQL databases lack preset schemas, they are the ideal choice for development environments that change quickly. NoSQL enables developers to make adjustments instantly without impacting running programs. Document databases, graph databases, key-value stores, and wide-column stores are the four categories of NoSQL databases. Each NoSQL variety has distinct characteristics since they each employ a different kind of data model. The NoSQL database management systems categories are described as follows:-

i. **Document databases**

Semi-structured data and descriptions of that data are stored in document databases, typically in JavaScript Object Notation (JSON). They are helpful for changeable schema needs, which are typical of content management systems and mobile apps. Couchbase and MongoDB are two well-known document databases.

ii. **Key-value stores**

A straightforward data model that pairs a distinct key with an associated value is the foundation of key-value storage. Key-value stores can be used to create extremely scalable and effective systems because of their simplicity, such as those for maintaining shopping cart information for online shoppers or session management and caching in web applications. Redis and Memcached are two prominent key-value databases as examples.

iii. **Graph databases**

NoSQL databases that use graph structures for semantic queries are called graph databases. Nodes, edges, and attributes represent the data in storage. A Node in a graph database represents an entity or instance, like a client, a person, or a vehicle. A node in a relational database system is comparable to a record. In a graph database, an edge represents the connection between two

nodes. Properties are extra details that are added to the nodes. Famous graph databases include Neo4j, Azure Cosmos DB, SAP HANA, Sparks, Oracle Spatial and Graph, OrientDB, ArrangoDB, and MarkLogic. Several RDBMS, notably Oracle and SQL Server 2017 and subsequent versions, support the graph database structure as well.

In addition, Ian, Jim, & Emil (2014) elaborated that graph database management systems are requently designed with transactional integrity and operational availability in mind, and they are typically optimized for operational performance. When researching graph database technology, two aspects of these databases should be taken into account and these include:-

i. **The underlying storage**: Some graph databases make use of native graph storage, which is optimized and created for the purpose of storing and maintaining graphs. The usage of native graph storage is not common among graph database solutions. Some people serialize the graph data and store it in a relational database, an object-oriented database, or another type of multipurpose data store.
ii. **The processing engine**: In accordance with some definitions, a graph database must use adjacency without indexes, in which case linked nodes in the database really "point" to one another. Here, we adopt a slightly broader perspective: any database that, when viewed from the user's perspective, behaves like a graph database (that is, exposes a graph data model through CRUD operations) is considered to be a graph database. We do, however, acknowledge that index-free adjacency offers meaningful performance benefits, and as a result, we refer to graph databases that make use of index-free adjacency as native graph processing. (Ian et al., 2014):

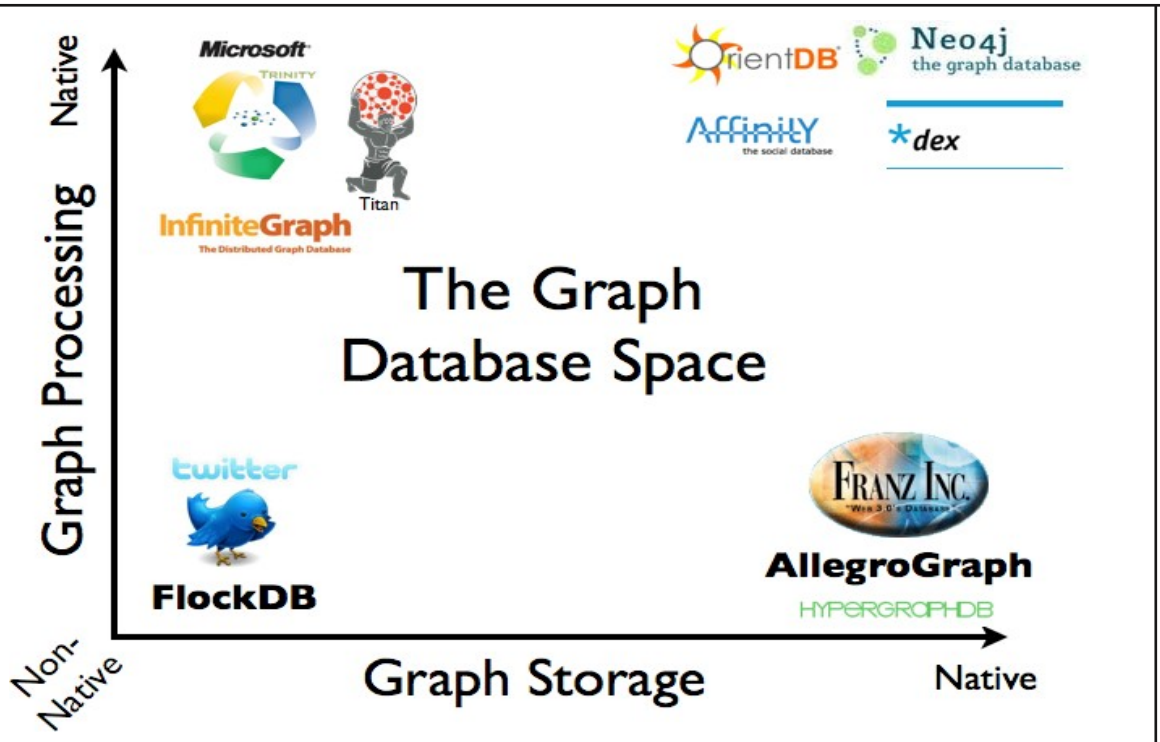

Figure 2.8. An overview of the graph database space (Ian et al., 2014)

iv. **Wide-column stores**

The conventional tables, columns, and rows of relational database systems are used by wide-column stores, although column names and formatting might vary from row to row within a single table. Moreover, each column is kept separate on the disk. A wide-column store is preferable to conventional row-orientated storage for performing data queries by columns, such as in recommendation engines, catalogs, fraud detection, and event logging. A couple of examples of wide-column stores include Cassandra and HBase.

2.3.10 Uses of Database Management Systems

In 2022, Craig argued that one benefit of employing a DBMS is that it permits concurrent access to and use of the same data by users and application programmers while maintaining data integrity. Instead of creating fresh iterations of the same data stored in new files for every new application, data is better safeguarded and maintained when it can be shared using a database management system (DBMS). Many users can access the central data store that the DBMS offers in a regulated manner. Data abstraction and independence, data security, a locking mechanism for concurrent access, an effective handler to balance the needs of multiple applications using the same data, the ability to quickly recover from crashes and errors, strong data integrity

capabilities, logging and auditing of activity, straightforward access using a standard API, and uniform administration procedures for data are all provided by central data storage and management within the DBMS. In addition he added that Database administrators (DBAs) can impose a logical, hierarchical arrangement on the data using DBMS. Because DBMSs are designed for such tasks, they provide economies of scale for processing massive amounts of data. Moreover, a DBMS can offer numerous views of a same database design. A view specifies the data that the user sees and the format in which they view it. Between the conceptual schema, which establishes the logical structure of the database, and the physical schema, which details the files, indexes, and other physical processes the database employs, the database management system (DBMS) offers a level of abstraction. When business requirements change, users can adapt systems considerably more quickly and easily with a DBMS. A DBA can expand the database's data categories without affecting the current system (Craig, 2022).

In 2015, Kahl also expressed the database management systems as being vital because they manage Redundancy: Having a centralized database and centralized data control by the DBA prevents unnecessary data duplication in a database system. They also eliminates the need for additional processing time due to the volume of data. Improve Data Sharing: DBMS allows users to share data among a variety of application programs. Data Integrity, because of centralized data control, the administrator can specify data integrity requirements for the database. Because the DBA has complete control over operational data, he or she can ensure that only authorized users have access to the database. In addition they support Data independence, faster data access, lower application development and maintenance costs, and data consistency are all advantages (Kahl, 2015).

2.3.11 Suitable Programming Language

A variety of programming languages can be used to construct an internet application or a mobile application. After reviewing the available programming languages, two well-known programming languages for web application development are picked. PHP and ASP.net can be picked from the various languages to do research into which programming language is most suited for use. According to (Varun, 2022) the assertion, PHP for web apps and Flutter Dart for hybrid mobile applications have the following advantages over ASP.NET and other programming languages:-

i. PHP and dart are easier to use than ASP.NET and other programing languages.
ii. PHP and flutter dart are more user and platform friendly ASP.NET and other programing languages.
iii. Unlike ASP.net and MSSQL, which users must pay for, PHP and flutter dart has a connection to MySQL, which is both free.
iv. PHP has many developers from around the world because it is an open source programming where anyone can help and improve it, whereas ASP.net is limited to the skills of Microsoft developers only.
v. PHP and flutter is free, whereas ASP.NET is not.
vi. PHP and flutter is more secure.

2.3.12 Study on why Designers Often Use Php Over Asp.Net

PHP is frequently chosen by web designers over ASP.net. Because PHP is a fairly straightforward language and is always free, this is the case. Although it is possible to create ASP.NET applications without investing in developer tools, each one has its own restrictions. In comparison to PHP, ASP.net web design blogs and articles are less common. The differences between the PHP and ASP.net are listed in a table of comparison as follow (Varun, 2022).

Table 2.2 Comparison between PHP and ASP.NET

	PHP	**ASP.NET**
Cost	Free (Open source)	Licensing cost
Support and Resources	Developers contribute to the open source make Improvement and updates. Takes shorter time to provide feedbacks (developers from around the world)	Relies on developers at Microsoft which are limited by the numbers of developers takes longer time to feedback to users
Editors and tools	Tools/editor independent	Microsoft Visual Studio
Platform	Independent – can run on any platform Linux, Unix, Mac OSX, Windows	Run only on Windows Platform
Usability	User interface of Linux is getting better	User interface in Microsoft Server is degrading

Table 2.3.Popularity of programming languages used in websites

Site	Programming language
Google.com	PHP and MYSQL
Facebook.com	PHP and MYSQL
Youtube.com	PHP and MYSQL
Yahoo.com	PHP and MYSQL
Wikipedia.com	PHP and MYSQL
Amazon.com	PHP and MYSQL
Msn.com (owned by Microsoft)	ASP.NET
Live.com (owned by Microsoft)	ASP.NET

2.3.13 Outcome of Study on Suitable Programming Language

According to the aforementioned points, PHP connects to the MySQL database, both of which are free, whereas ASP.net uses MSSQL and requires license payments. Because PHP is more established than ASP.NET, it has access to more tutorials and code examples. The fact that PHP is an open-source programming language, where developers from all over the world may make improvements and offer assistance when users need it, is the most crucial of all. The fact that PHP is platform neutral is another crucial feature. While ASP.NET is only supported by Windows, PHP is compatible with many operating systems, including Mac OS X, Linux, and Windows. It is advantageous to use PHP to construct web applications since it may run on any platform. Also, compared to ASP.NET, there are more websites using PHP and MySQL, making it simpler to find materials or tutorials for PHP programming.

In summary, the majority of well-known websites use MySQL and PHP for their databases. The only websites that use ASP.NET are those that are owned by Microsoft, such msn.com and live.com. Many people utilize programming languages like PHP with MYSQL.

2.4 Related Works

2.4.1 QuickBooks (Client Server System)

QuickBooks is an accounting software that helps businesses to keep finances organized and accurate initiated and made by Intuit.

In addition, Renuka Rana complimented that QuickBooks contains the basic accounting, reporting and invoicing, as well as offering add-on services allowing you to handle things like inventory tracking, payroll, sales and credit card processing. The software is updated every year, with added features (Rana, 2015). The QuickBooks architecture is designed to be scalable and reliable, and it can be used to support a wide range of business needs.

The QuickBooks architecture is based on a three-tier architecture, which consists of the following layers:

i. Presentation layer: The presentation layer is responsible for displaying data to users and collecting input from users. The presentation layer is typically implemented using a web browser.
ii. Application layer: The application layer is responsible for processing data and performing business logic. The application layer is typically implemented using a Java EE application server.
iii. Data layer: The data layer is responsible for storing data. The data layer is typically implemented using a relational database.

The QuickBooks architecture is designed to be scalable and reliable. The presentation layer can be scaled horizontally by adding more web servers. The application layer can be scaled horizontally by adding more application servers. The data layer can be scaled vertically by adding more disk space and memory to the database server.

The QuickBooks architecture is also designed to be secure. The presentation layer uses HTTPS to encrypt data in transit. The application layer uses Java EE security features to authenticate users and protect data. The data layer uses a relational database with strong security features.

This is a CMO financial management system for (books of accounts) in Uganda. It is a client-server system with several users' accessibility capacities.

Information is easy to find and manage because it can be accessed and managed in one location for all tasks and information linked to customer management. All of your customers and the precise amount they owe are shown on one screen. When you click on a customer's name, all of

your interactions with them are immediately visible. You don't need to switch to a different screen to get the necessary client contact information because it is all present in this view, including the customer's phone number, fax number, and payment terms. Contacting a customer who is past due is simple (Intuit Inc, 2023).

2.4.2 Unified Communication and Collaboration System – UCCS

The technology and software known as unified communications and collaboration (UCC) integrates workplace communication with real-time and asynchronous cooperative capabilities.

This unified messaging and collaboration system is used by the Ugandan government to improve coordination and cooperation among all branches of the government. It makes use of standard email and gives users access to teamwork software. The CMO uses the same system to streamline daily operations and provide for both members and music consumers (UPRS, 2022).

In 2022, Katherine Finnell, argued that to increase connection and productivity, unified communications and collaboration unifies the numerous techniques utilized in individual unified communications and collaboration services and makes them accessible through a single interface.

In addition, Email, voicemail, calendars, scheduling tools, video conferencing, instant messaging (IM), desktop sharing, and VoIP are all included in UCC. Furthermore, features might include unified messaging, which enables you to access all of your messages from a single spot, and presence tracking, which allows you to determine whether a contact is available or busy (Katherine, 2022).

2.4.3 Open Data Kit System (ODK)

In Uganda perspective, CMOs Field license officers use open data kit application system to collect all necessary licensing details from commercial users of music and at the end of the day exported to an excel sheet.

A collection of open-source tools called the Open Data Kit (ODK) enables businesses to gather and manage their data. The ODK system architecture is designed to be scalable and reliable. ODK Collect can be used on a variety of mobile devices, including smartphones, tablets, and laptops. ODK Aggregate can be deployed on a variety of servers, including Amazon Web Services, Microsoft Azure, and Google Cloud Platform. ODK Central is a cloud-based application that can be accessed from anywhere with an internet connection.

The ODK system architecture is also designed to be secure. ODK Collect uses HTTPS to encrypt data in transit. ODK Aggregate and ODK Central use industry-standard security features to protect data from unauthorized access.

The ODK system architecture is a flexible and scalable platform that can be used to collect data in a variety of settings. ODK is a valuable tool for organizations that are working to improve the lives of people in developing regions. A more detailed explanation of ODK's architecture and operation was made and published, followed by a timeline of its development and application (Loola Bokonda et al., 2020).

However, take note that ODK now provides an architecture that divides the tools into three sets:

i. Desktop Clients: These are the programs that you install on a desktop or laptop. The ODK graphical tool for creating forms is called ODK Build. ODK XLSForm is designed to create forms that are more complicated than Build's and convert Excel files into Xform formats that are compatible with ODK tools. On ODK servers, forms can be imported and exported using ODK Briefcase.

ii. Mobile Client: This is ODK Collect, which only works with Android phones and tablets and enables the use of forms made using ODK Build to collect data. Two servers are recommended by ODK. The storage, processing, and presentation of gathered data are all possible with ODK Aggregate. An alternative server called ODK Central offers modern technologies like REST API.

ODK was developed using Java, JavaScript and Python as the programming languages (Patrick et al., 2020) and uses randomization and initialization vector generation algorithm . Initialization vector generation algorithm file encryption. Each file is encrypted using a unique initialization vector. As a result, the order of data to be encrypted is consecutive and critical for effective decryption.

```
calculate md5 digest of instanceID and the AES encryption key
convert md5 digest to a seed array of 16 bytes
start a counter at 0
for each file in the record to be encrypted - including the first - do:
    calculate index as remainder of the counter modulo 16
    increment byte in seed array at index with 1
    increment counter
    use updated seedArray as initialization vector for AES encryption
```

Figure 2.9. Initialization Algorithm

ODK is free and open mobile web application to users, users are free to create several forms within the application to capture data while in the field. Data is stored both with and without internet and then synched while connected to internet.

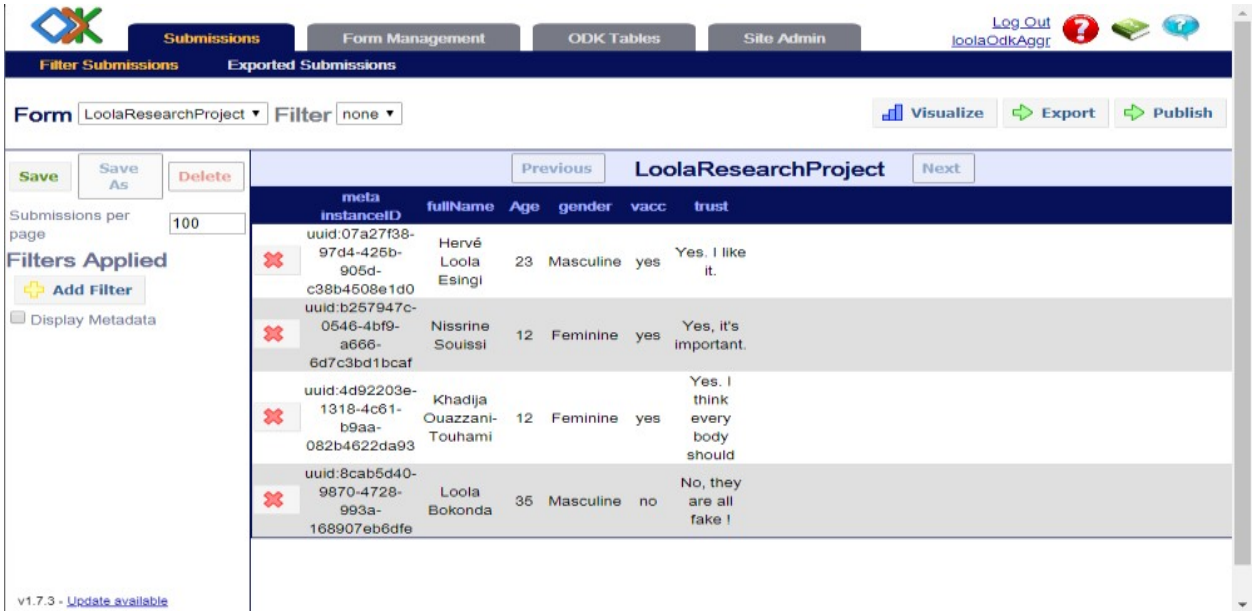

Figure 2.10. ODK aggregation font page (Patrick et al., 2020)

2.4.4 Composers, Authors and Publishers Association (CAPASSO) Portal

CAPASSO is a mechanical rights licensing agency based in Johannesburg - South Africa, which licenses, collects and distributes mechanical royalties to its members: music publishers and composers. The Composers, Authors and Publishers Association (CAPASSO) Portal architecture is composed of the following components:

i. CAPASSO API: The CAPASSO API is a RESTful API that allows developers to access CAPASSO data. The CAPASSO API is used by a variety of applications, including music streaming services, karaoke apps, and music production software.

ii. CAPASSO Database: The CAPASSO Database stores data about music compositions, including the composition's title, author, publisher, and other metadata. The CAPASSO Database is used by the CAPASSO API to provide data to developers.

iii. CAPASSO Portal: The CAPASSO Portal is a web-based application that allows users to search for music compositions, view information about compositions, and purchase licenses to use compositions. The CAPASSO Portal is used by composers, publishers, and music users.

The CAPASSO Portal architecture is designed to be scalable and reliable. The CAPASSO API is hosted on a cloud-based platform that can handle a high volume of requests. The CAPASSO Database is also hosted on a cloud-based platform that can store a large amount of data. The CAPASSO Portal is a web-based application that can be accessed from anywhere with an internet connection. The CAPASSO Portal architecture is also designed to be secure. The CAPASSO API uses HTTPS to encrypt data in transit. The CAPASSO Database uses industry-standard security features to protect data from unauthorized access. The CAPASSO Portal uses user authentication and role-based access control to protect user data.

According to (UPRS, 2022), for the purpose of collecting mechanical rights royalties online, all member works are published on the CAPASSO portal. To facilitate posting and matching of works on the primary database, it is now being synchronized with WIPO Connect.

According to (CAPASSO, 2021),any person who owns or controls the mechanical right in a musical composition and who is a composer, author, or publisher, or their successors in title, is eligible to join CAPASSO.

2.4.5 CIS-Net platform

The CIS-Net platform architecture is composed of the following components:

i. Service bus: The service bus is a central repository of services.
ii. Service registry: The service registry is a database of services.
iii. Service clients: Service clients are applications that use services.
iv. Service providers: Service providers are applications that expose services.

The CIS-Net platform architecture service bus is hosted on a cloud-based platform that can handle a high volume of requests. The service registry is also hosted on a cloud-based platform that can store a large amount of data. The service clients and service providers are distributed across multiple servers, which makes the platform more reliable.

The CIS-Net platform architecture is also designed to be secure. The service bus uses HTTPS to encrypt data in transit. The service registry uses industry-standard security features to protect data from unauthorized access. The service clients and service providers use user authentication and role-based access control to protect user data.

The CIS-Net platform architecture is a flexible and scalable platform that can be used to develop distributed applications. CIS-Net is a valuable tool for developers who want to build scalable and reliable applications.

The CIS-Net platform was developed in 1994 as a toolbox for technical standards to network with various connected databases, according to (CISAC, 2022). A node in the overall network is each database. CIS-Net is made up of three nodes: local nodes maintained by individual member societies or CMO, regional nodes maintained by regional groups of member societies, and the Works Information Database (WID) Center, a CISAC database of musical works used by many societies. The nodes are accessible through a search engine on the internet, and they allow for more extensive and effective licensing for the exploitation of the works managed by CMOs as well as quicker and more effective revenue distribution. CIS-Net, according to (Nuttall, 2011), is a distributed platform where Documentation is maintained at its point of Creation and its sub-systems consist of both Documentation databases and common tools. The CIS-Net platform has a topology that permits greater accuracy because the data is updated in real-time by the entity with full authority over it. A common protocol called CISML is utilized by all nodes (Common Information System Markup Language). Every CIS-Net sub-system can communicate with every other sub-system thanks to this XML-based language. Queries, data requests, and data packages all involve CISML communication. Due to the importance of network security, a node is set aside to manage user access and track network traffic patterns.

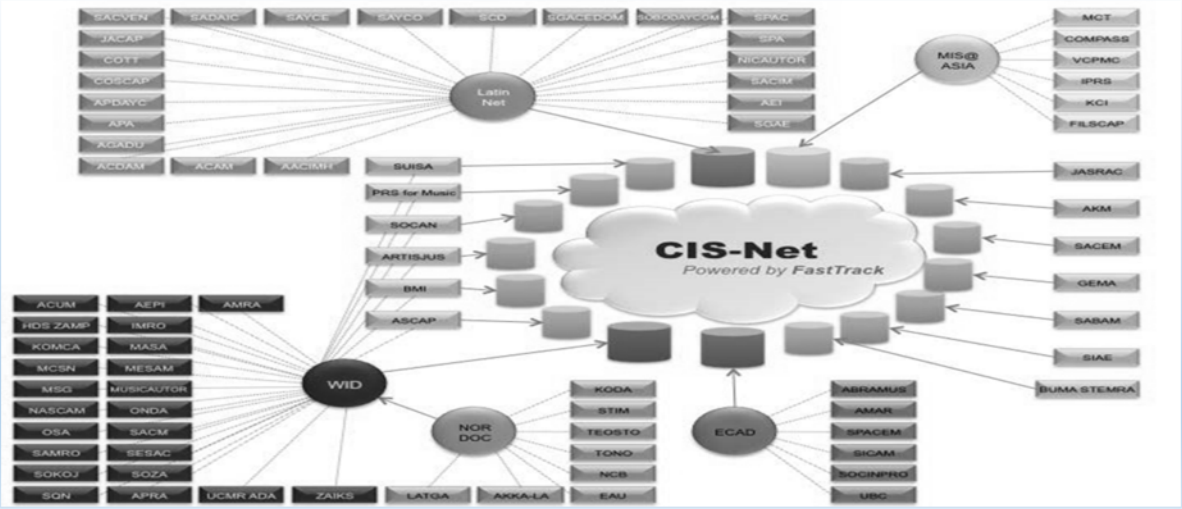

Figure 2.11. Topology of CIS-Net Powered by FastTrack (Nuttall, 2011)

2.4.6 WIPO Connect system

WIPO Connect allows Collective Management Organizations (CMOs) to manage copyright and related rights. It is a web-based platform that provides CMOs with the tools they need to collect and distribute royalties, manage their repertoire, and interact with users.

The WIPO Connect system architecture is composed of the following components:

i. Web portal: The web portal is the user interface for WIPO Connect. It allows CMOs to manage their repertoire, collect and distribute royalties, and interact with users.
ii. Data repository: The data repository stores all of the data that is used by WIPO Connect. This includes data about works, rightsholders, users, and payments.
iii. Application server: The application server is responsible for running the WIPO Connect web portal and data repository.
iv. Database server: The database server stores the data that is used by the application server.
v. Web server: The web server is responsible for serving the WIPO Connect web portal to users.
vi. Security infrastructure: The security infrastructure protects the data that is stored in WIPO Connect. This includes firewalls, intrusion detection systems, and data encryption.

The WIPO Connect system architecture is designed to be scalable and reliable. The web portal, application server, database server, and web server are all deployed on a cloud-based platform that can handle a high volume of requests. The data repository is also deployed on a cloud-based platform that can store a large amount of data.There are two models: one local and one central. It provides a practical, appropriate, and adaptable solution to help CMOs with their regular operations and collaboration with CMOs from other countries. WIPO Connect is divided into two levels of operation: WIPO Connect Shared, a fully cloud-based solution that synchronizes WIPO Connect Local implementations and exchanges data with industry data sources, and WIPO Connect Local, a day-to-day operations web application that can be installed on a local server or hosted in the cloud (WIPO, 2022).

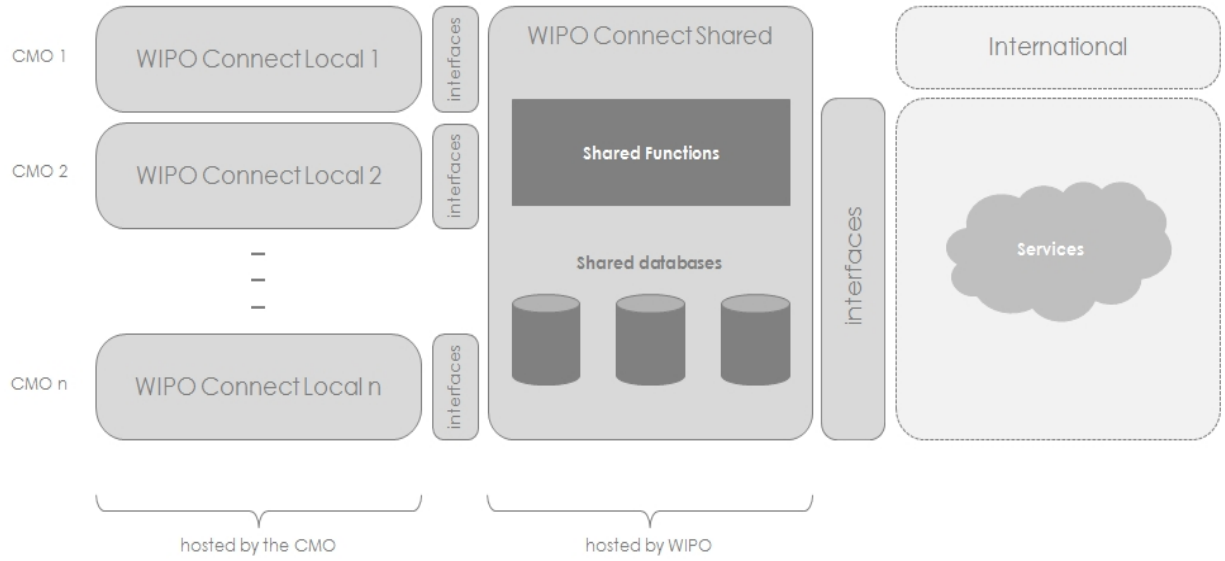

Figure 2.12. Topology of WIPO Connect system (WIPO, 2015)

WIPO Connect Local is used for registering right holders, managing documentation such as works, performances, and sound recordings, managing licensing agreements, identifying and matching works that have been used, providing usage reports, and data capture. Furthermore, it provides Distribution reports that detail the amount of royalties that will be distributed to right holders based on usage, documentation, and local parameters.

WIPO Connect Shared is used in the cloud synchronization of WIPO Connect Local implementations. Submission of documentation to industry databases and retrieving information for synchronization, Facilitating and automating industry identifier assignment, and finally, disseminating local repertoires to foreign CMOs (WIPO, 2012) .

2.5 Summary matrix for the existing systems

According to most computer-based Collective management Organization systems, the existing system is insufficient to cater for the increasing duties of CMOs, and thus with them in use, CMOs are likely to encounter some problem that will affect the smooth operation of the organization as well as their annual target objectives.

Tariffing, licensing, record keeping, and material handling are all examples of duties. The existing system may be mismanaged due to insecurity, time consuming, and the fact that the majority of content users and CMO staff do not know how to operate the existing systems, making CMO's daily activities tedious for them.

From the interview conducted shows that there is currently no user-centered CMO system in place for managing licensing processes and content user data, and all of these activities are performed manually. According to observations made and literatures read, licensing coverage is very low in relation to the increasing number of copyright content users due to difficulties in translation of the tariff by licensing officers during the user assessment process. Furthermore, there is difficulty in trucking content users (both those who have paid and those who have not paid) as well as licensing officer performance when in the field at the end of the day. Finally, most existing systems only handle one type of copyright work, namely musical works, leaving other works unaddressed and thus favoring a specific type of CMO.

After identifying the problem with the existing systems, the purpose of this research is to address it so that the new system does not suffer the same fate as the present systems. The CMO will now benefit from the new system in terms of cost savings, simplicity of work in everyday tasks, and the security of content user information contained in the system's database. It's also good at translating tariffs and determining how much loyalty the user should pay.

Table 2.4.Matrix of existing related systems

Name of the system / framework	**Features**			
	Main Objective	**Copyright Works**	**Used in Licensing Process**	**Tariff Interpretation**
1. QuickBooks	Create, update, and identify conflicts in musical rights	All	No	No
2. CIS-Net platform	Distributed platform providing Documentation databases and common tools to CMOs	All	No	No
3. WIPO Connect System	Collective management of copyright and related rights	All	No	No
4. Open Data Kit (ODK) system	Platform for capturing content user data	All	No	No
5. Unified Communication and Collaboration	Platform for communications and collaboration within	None	No	No

System (UCCS)	organization			
6. Composers, Authors and Publishers Association (CAPASSO) Portal	Portal for collecting and distributing mechanical rights royalties online	Musical	No	No
7. Proposed system	Copyrights Licensing model(Copyright User Licensing System)	All	Yes	Yes

Chapter 3 : Research Methodology

3.1 Preamble

Methodology used for developing Copyrights User Licensing is Object-oriented analysis and design (OOAD). Object-oriented analysis and design (OOAD) is a methodology used in software engineering to analyze, design, and develop complex systems. It focuses on organizing the system into objects that encapsulate data and behavior, fostering modularity, reusability, and maintainability.

During the analysis phase of OOAD, the primary goal is to understand the problem domain and gather requirements. This involves identifying the key stakeholders, understanding their needs, and capturing the functional and non-functional requirements of the system. The analysis phase aims to create a clear understanding of the problem that the software will address.

After the analysis phase, the design phase begins. In this phase, the emphasis is on transforming the requirements into a concrete design that can be implemented. The design phase involves creating a conceptual model of the system, defining the structure and relationships between objects, and specifying the interfaces and interactions between different components. It also includes making design decisions regarding architecture, data management, algorithms, and user interfaces.

OOAD utilizes several principles and concepts to guide the analysis and design process. These include abstraction, encapsulation, inheritance, and polymorphism. Abstraction involves identifying and focusing on the essential characteristics of an object while ignoring irrelevant

details. Encapsulation ensures that an object's internal state is hidden and can only be accessed through well-defined interfaces. Inheritance allows the creation of new classes based on existing ones, inheriting their properties and behavior. Polymorphism enables objects of different classes to be treated uniformly based on their shared behavior.

Throughout the OOAD process, iterative and incremental development practices are often employed. This means that the analysis and design phases are revisited and refined as new insights and requirements emerge. Iterative development promotes flexibility and adaptability by breaking down the development process into smaller, manageable cycles.

The ultimate goal of OOAD is to produce a high-quality design that fulfills the identified requirements and is capable of being implemented efficiently and effectively. By leveraging object-oriented principles and practices, OOAD enables developers to create software systems that are modular, extensible, and maintainable, ultimately resulting in more robust and scalable solutions.

3.2 Analysis of existing systems

The existing copyright works licensing and user management model in collective management organizations in Uganda is a manual process. Licensing officers of respective assess copyright content users from the field and the user data is captured in the printed forms manually designed by the CMO and at the end of the day the information captured is entered in the excel files. Other CMOs try to use ODK for collection of content user data which is then exported into an excel sheet. After assessing a user, the assessment form original copy is given to the assessed copyright content user and a photocopy remains with the licensing officer .The photocopies of the assessment forms are used for compiling copyright users after assessment process. The assessing form mainly contains the content user information, work usage information as well as the annual fees represented on the demand note. And only the licensing manager is responsible for validation of the assessment form with the help of respective licensing officers.

The annual fees are calculated manually following the hardcopies of the tariff books the licensing officers move with in the field. The tariff book contains classified copyright user groups, such as musical compositions; Hotels, Guest Houses, and Similar Multi-Room Establishments and this tariff applies to the performance or public communication of musical works and sound recordings provided by radio/television receiving sets, disc players, tape

machines, and similar devices in hotels, motels, guesthouses, banqueting suites, restaurants, and similar multi-roomed establishments with correspondent formulas for calculating the annual fees for that specific user group.

The licensing officers to be able to assess the copyright content users, they have to be capable to:-

i. Differentiate content user categories
ii. Specify the tariff which applies to a specific user group
iii. Identify copyright works in use
iv. Interpret the tariff book

Following those schemes in the tariff , each usage category is rated and assessed differently ,for example a hotel user category may have a bar , restaurant and swimming pool which are assessed differently and the assessment summery and total represented in the demand note with the total amount which is also manually calculated.

The fees are calculated following the seating capacity ranges and others square meter ranges depending on the user categories:

Table 3.1.Tariff rating for Class A of hotels, motels, guesthouses, banqueting suites, restaurants, and similar multi-roomed establishment's tariff

Particular	Annual Fees	
	Musical works	Sound Recording
For Class "A" Establishments		
Fee for every customer seating capacity up to the first 50	11,172	5,586
Fee for every additional customer seating capacity from 51 to 75	8,922	4,461
Fee for every additional customer seating capacity from 76 to 100	7,434	3,717
Fee for every additional customer seating capacity over 100	5,907	2,954

For user categories which uses seating capacity ranges having X total number of seats for musical works according to Table 10:

$$Fee\ 1 = (50 * 11{,}172) \quad (3.1)$$

Fee 2: if (X-50) is <=25 then

$$Fee\ 2 = ((x - 50) * 8{,}922) \quad (3.2)$$

Else $Fee\ 2 = (25 * 8{,}922)$

Fee 3: if (X-(50+25)) is <=100 then

$$Fee\ 3 = ((x - (50 + 25)) * 7434) \quad (3.3)$$

Else $Fee\ 3 = (25 * 7434)$

$$Fee\ 4 = ((x - (50 + 25 + 25)) * 5907) \quad (3.4)$$

$$Total\ anual\ Fee = (\text{Fee1} + \text{Fee2} + \text{Fee3} + \text{Fee4}) + (\text{Fee1} + \text{Fee2} + \text{Fee3} + \text{Fee4}) * \text{VAT}$$

Table 3.2.Tariff rating for SHOPS, STORES, SHOWROOMS, OFFICES, BANKS, GYM AND SIMILAR PREMISES tariff

Particular	Annual Fees	
	Musical works	Sound Recording
Music Audible to Members of the Public		
Fee for every unit of 10 sq. meters per annum "shop space" or part thereof up to 100 sq. meters	15,000	7,5008
Fee for every unit of 10sq meters per annum "shop space" or part thereof from 100 to 200 sq. meters.	7,500	3,7505
Fee for every unit of 20 sq. meters per annum "shop space "or part thereof above 200 sq. meters	6,750	3,375
Music Audible to Employees		
Fee per day (or part thereof) of performance for each capacity unit of 10 employees (or part thereof)	938	469

For user categories which uses square meters ranges having X Total Square meters (X m^2) for musical works according to Table 11:

If x <=100

$$Total\ Annual\ fees = \left(\left(\frac{x}{10} * 15000\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) + \left(\left(\frac{x}{10} * 15000\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) * VAT \quad (3.5)$$

If x >100 and x <=200

$$Total\ Annual\ fees = \left(\left(\frac{x}{10} * 7500\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) + \left(\left(\frac{x}{10} * 7500\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) * VAT \quad (3.6)$$

If x > 200

$$Total\ Annual\ fees = \left(\left(\frac{x}{20} * 6550\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) + \left(\left(\frac{x}{20} * 6550\right) + \left(\frac{no\ of\ employees}{10} * 938 * no\ of\ days\right)\right) * VAT \quad (3.7)$$

3.3 Limitations of the Existing System

After the analysis of the current system, the following limitations were identified.

i Tariff schemes or formulas for calculating the annual fees for different content users' categories are tedious and technical to easily be understand by a licensing agents without an intellectual property and mathematical background since annual fees are manually calculated by licensing agents.

ii During the assessment process the licensing agents or officers move place to place in search for copyright content users, therefore the current system does not locate or truck the location of the copyright content users who have been (to be) assessed and licensed.

iii The current system cannot truck licensing officers when in the field as well as their performance rate at the end of the day

iv There is no centralized database system that can safely track available copyright content users list for a specific CMO, as approximations and estimates are currently used in regards the rate of usage of copyright works. In addition the local data in the excel sheets have a lot of data redundancy and reputations.

- v The system does not have any central means of connecting between the licenses granted and loyalties collected by the CMO, as there is high chances of license duplication due to lack of clear trucking mechanism.

3.4 Problem formulation

To obtain the appropriate users' requirements, the researcher reviewed existing documents about copyright works licensing and management, Collective management Organization annual reports and publications and systems related to copyright works handling in Uganda and Africa at large to identify the different objects that are required for the system. In addition the research had physical interviews with the Chief Executive Officers of the CMOs in Uganda, staff from the copyright office National Intellectual Property Office of Uganda (Uganda Registration Service Bureau) as well as staff from CMOs. The researcher also extended further to have virtual interview with Intellectual property experts from copyright office of Kenya, BIPA Namibia, Copyright Office of Malawi as well as content users like hotels, bars, restaurants, researchers.

By looking at the current processes used while licensing copyright content users by CMOs determined what needs to be done to improve the copyright content users licensing. During the interviews, the following questions were asked to gain an understanding of where the proposed system can support, and to obtain answers on what the system should support. Open ended questions were asked to allow respondents to elaborate more of what is required by the CMOs to carry out the copyright content User licensing and questions are as followers.

Qn1; Tell us about the copyright user licensing processes used in the CMO

Qn2; By approximation, like how many copyright content users can be licensed in one day by one licensing officer?

Qn3; How do you truck there scattered copyright content users, licensing officers as well as their performance?

Qn4; How is the copyright content user data/ information managed?

Qn5; How do copyright content users get their license certificates?

3.5 Proposed solution, technique, model or framework

The new copyright user licensing system automates all copyright user licensing processes and activities related to content user licensing for CMOs and Content. Thus, the basic activities and more carried out in a manual system are performed by a computer and mobile application. The system has two actors, the CMO staff, and users of copyright works. The each CMO has a

registered system administrator who is capable of adding CMO staff and these staff depending on the department but most especially the licensing managers and licensing officers who added first to help in adding the tariff and the tariff ratings for different category of content users to the system with reference to what is in the CMO tariff books. All the user categories, tariff, and tariff ratings are stored into MYSQL database using the web version of the system.

With the help of the mobile version of the system, licensing officer or agent are capable of registering new content users, locate already registered copyright content users as well as assess the unlicensed content users for that year. The captured user data and assessment information is all saved both in SQL Lite and MYSQL databases.

After registering a content user, unique userID and one time password is granted to them for them to be able to login and access their portal. The portal will have the payment history, current annual Fees with the balance and availing a download button to download the license certificate if the annual fees are completely paid.

During the process of assessing a registered user, the licensing agent selects the user and checks the forms of works used, after assessment for each work is done and calculations are done by the system and total fees provided after assessment.

The systems have the ability of trucking the location of the licensing officers when in the field using the GPS.

3.6 Tools used in the implementation

3.4.1 Hardware tools

The hardware components of a computer system refer to the physical part that makes up the computer system. For an effective operation, the system was implemented with the following hardware components: a windows computer with at least 8GB RAM, 500GB HDD and 1.9 GHz for smooth running of the development tools as well as the virtual machine for IOS. The following hardware is required for the efficient work of the system: Any computer device which has web browser for web system, android phone of at least version 4.4 and iOS phone of at least version 8.0 for mobile application users.

3.4.2 Software tools

Computer software is a collection of computer programs and related data that provides the instructions for telling a computer what to do and how to do it. In other words, software is a set

of programs, procedures, algorithms and its documentation concerned with the operation of a data processing system. Program software performs the function of the program it implements, either by directly providing instructions to the computer hardware or by serving as input to another piece of software. For effective development of Copyright User Licensing system , the software required include , sublime text as a text editor for web, android studio as a mobile development tool , MACOS virtual machine Xcode as a testing tool for iOS version , XAMP as a local server for database development and local hosting

3.4.3 Choice of Development Environment

The choice of programming language used depends on the suitability of the language attributes to the scope and usage of the system developed. PHP is a scripting language and dart programing is used in flutter framework. They facilitate the development of a web-based program and creation of web-pages as well as hybrid mobile applications respectively. The XAMP server has some sets of scripts, logs, SQL manager and PHP code that enable communication between the MYSQL database and HTML as well as flutter. The system developed is an online system that allows multi usage. The XAMP server enables data to be shared among users online and secures the data from the various users. The cascading style sheet formats the presentation of a web page to the end-user. It creates a suitable and user friendly outlook for the user interface. These attributes informed the choice of the language used.

3.7 Approach and Technique(s) for the proposed solution

The Copyright user Licensing system allows content user data management and content user licensing process management and the key licensing process is the tariffing during assessment and license certificate generation for members with cleared annual Fees as showed in the algorithms in Figure 3.1 and 3.2.

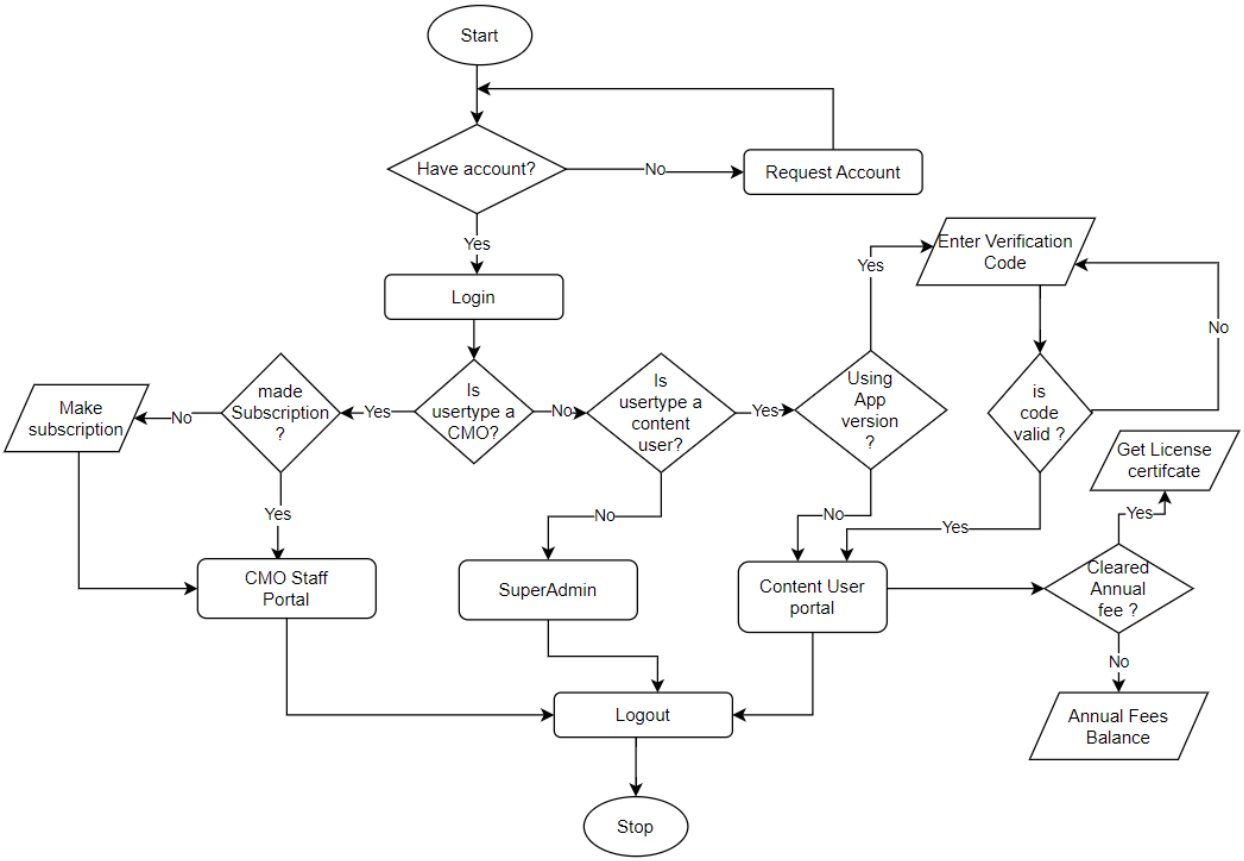

Figure 3.1. Flowchart of System Access and License access algorithm

To access the system the users login with username and password which is encrypted by MD5 digest a key factor of Initialization vector generation algorithm. If the credentials are valid, user type is checked if the user type is a CMO staff, the system checks for the CMO subscription and if it is subscribed the staff under it, can access the system. If the user type is a copyright content user, and using the web system, they directly access the portal but if using mobile app, a two factor authentication occurs, the system sends a verification code which is to be entered before accessing the portal as showed in Figure 3.2.

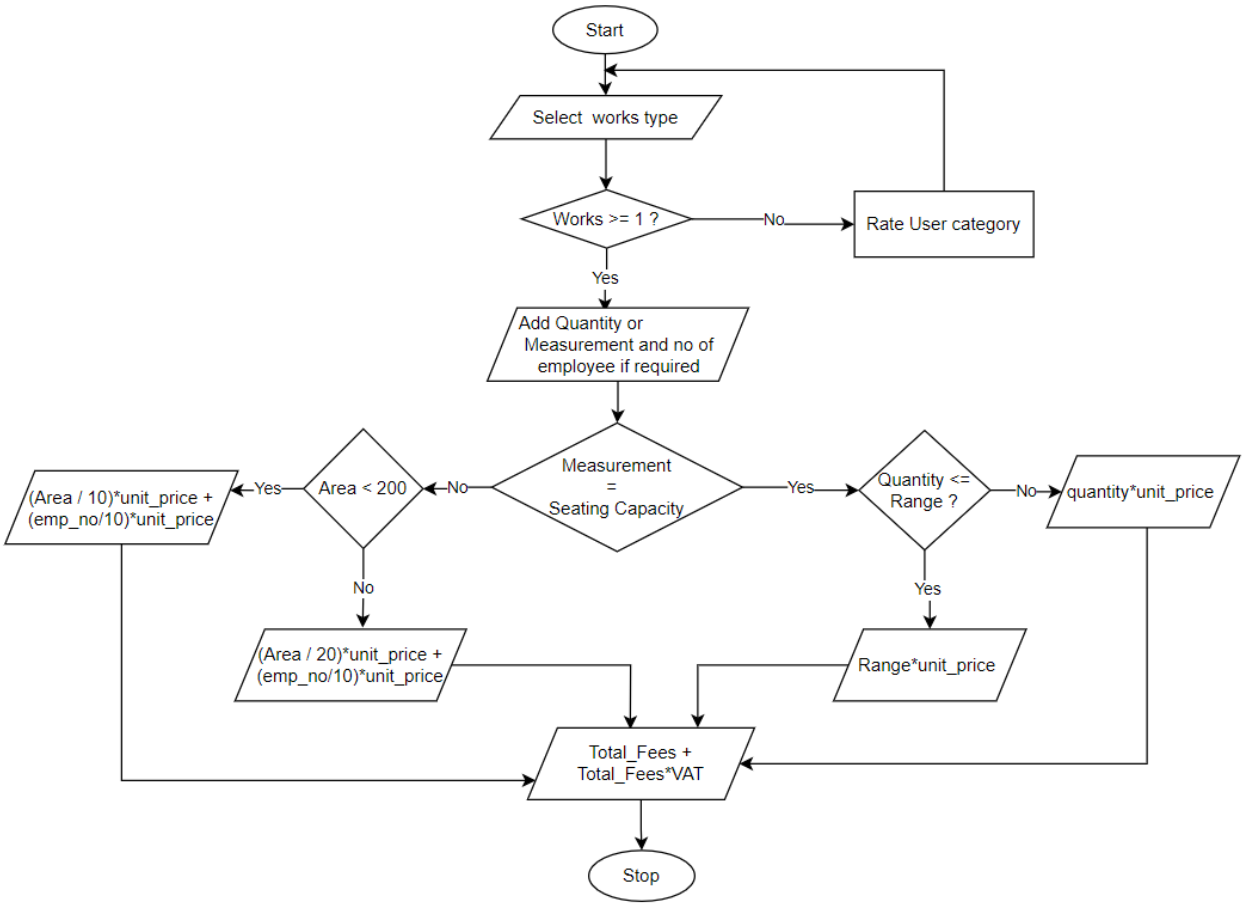

Figure 3.2. Flowchart of tariffing algorithm

The key factors in the process of tariffing during assessment are the user category, work type, quantity and their corresponding measurements. The system first checks for the rating after user selecting the user category and work type in the tariff rating table, if rating exists (work and user category), the quantity or measurements are added. The system checks for the measurement type (seating capacity or Square Meters). If square meters found, the system checks if the area>200,

$$\text{Total Annual fees} = \left(\left(\frac{area}{10} * unit\_cost\right) + \left(\frac{no\ of\ employees}{10} * unit\_cost * no\ of\ days\right)\right) + \left(\left(\frac{area}{10} * unit\_cost\right) + \left(\frac{no\ of\ employees}{10} * unit\_cost * no\ of\ days\right)\right) * VAT$$

And else if area >=200

$$\text{Total Annual fees} = \left(\left(\frac{area}{20} * unit\_cost\right) + \left(\frac{no\ of\ employees}{10} * unit\_cost * no\ of\ days\right)\right) + \left(\left(\frac{area}{20} * unit\_cost\right) + \left(\frac{no\ of\ employees}{10} * unit\_cost * no\ of\ days\right)\right) * VAT$$

and if the measurement is seating capacity quantity, and if the seating capacity quantity <= range from the database , then $Fee = (\text{quantity} * \text{unit\_cost})$ else if quantity >range then

$Fee = (\text{range} * \text{unit\_cost})$ and finally $\text{Total Annual fees} = (\text{Fee1} + \cdots + \text{Fee n}) + (\text{Fee1} + \cdots + \text{Fee n}) * VAT$ a shown in Figure 3.2.

3.8 Research Design

This design made use of object-oriented programming (OOAD) as the design methodology. A programming paradigm known as object-oriented programming (OOAD) portrays the software design process as actual objects. These objects are entities with associated methods and data fields (attributes that describe the object). In order to implement a computer application and programs, objects that are given in a code format are typically instances of classes. The state (data) and the behavior (method) are its two basic parts.

An Object-Oriented software enables:

i. Increased understanding: The software design process is simpler to grasp when combined with object-oriented analysis. The system will have objects like CMO, Content users, Tariff, and many others using, for instance, the copyright content user license and database. The system will support a variety of actions, including user and licensing officer tracking, tariff interpretation, and content user registration.

ii. Code Reusability: because the code for a certain function is contained in a single file, this function can be called up as frequently as possible for reuse. As an example. The header files and lib folder files that may be utilized by both Android and iOS. The header or title for the software "copyright user licensing system" is placed in one PHP file and is called up for reuse in all files, so that the header name or title appears on every web page.

iii. Ease of maintenance: Problem with one file do not affect the other files. Diagnosis can easily be traced to the source and corrected.

3.8.1 Use Case Diagram

The use case diagrams are usually referred to as behavior diagram used to describe the actions of all user in a system. All user describe in use case are actors and the functionality as action of system. The Use case diagram is a collection of diagram and text together that make action on goal of a process. In copyright user licensing system and database there will be three actors that can do all the activities to run the system. Super admins, CMO staff, and users of copyright works as shown in Figure 3.3.

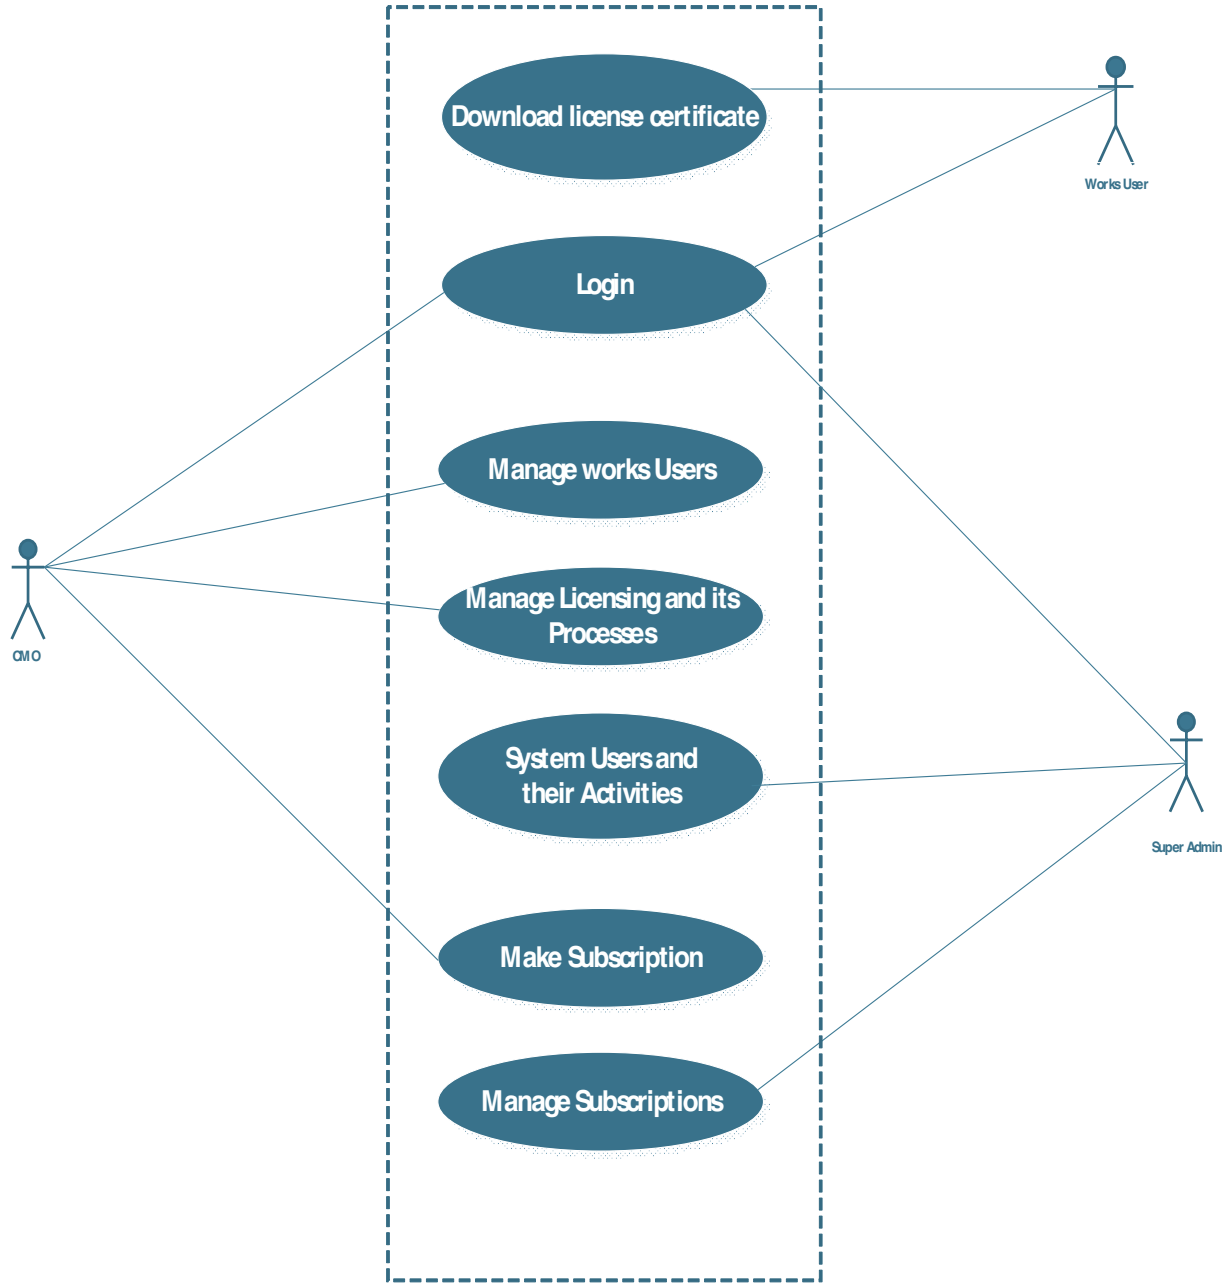

Figure 3.3 Use case diagram for the proposed system

The actors in the use case diagram, Figure 3.3, have different roles and can access the system in different ways as explained in Table 3.3.

Table 3.3.User Activity description

Users	Description

Copyright Works User	The content user will login using the user ID issued during the process of assessment and secret code auto generated by the system. On login the system will then check the userID and secret against that is stored in the database. Then a confirmation code will again be sent on his phone number to verify his or her identity. After the authentication taking place, the User will access the system. Depending on the user category, after login , the user will be able to: i. Access to access amount demanded/bill after assessment ii. Payment history for the past years i. Access downloadable license certificate after payment completion
CMO staff	The subscribed CMO system administrator must login using username and password provided during subscription, And he/she will create accounts for CMO staffs mainly the CEO, Accountant, Licensing Manager and Licensing Officers. They must also login, then after they can: i. Manage Members ii. Manage users of copyright works iii. Manage user payment iv. Manage licensing and processes v. Manage Tariffing
Super Admin	Super Admin login credentials will be simultaneous auto generated periodically by the system, and sent to the super Admin's email. And after login , The super Admin will be able to :- i. Manage CMO subscriptions ii. Manage all system users iii. Manage all activities performed within the system

The workflow of the Copyright User Licensing model is described by the activity diagram, which highlights the locations where decision-making is supported. The system's execution flow is shown in the activity diagram from start to finish as shown in Figure 3.4.

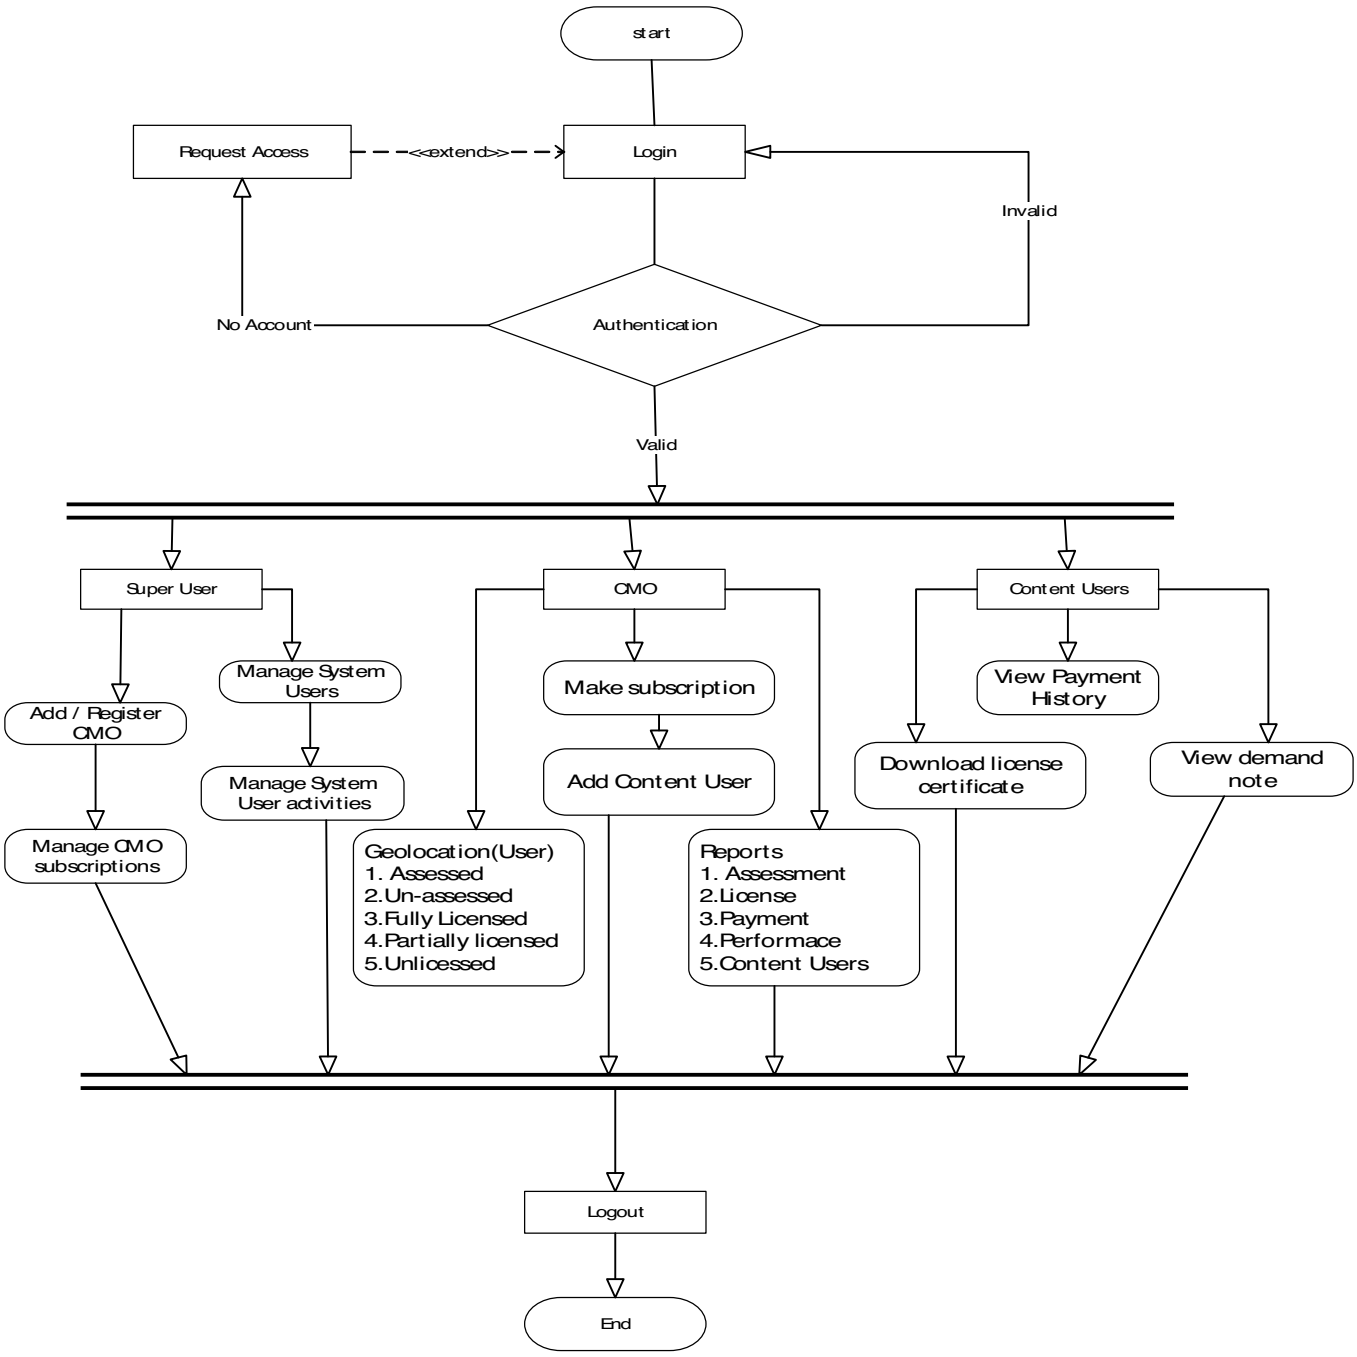

Figure 3.4. Activity diagram

3.8.2 Input Design

The input design shows the template for the user's input. Data is entered into the system through the input form. The licensing officers enter data through the content user registration form on the mobile application while the admins and licensing manager has separate forms on the web system to manage content users as well as uploading already existing copyright

content users who aren't in the system from their former excel databases as shown in Figure 3.5.

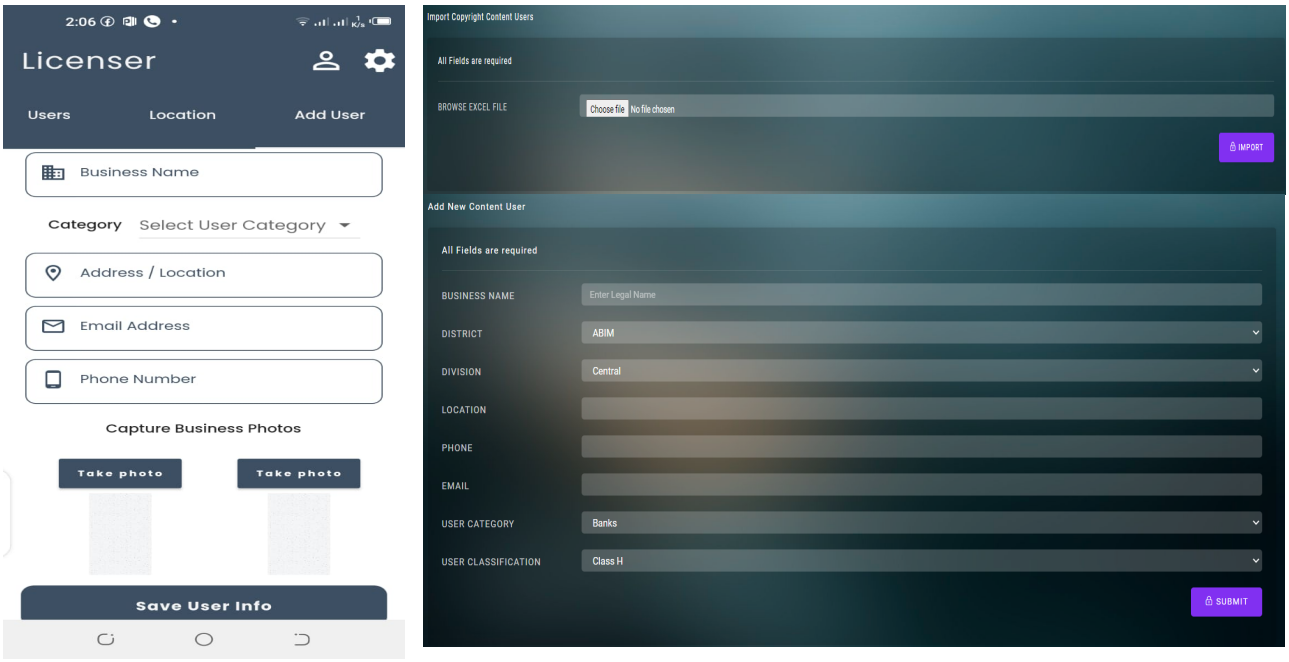

Figure 3.5.Input form for Copyright User Registration on the mobile application and web system

Licensing officers can use the mobile app to login as well as on the web system which is used by other users for example, CMO staff (System Admin, Licensing officer, licensing manager and accountant) and content Users. And they are all required to enter username and password as shown in Figure 3.6

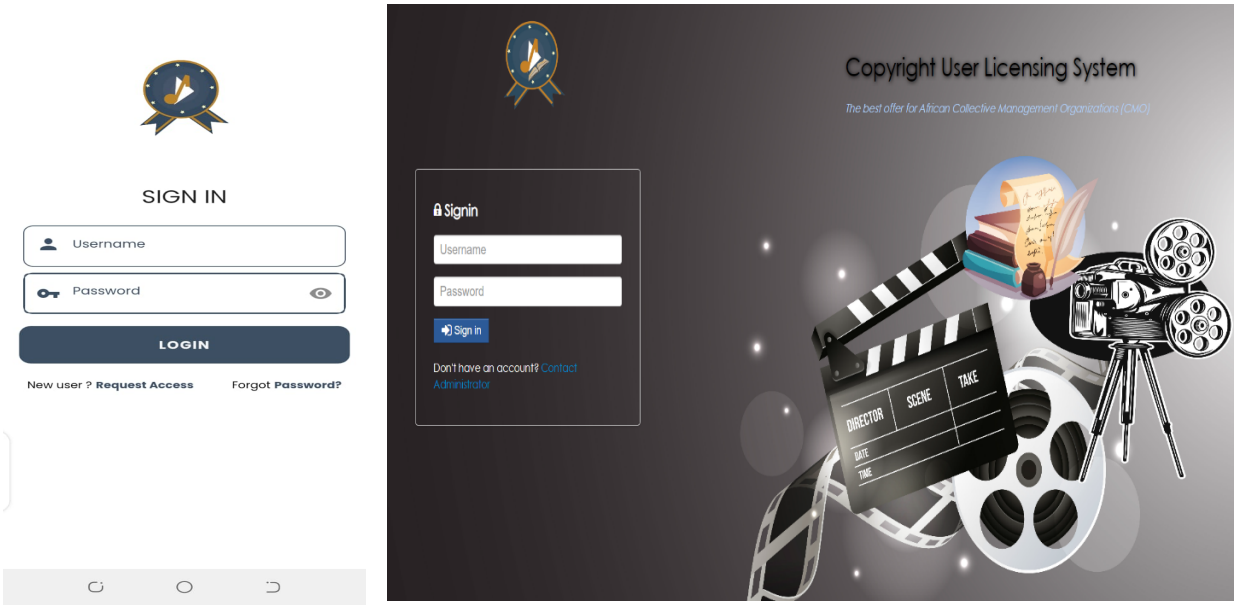

Figure 3.6.Input form for Users Login

The tariff form contains, Name and Tariff Symbol which is captured and the Code is auto generated by the system as shown in Figure 3.7

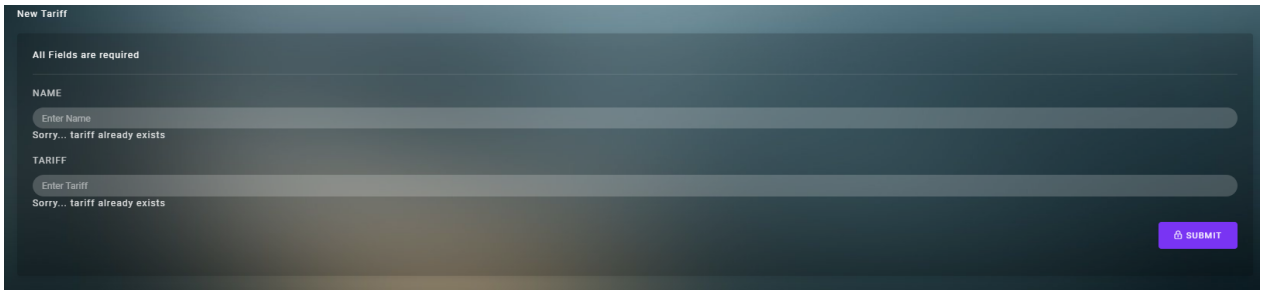

Figure 3.7. Input form for CMO Tariffs

To track the tariff ratings, we captured the user category/sector like, hotel, guest house, then the kind of work like musical work or sound recordings and then the classification represented by the class. And in the table form with auto generated rows ranges are captured as defined in the CMO tariff books as well as the total Fee is also auto calculated as shown in Figure 3.8

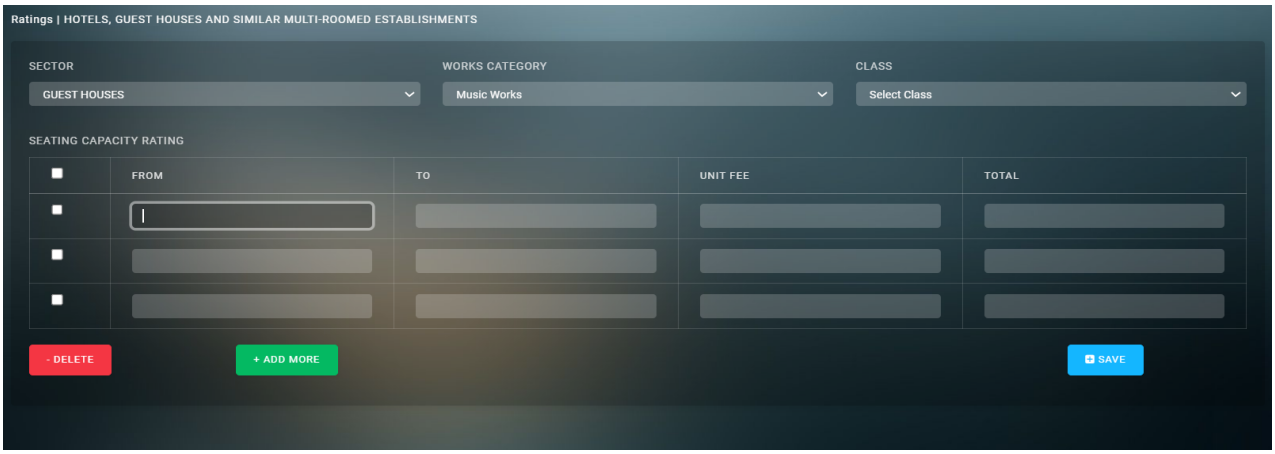

Figure 3.8. Input form for Tariff Rating

User assessment involves the selection of user category, works, classification which will define the units (seating capacity or square meters) used while calculating the fees for that selected content user as in Figure 3.9

Figure 3.9. Input form for Content User Assessment

3.8.3 Output Design

The output design is the design of the results the user expects to get when they login and uses the software. The major thing a copyright content user does with the software is to view annual assessment details alongside the issues demand note, previous payment history and to download their license certificate after clearing the annual fees.

Figure 3.10. Demand Note

The demand note as shown in Figure 3.10 is automatically generated on the copyright user portal/page immediately after their assessment by the licensing officer. And an assessment also displayed as shown in figure 3.11

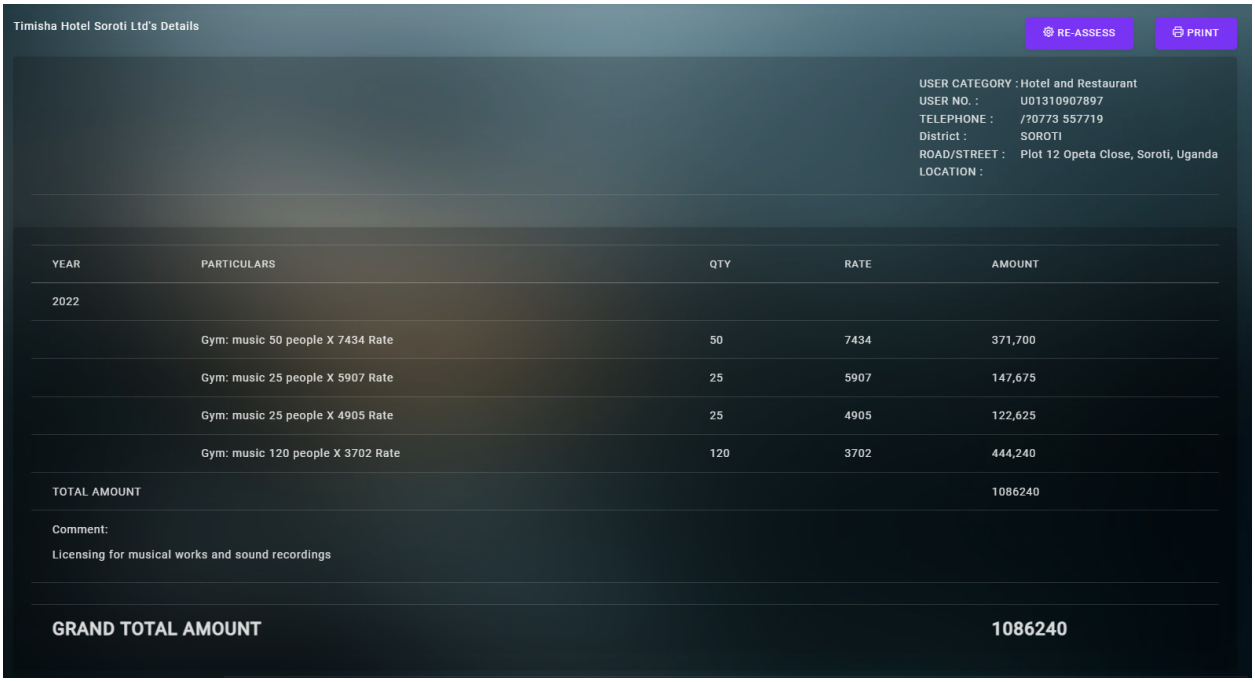

Figure 3.11. Detailed User Assessment Report

The CMO staff, manage users of copyright works, manage user payment, manage licensing and all its processes and manage Tariffing.

Content user management by the CMO administrator involves monitoring, updating or editing user details as well as deleting already existing copyright content user as shown in Figure 3.12.

Figure 3.12. Copyright content users list

One of the first stages of system usage by the CMO administrator , is to deal with the settings which involve adding CMO Tariff, Category and Rating according to the CMO tariff book.

The tariff is added with corresponding user categories under that tariff as well as the tariff rating which outputs a tariff list, user category/sectors list and tariff rating list

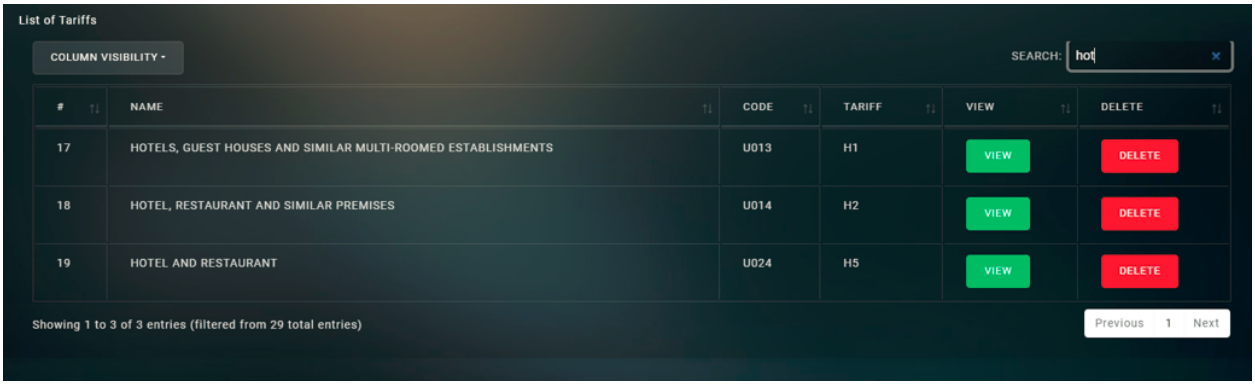

Figure 3.13. CMO Tariff list

Figure 3.13 shows a list of Tariffs for a selected CMO which is searchable by name, code or Tariff symbol

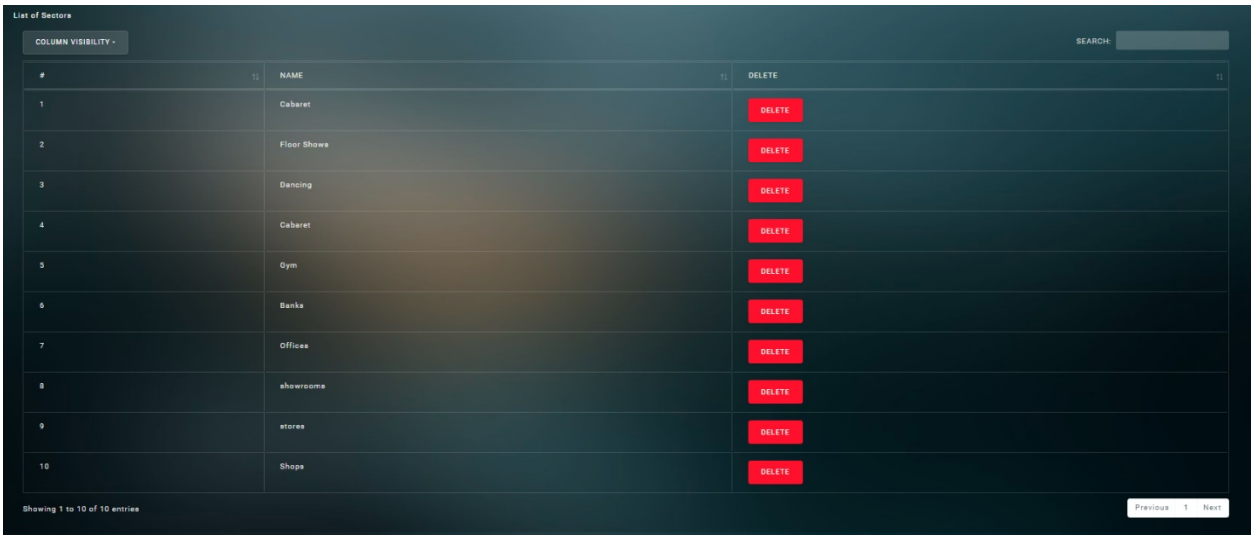

Figure 3.14. User category/sectors list

Each Tariff is used to rate different categories of users also known as sectors which can be displayed on selection of a tariff as shown in Figure 3.14

Figure 3.15.Tariff rating list

After assessing content users, an administrator manages all the assessments done by all the licensing officers in a CMO as shown in Figure 3.16.

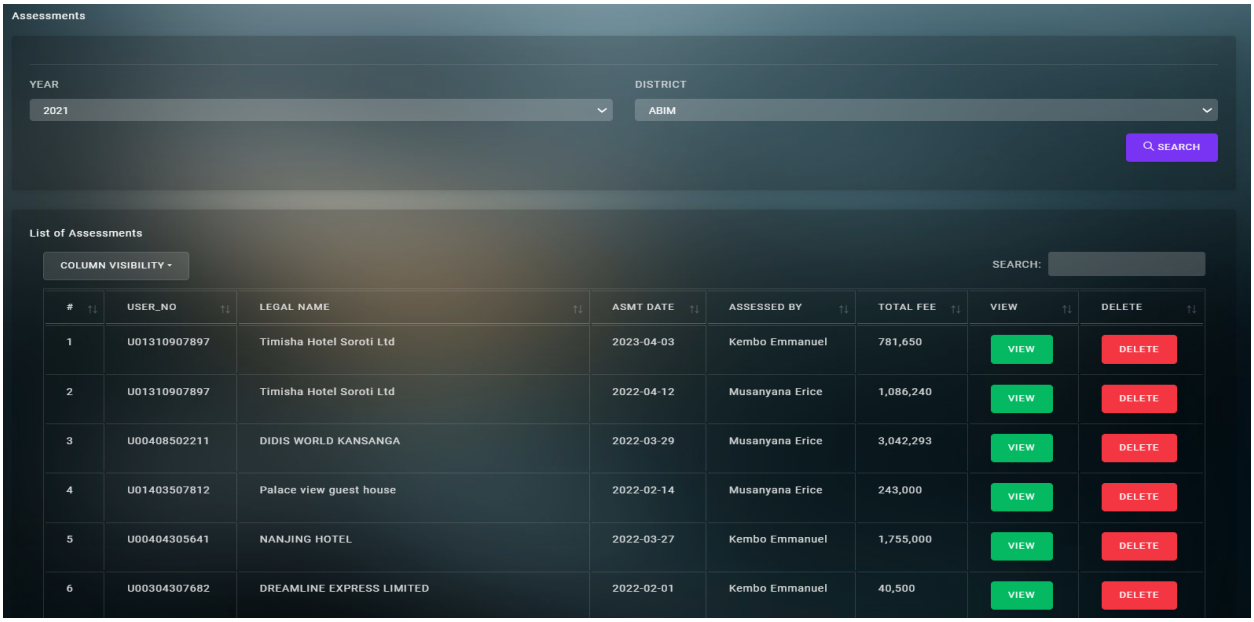

Figure 3.16.Copyright content users Assessment list

3.8.4 Database Design

Database is a collection of entities with related information. In the design of the course registration and result process system, the various related entities are: asmt_particular, assessment, cmo, content_users, country, demand_note, district, division, license_officer, payment, subscription, tariff_category, tariff_rating, teriff, users, works as shown in Figure 3.17.

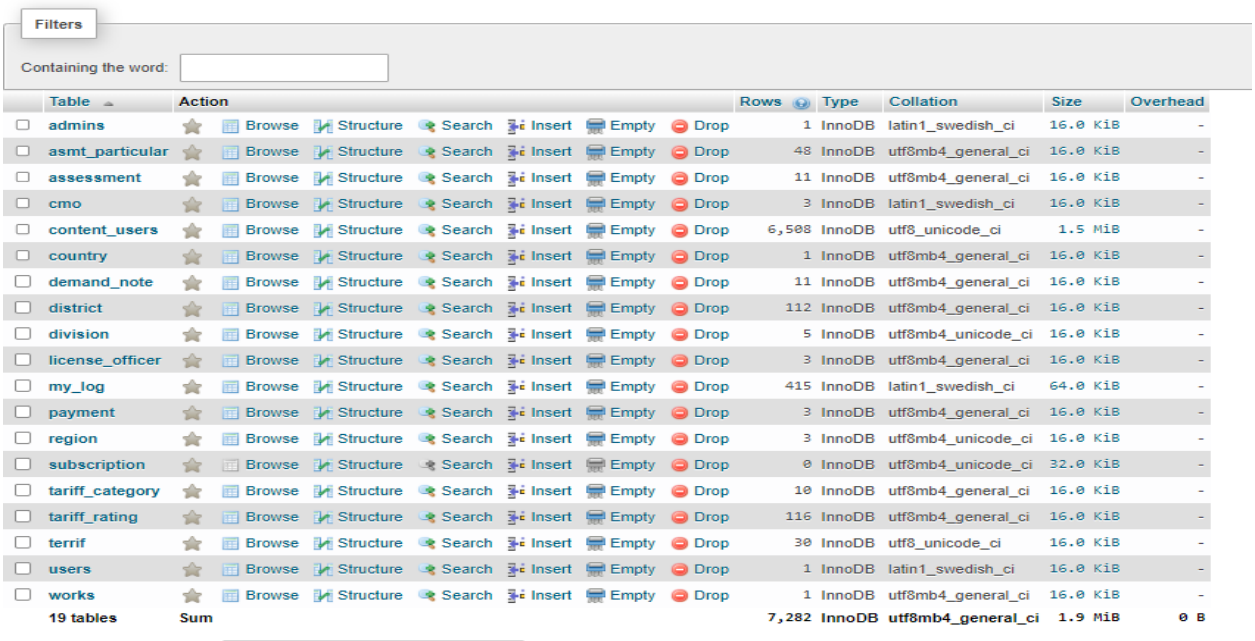

Figure 3.17.Screenshot of the Database tables

The Copyrights User Licensing model has data schema of the database design, which consist of 11 main tables as represented in the database relationship design in Figure 3.18.

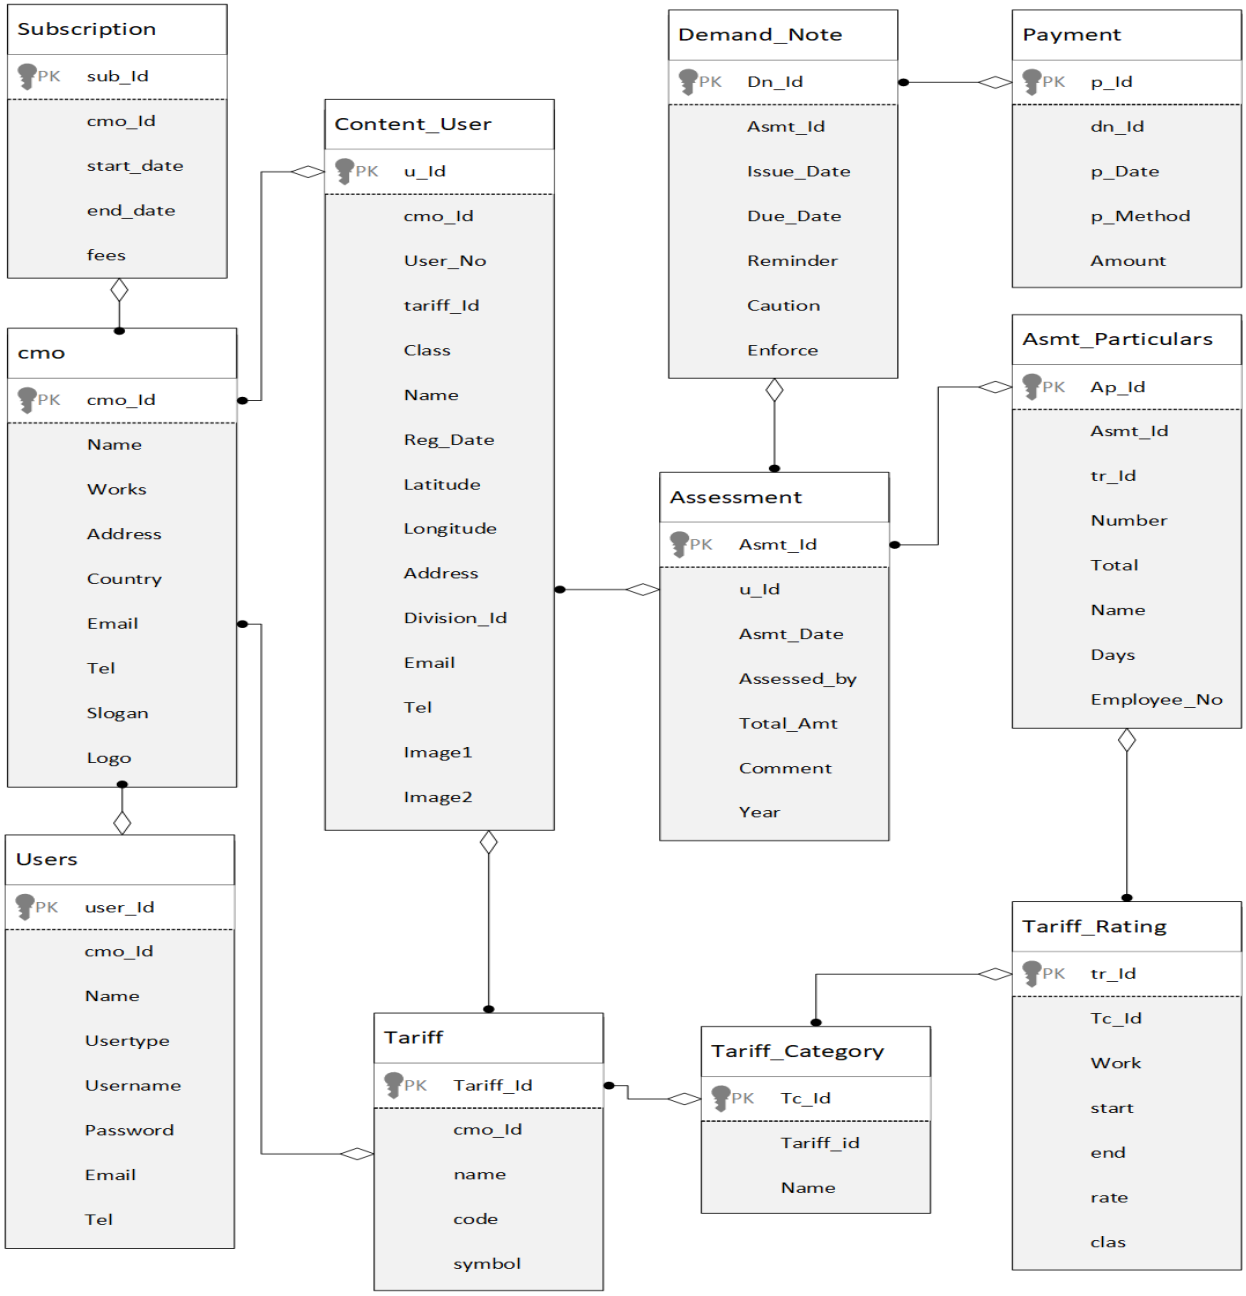

Figure 3.18.Copyrights Licensing model Relationship Design

Apart from CMO table, all other tables the system are linked by the foreign key as follows:

Table 3.4.Primary Key and Foreign Key of Each Table

Table Name	Primary Key	Foreign Key
CMO	Cmo_Id	
Users	User_Id	Cmo_Id
Content Users	U_Id	Cmo_Id,tariff_Id
Tariff	Tariff_Id	Cmo_Id
Tariff_Category	Tc_Id	Tariff_Id
Tariff_Rating	Tr_Id	Tc_Id
Assessment	Asmt_Id	U_Id
Asmt_Particulars	Ap_Id	Asmt_Id, Tr_Id
Demand_Note	Dn_Id	Asmt_Id
Payment	P_Id	Dn_Id

3.9 Data Dictionary

The data dictionary includes the database fields and relationships, as well as the types of data .This helps in creating the database of the system and to understand how data is related to each other in the system database.

Table 3.5.Data Dictionary: CMO Table

Field Name	Type/size	Required	Primary Key	Foreign Key
cmo_Id (Primary)	int(12)	Yes	Yes	No
name	varchar(50)	Yes	No	No
address	varchar(50)	Yes	No	No
email	varchar(50)	No	No	No
phone	varchar(50)	Yes	No	No

country	varchar(50)	No	No	No
logo	varchar(50)	No	No	No
works	text	Yes	No	No
slogan	text	Yes	No	No

The database constitutes a table named CMO which stores all the key information captured from a CMO during the time of registration. And the key fields captured from CMOs are showed in Table 3.5.

Table 3.6.Data Dictionary: Assessment Particulars Table

Field Name	Data Type & Size	Required	Primary Key	Foreign Key
id (Primary)	int(12)	Yes	Yes	No
asmt_Id	int(12)	Yes	No	Yes
work	text	Yes	No	No
number	int(12)	Yes	No	No
fee	int(20)	Yes	No	No
total	int(20)	Yes	No	No
name	text	Yes	No	No
days	int(10)	No	No	No
employee	int(12)	No	No	No

The assessment particulars table holds the assessment details of a particular work category for a specific assessment. An assessment is identified using asmt_Id which is a foreign key as shown in Table 3.6

Table 3.7.Data Dictionary: Assessment Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
id (Primary)	int(12)	Yes	Yes	No

u_Id	int(12)	Yes	No	Yes
asmt_date	varchar(20)	Yes	No	No
assessed_by	varchar(100)	Yes	No	No
total	int(12)	Yes	No	No
comment	text	Yes	No	No
year	int(10)	Yes	No	No

During the process of user assessment, the user assessment data is stored in the assessment table and the key fields captured during this process is shown in Table 3.7

Table 3.8.Data Dictionary: Copyright Content user Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
u_Id (Primary)	int(20)	Yes	Yes	No
user_no	text	Yes	No	Yes
cmo_Id	int(12)	Yes	No	Yes
tariff_id	int(12)	No	No	Yes
regn_date	text	No	No	No
legal_name	text	Yes	No	No
latitude	text	No	No	No
longitude	text	No	No	No
tel	text	No	No	No
email	text	No	No	No
division_id	int(12)	Yes	No	Yes
address	text	Yes	No	No
image1	text	No	No	No
image2	text	No	No	No

clas	varchar(5)	No	No	No

Before assessing a copyright content user, registration is first done and during this stage the information shown in Table 3.8 is captured from them and stored in content_user table of the database.

Table 3.9. Data Dictionary: Demand Note Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
id (Primary)	int(12)	Yes	Yes	No
Asmt_Id	int(12)	Yes	No	Yes
date_issued	text	Yes	No	No
due_date	text	Yes	No	No
reminder	text	No	No	No
caution	text	No	No	No
enforce	text	No	No	No

The demand_note table store content users demand notes generated by the system after assessment process is done. The fields stored on the demand note details shown in Table 3.9 are captured at this stage.

Table 3.10.Data Dictionary: CMO Licensing Officers Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
id (Primary)	int(12)	Yes	Yes	No
cmo_id	int(12)	Yes	No	Yes
Name	text	Yes	No	No
Email	text	Yes	No	No
Tel	int(20)	Yes	No	No

Address	text	Yes	No	No
Region	text	Yes	No	No

Every CMO has its own licensing agents or officers which are identified by cmo_Id , a foreign key in licensing _ officer table. Other contents captured from licensing officers during registration are shown in Table 3.10

Table 3.11.Data Dictionary: Payment Table

Field Name	**Data Type & Size**	**Required**	**Primary key**	**Foreign key**
id (Primary)	int(12)	Yes	Yes	No
dn_Id	int(12)	Yes	No	Yes
p_date	date	Yes	No	No
p_method	text	Yes	No	No
Amount	int(12)	Yes	No	No

The payment table stores the payments made by the content users which are captured by always the accountants in respective CMOs. The fields captured during this process are shown in Table 3.11 with demand note ID (dn_id) which is a foreign key to connect it to demand note table

Table 3.12.Data Dictionary: CMO Subscription Table

Field Name	**Data Type & Size**	**Required**	**Primary key**	**Foreign key**
sub_Id (Primary)	int(12)	Yes	Yes	No
cmo_Id	int(12)	Yes	No	Yes
start_date	date	Yes	No	No
end_date	date	Yes	No	No
Fee	int(12)	Yes	No	No

CMO subscription table stores the details of the subscriptions made by CMOs all managed by the superAdmin of the system. The fields captured for this process are shown in Table 3.12 and cmo_ID is used as the foreign key to identify each cmo subscription.

Table 3.13. Data Dictionary: Tariff Rating Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
tr_id (Primary)	int(12)	Yes	Yes	No
tc_Id	int(12)	Yes	No	Yes
work	Text	Yes	No	No
start	int(12)	Yes	No	No
ending	int(12)	Yes	No	No
rate	int(12)	Yes	No	No
clas	Text	Yes	No	No
sector	text	Yes	No	No

Each CMO tariff has corresponding Tariff rating which act as a guide in the process of calculating fees to respective user categories. Therefore the Tariff rating table stores the details of respective tariff ratings for each cmo and the fields captured are shown in Table 3.13.

Table 3.14. Data Dictionary: Tariff Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
id (Primary)	int(12)	Yes	Yes	No
cmo_id	int(12)	Yes	No	Yes
name	text	Yes	No	No
code	int(12)	Yes	No	No
tarrif	varchar(20)	No	No	No

Tariff represent usage groups of copyright contents, the tariff table stores tariff of all respective CMOs, the fields captured from the cmo tariff are shown in Table 3.14.

Table 3.15. Data Dictionary: System Users Table

Field Name	Data Type & Size	Required	Primary key	Foreign key
user_Id (Primary)	int(10)	Yes	Yes	No
cmo_Id	int(12)	Yes	No	Yes
name	varchar(30)	Yes	No	No
username	varchar(20)	Yes	No	No
password	varchar(32)	Yes	No	No
tel	varchar(15)	Yes	No	No
Email	varchar(50)	No	No	No
user_type	varchar(60)	Yes	No	No

The system users are captured by system administrators of any subscribed CMO and superAdmin, this data is stored in user table and during registration the fields captured are shown in Table 3.15.

3.10 Description of validation technique(s) for proposed solution

System validation is an important aspect of the system development life cycle since it ensures that your system meets the needs of its users.

User testing and heuristic evaluation are two validation methodologies employed in the proposed solution.

i. User testing entailed users checking out the suggested solution's built prototype and offering feedback on their experience. This made it possible to identify usability concerns more quickly and effectively.
ii. Heuristic evaluation: A team of experts, including licensing agents and CEOs, reviewed the prototype for usability difficulties. These were quick and simple to carry out, even if they may not have identified all usability concerns.

The focus of testing both the web application and the mobile application was on user interface and the various data that the mobile application collected and analyzed using the web application. The project concentrated on how users navigate through the system while performing their daily tasks. This was then used to assess the system's efficiency in terms of meeting user requirements. We also tested whether users could easily find the information they needed on the web or mobile app.

For example, the main focus was on audio visual works CMOs, and content users, under the supervision of Uganda Federation of Movie Industry, one of Uganda's key CMOs, which enabled the researcher to capture all of the required information from all users, and this information was also easy to edit and thus provide recommendations.

These concerns centered primarily on the systems identified scenarios. The test was conducted both online and locally for users outside of Uganda, but the emphasis was on local user testing because the researcher was acting as a copyright Inspector, allowing him to interact physically with all users.

Emails, social media platforms like WhatsApp, and physical requests were used to request testing because the researcher was physically in contact with the users. The CEO, who was the focal person at the CMOs, was supposed to complete the participant requirement because they were the primary users during the project testing. The CEOs, Licensing Managers, Licensing Officers, and CMO administrators served as test participants. The researcher spoke with the CEO in person to help advice all staff to pay close attention to the project testing. First, an interview with the focal person at the CMO facility was conducted to determine whether the system meets the users' objectives.

This aided in the collection of qualitative data, which was used to generate the results. A laptop and an internet-connected mobile device were among the tools used.

3.11 System Architecture

Copyright User licensing architecture shows a diagrammatic representation of all major components involved in the software and their linkages. In this project, only three user types are guaranteed access

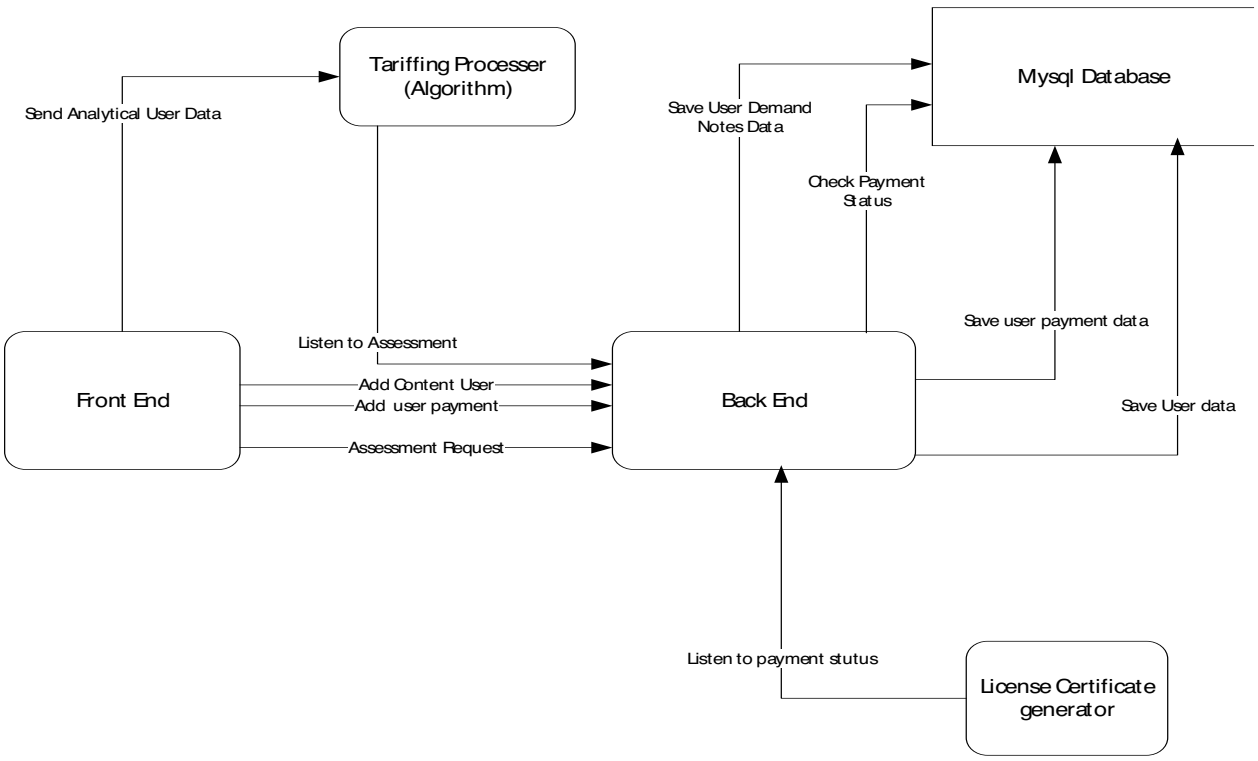

Figure 3.19. Architecture of Copyrights Licensing model

According Figure 32, the Front end represents the user interfaces that is what the user interacts with, the Back end represents the engine of the system with connections to data store and processing APIs for interpreting CMO tariff.

First the front end (Licensing agent) will register or adds the new content user details whose data will be saved in the MYSQL database.

Secondly, the front end (Licensing agent) will request assessment of a user on selection of a content user, with the help of the captured the user type (i.e. hotel, bar) during the content user registration, the backend calls the Tariffing processor API, and displays the key fields to be captured from that type of user i.e. number of rooms, or number of seats or dimensions and etc. According to the measurements or quantity from the front end the backend will auto generate a quotation and the amount with its details which will be saved to the database and then sent back to the front end to be viewed by the licensing agent, accounts office and content user.

The process of listening to payment status event and saving payment details in the database by the backend will be dependent on the user payment data captured from the front end.

Front end once the payment status has been confirmed (fully paid) by the backend, next is generation of content user license certificate by the system which is downloadable at the content user front end.

3.12 Evaluation Matrices

The metrics enabled a thorough review of the copyright user licensing system from several viewpoints, allowing companies to discover areas for development, make educated decisions, and align the system with the overall goal. Defect metrics was used and helped in understanding the many aspects of software quality. Among the defect metrics used include the following: -

i. **Availability:** This involved measuring the system's uptime or the percentage of time it is operational and accessible to users. It reflects the system's reliability and can be expressed as a percentage.
ii. **Reliability:** This involved measuring how often the system is available and able to perform its intended functions.
iii. **Performance:** This involved the measuring of how quick and efficient the system can process data and requests performed or made by the system user
iv. **Response Time:** The system response time while interpreting the tariff and allocating fees to content users as key operation was determined. This indicated the system's speed and was measured in milliseconds or seconds, depending on the context.
v. **Error Rate:** This quantified the number of errors or failures encountered by the system during a specific period. It included various types of errors, such as crashes, timeouts, exceptions, or incorrect outputs. The lower error rate indicated higher system stability and quality.
vi. **Scalability:** Scalability measured the system's ability to handle increasing workloads or accommodate growing numbers of users without a significant decrease in performance. It assessed how well the system can scale up or scale out to meet increasing demands.
vii. **Security:** This involved assessing the system's security posture and the effectiveness of its security controls. They included measuring of how well the system protects data from unauthorized access, use, disclosure, disruption, modification, or destruction.
viii. **User Satisfaction:** This involved capturing users' feedback and perceptions about the system's usability, functionality, and overall performance. This was measured through an

online survey (google questionnaires) to gauge user satisfaction and identify areas for improvement.

The metrics provided a comprehensive evaluation of the copyright user licensing system from different perspectives, enabling organizations to identify areas for improvement, make informed decisions, and align the system with main objective

Chapter 4 : Result and Discussion

4.1 Preamble

The purpose of this study was to develop a copyright user model for CMOs. A total of 11 prototype testers including 2 CEOs from different CMOs and the remaining 9 where licensing officers were randomly assigned to access and test the developed prototype of the model. The testers were followed for 3 days after training them on how to navigate through the system, and after google doc questionnaires link was shared to get feedback about the designed model.

The results showed that the newly developed copyright user licensing model was significantly more effective than any existing Copyright user licensing model in managing the licensing processes of content users by CMOs.

4.2 System Evaluation

System evaluation is the practice of evaluating a system's performance to its specifications. It is a critical component of the system development life cycle (SDLC) and can be performed at any stage of the SDLC. System assessment is performed to ensure that the system is efficient in achieving its goals and that it meets the needs of its users. An assessment of a system can also be used to identify areas for improvement.

The key method of evaluation used in the proposed solution was System testing. System testing was used to assess the performance of the system. This testing was performed by the development team, licensing officers or agents and CEO for respective CMOs.

Therefore, for evaluation of the proposed system different system tests were performed. The three stages of testing have the following purposes:

i Unit test – the smallest testable elements of the system were tested individually, typically at the same time those elements were implemented. Each model was compiled and executed for unit test and most focus was put on Tariff Rating and assessment of copyright content users.

ii Integration test – the integrated models are tested, such as add new Tariff Rating per tariff as well as assessing content users depending on a specific Tariff.

iii System test – The complete application and system (one or more models) were tested. The whole system was tested for the functionality and integrity.

4.2.1 New CMO creation

The superAdmin as the role of approving and managing all the CMO which have subscribed to the system. As shown in Figure 33, CMO name, addresses, phone number, email country, an automated license date and selectable license expiry date and the tagline or slogan of that CMO are among the key details captured from a CMO.

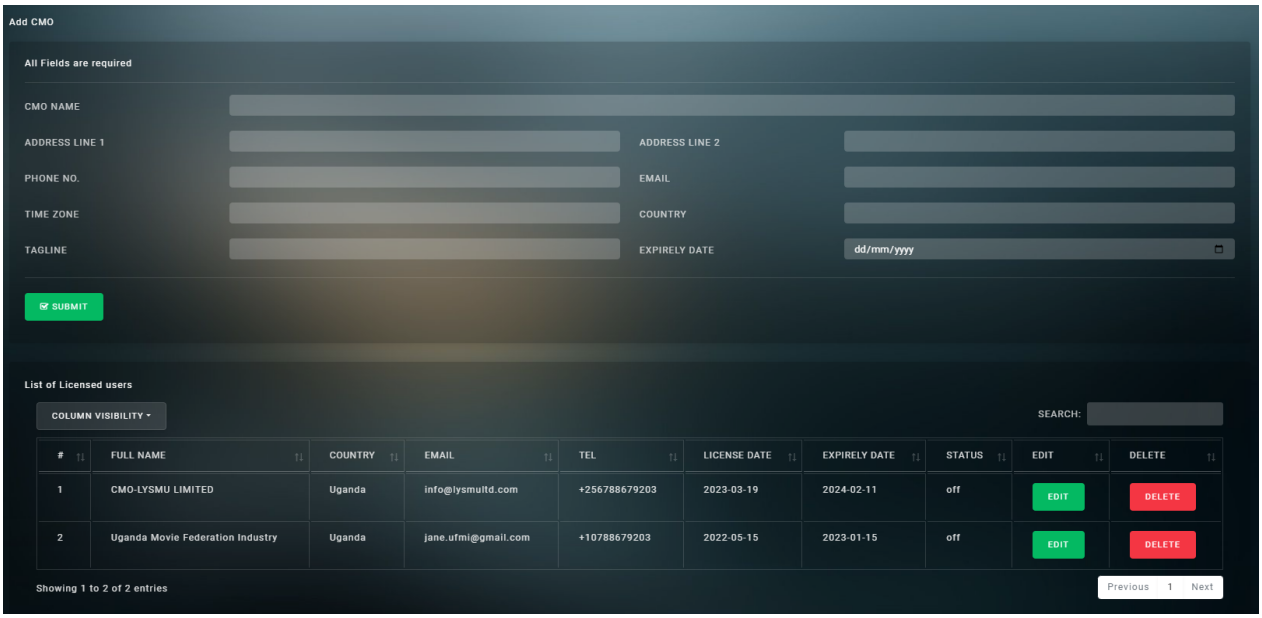

Figure 4.1.CMO Registration and Details

In the process of adding the CMO, a CMO is automatically allocated a unique identification which is being used by all members, content users under it, tariffs as all tables with in the database are dependent on the CMO table. Addition and management of a CMO was tested individually by the system superAdmin.

4.2.2 Add Tariff and Rating

Tariff categorize the licensing schemes of each individual CMO, after a CMO is being approved to use the system, the users under the CMO with administrative and Licensing manager user roles are capable of managing the Tariff and their respective ratings. The system is capable of checking for already existing Tariff as well as their rating to avoid double entry of information hence bringing out clear data accuracy.

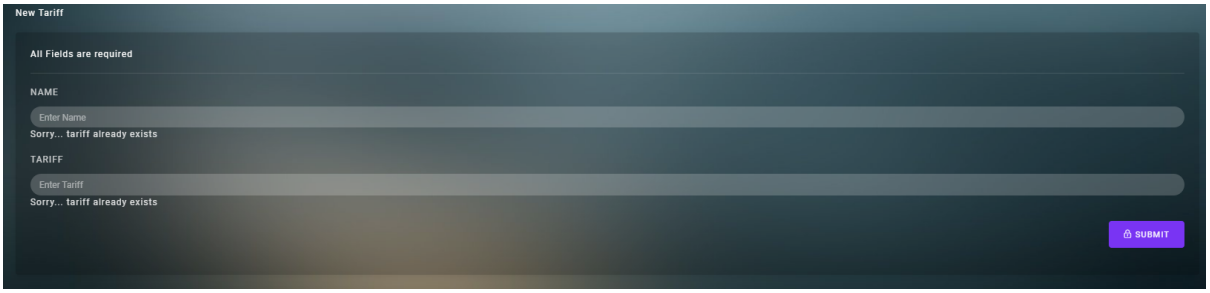

Figure 4.2. Check Tariff Availability

As shown in Figure 34, if Tariff was already added, the system displays an error message “Sorry tariff already exit” before it’s saved in the database

4.2.3 Unrated Tariff Test

Every CMO has its own individual Licensing Tariffs depending on the category of works they protect on behave of their members. And each added Tariff has a corresponding rating depending on the units used for measurement. There if the tariff is viewed and it is not rated, an error message will prompt.

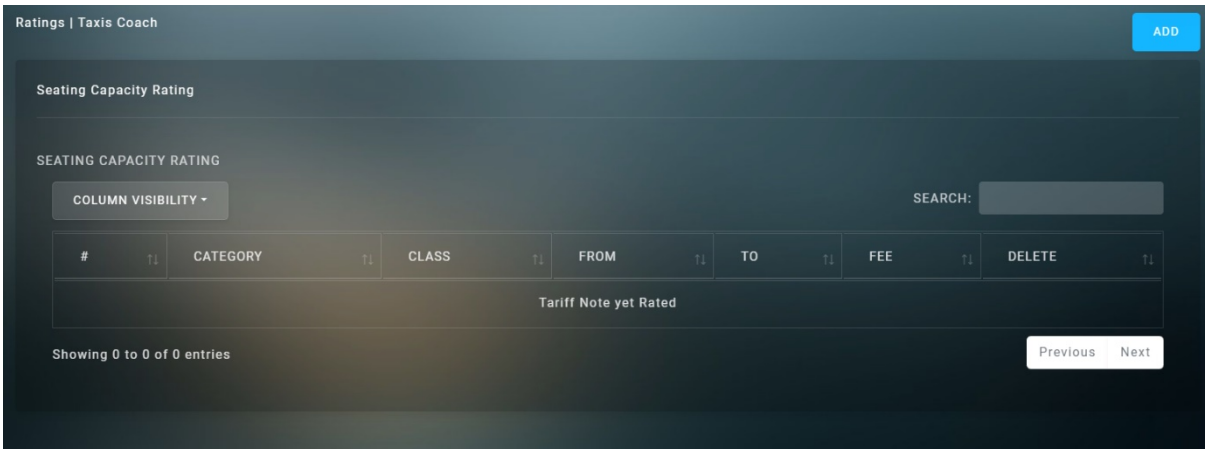

Figure 4.3. Unrated Tariff

As shown in figure 35, Taxis Coach Tariff for a CMO which handles musical works has been rated, on viewing its details it gives a message of Tariff Not yet Rated with an empty table of seating capacity.

This testing is directly done with individual licensing officers of each individual CMO fully supervised by the Licensing Manager.

4.2.4 User Assessment under unrated Tariff

User assessment is dependent on licensing Tariff, a user can be assessed using one or more tariff depending on the particulars they have. An example of a hotel as a content user may have a bar, hotel rooms, functions, beach as particulars but all these particulars are handled by different Tariffs while assessing.

If a particular is selected to be assessed the system will communicate with the tariff API which checks the rating accordingly. For the case if the rating to the corresponding particulars is not found a popup error message will show.

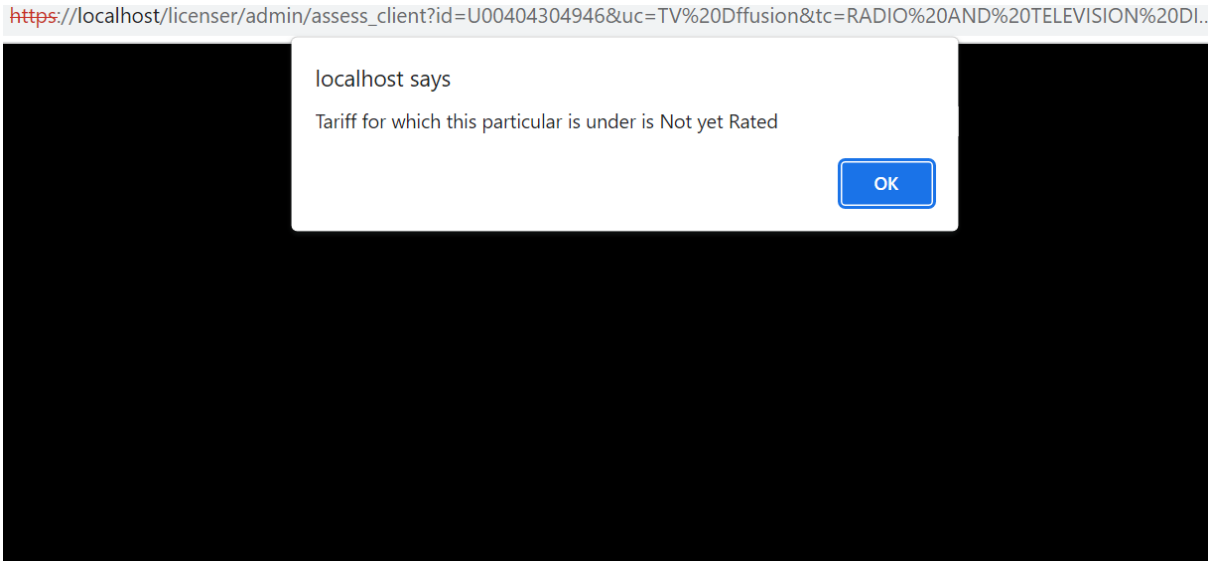

Figure 4.4. Error message for unrated Tariff

As shown in Figure 36 the error message “Tariff for which this particular is Not yet Rated” enables the CMO Licensing agents and manager to fully rate their Tariffs accordingly for efficiency of the licensing process.

In conclusion all these Tests are done with the members in the copyright ecosystem to check the integrity and efficiency of the system.

4.3 Results presentation

Designed Google forms questionnaires were utilized to collect and portray the results offered by system testers after engaging with the built prototype. We used Google form questionnaires to collect input, with key options of strongly agree, agree, strongly disagree, disagree, and the results are shown below.

Question 1; The interface of the application is user-friendly

One of the goals of user evaluation was to find out whether the designed system was user friendly to the users. The below figure 37 shows the results from the participants.

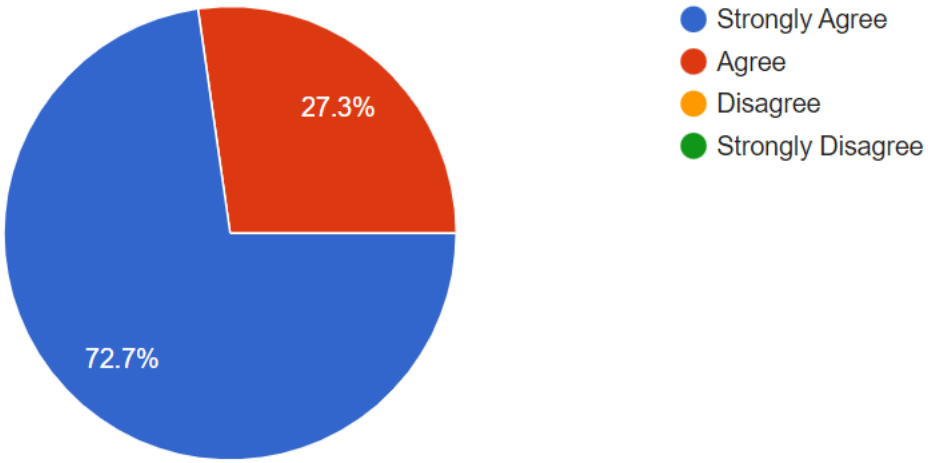

Figure 4.5. Feedback from question 1

Question 2; The application design is easy to navigate

In this thesis we also wanted to find out the navigation on the designed system. The figure 38 shows the feed

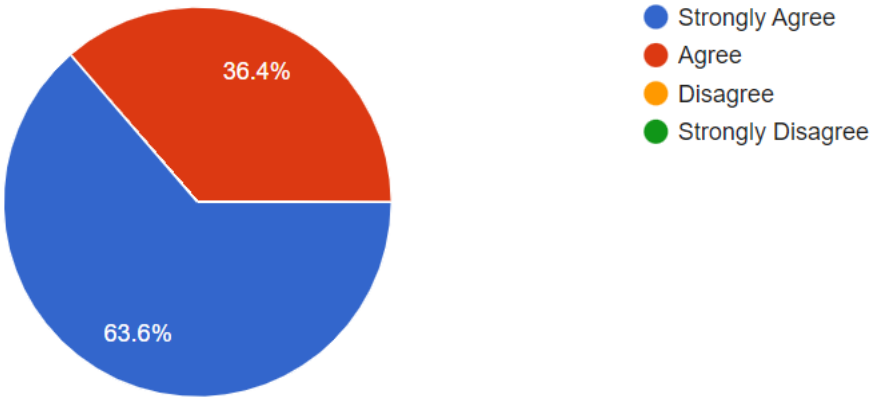

Figure 4.6.Feedback from question 2

Question 3; There is too much inconsistency in the Tariff Interpretation by the system

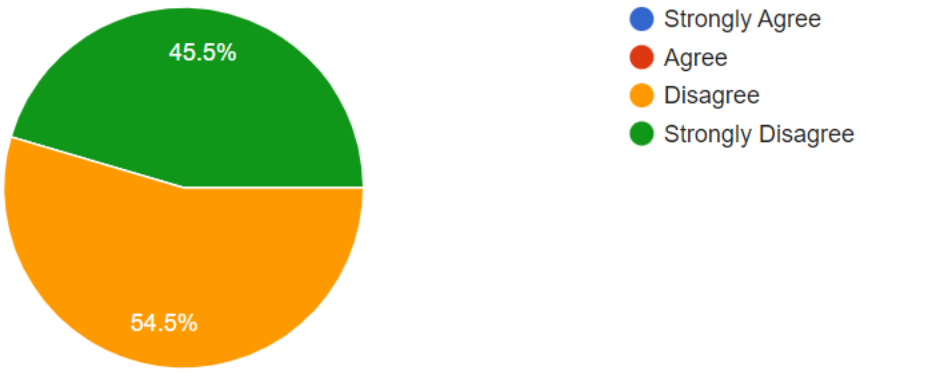

Figure 4.7. Feedback from question 3

Question 4; The designed system is easy to use and faster to locate copyright content users

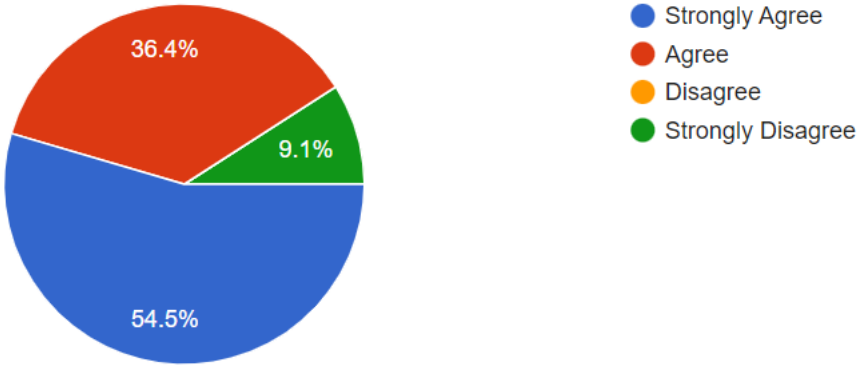

Figure 4.8. Feedback from question 4

Question 5; The system reduces the time taken to assess and assign fees to copyright content users

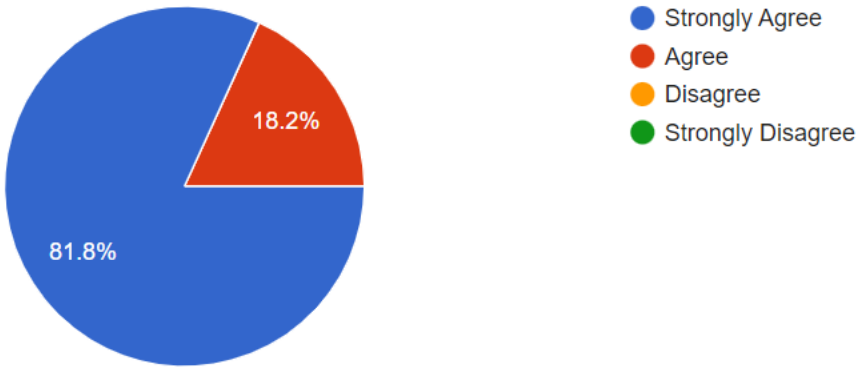

Figure 4.9.Feedback for question 5

Question 6; It is very easy to find information on the designed system. In this question we wanted to understand the usability in terms of how to improve the interface such that users are able to find all the information

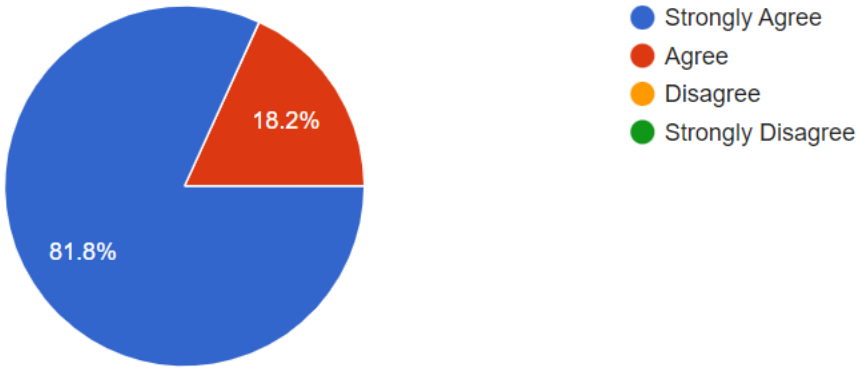

Figure 4.10. Feedback for question 6

Open ended Question 1; what do you think should be improved in the designed system?

The participants commented on trucking of copyright holders who have not made the payments due assigned to them as well as providing multiple selectable designs of licensing certificates for CMO .In addition , there is need to examine the data quality checks within the system, which are mostly drawn from the Tariff rating, and looking at incorporation of user payment methods such as mobile money and bank accounts into the system as well as considering training of the system users, particularly administrators tasked with setting up the key contents system.

And finally looking at enabling the mobile application to work with or without internet as well as adding in system warnings or notifications when the user should clear the cost, or when the CMO needs to terminate the content user if payments are not made.

Open ended Question 2; Is there anything you would like to comment on the current nutrition assessment process?

Participants provided input on the application's ability to aid in real-time data collecting and assessment, as well as the licensing of copyright content users. They also commented on how simple the system is, which I strongly encourage CMOs to implement. It will save them a lot of

money, it is a good system with great designs and color combinations, and it is the first ever solution for CMOS's primary business, user licensing.

4.4 Analysis of the Results

The process of assessing the data collected during a research effort is known as results analysis. The goals of analysis are to comprehend the relevance of the data and reach conclusions about the study topic. In the copyright user licensing model The results parameters from the tested developed prototype comprised interface user friendliness, ease of navigation within the design, consistency of the system in Tariff interpretation, system ease of use, time taken to perform tasks, and quick information access as shown in Figure 4.11.

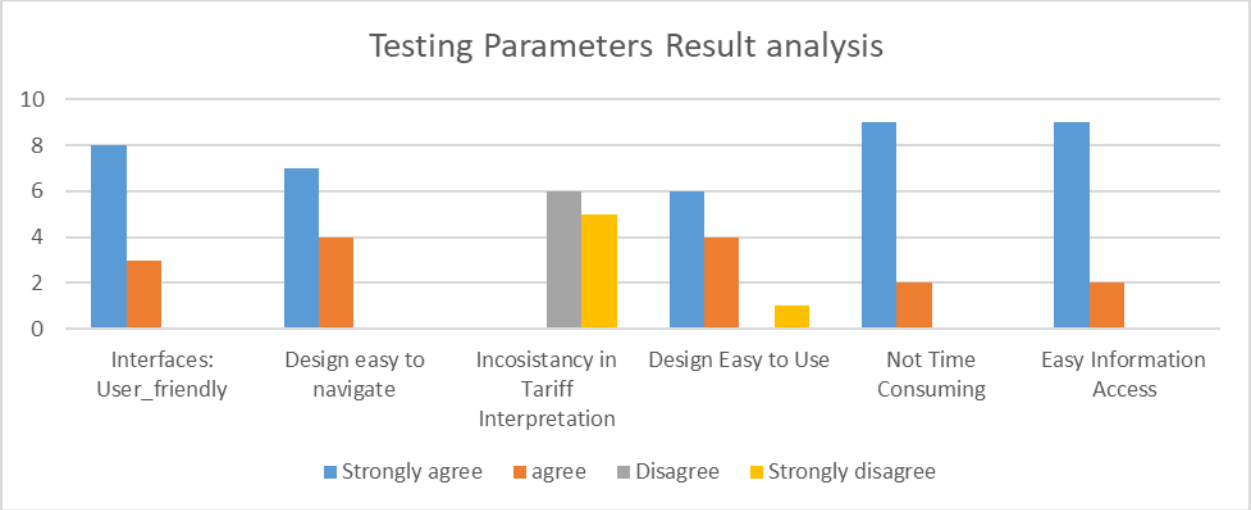

Figure 4.11.Testing Parameters Result analysis

According the Figure 4.11, the highest number of system testers were satisfied with the design most especially with the user interfaces, how ease to navigate while using the system, the system being not time consuming as well as the ease in accessing required information during the licensing process as all respondents agreed and strongly agreed. In addition all respondents denied the system being inconsistent in interpreting the CMO tariffs as they all indicated strongly disagree and disagree. The highest number of respondent strongly agreed that the system is easy to use, followed by those who indicated agree and finally one respondent who strongly disagreed the system being easy to use.

4.5 Discussion of the Results

The researcher created a model to manage copyright user licensing processes for collective management organizations in this study. The model was created in the form of a web and mobile application that people may engage with. CMOs in Uganda, like our case study, were mostly utilized for physical prototype testing with the researcher, who was also capable of performing usability assessment. The online system was hosted as a subdomain of the lysmultd.com domain (culs.lysmultd.com), and the resulting android APK was directly shared with the sampled testers, primarily CMO licensing agents, for installation on their android mobile devices. This allowed the created model to be evaluated against several copyright user groups, and the model performance results were obtained and presented in a graphical way for simpler interpretation and analysis. The model's performance was measured in terms of system user utilization, tariff interpretation, and charge allocation time, which are all essential parameters for this model. The model was evaluated for three days with CMO stakeholders, and a google doc questionnaire link was distributed to all persons chosen to test the system. As presented in the user feedback shown in Figure 4.11, the main focus of discussion was on the following:-

System efficiency, the model was designed to manage all aspects of copyright user licensing, including copyright user data management, usage assessment management, tariff interpretation, copyright user location, payment management, and license certificate allocation. The user friendliness and ease of system navigation, as well as uniformity in interpreting the CMO tariff, were essential components that represented the system's efficiency, since all testers agreed on the corresponding components. The CMO stakeholders identified the system as meeting all of the requirements for the copyright user licensing procedure and deemed the model to be efficient.

Tariff Interpretation Speed and fees allocation time, the model's primary task is to interpret the CMO tariff based on the user categories; the system easily and consistently interprets the tariff and allocates an annual fee at the fastest possible speed because it only requires the user to click a button after selecting the user to assess and the measurement. Because tariff interpretation and fee allocation are among the most difficult processes confronting licensing officers during fee allocation to copyright users, the task that takes more than 40 minutes by more than two licensing officers (UPRS, 2021) can be completed in one minute or less by the develop prototype

operated by a single licensing officer. This prompted the testers to state unequivocally that the system is consistent and has perfect processing speed.

Data Access, to complete the licensing procedure, many data is required. The key data required includes copyright user data, CMO tariff data, tariff rating data, user payment data, and many others. The majority of this data is kept both locally on the device and externally in the form of an external database. The model makes data available for system users to quickly select in order to complete the licensing procedure. The data is made available based on the user role, as various users have varying levels of access to certain data in the system.

System and Data security, before the testers began interacting with the system, the CMO administrator was registered by the SuperAdmin, who licenses or adds the CMO to the system, and the CMO administrator adds the CMO staffs, primarily the licensing officers, accountants, and licensing managers. After registering, users can log into the system using their usernames and passwords; a verification code is given to the user's phone, which must be provided to gain access to the system; and all of these users can access different information based on their user role or user type. The two-factor authentication and access user role offer the model with high-level data and system protection.

4.6 Benchmark of the results

The enhanced licensed management model allows both online and offline purchases of musical works licenses, so the model only caters to online musical works, leaving other copyright works like movies and books unattended to, so it is only applicable to audio visual CMOs to a limited extent. It provides automatic licensing to online musical works. The strategy becomes onerous for individuals who want many musical works because each work is licensed independently of the others, requiring the user to purchase multiple licenses to use multiple forms of works from separate content owners. Furthermore, CMOs are not considered as actors in the music licensing process, yet they do provide a good new revenue source for creators who are members of a CMO. CMOs can grant content users a wide license that enables them to utilize all copyrighted works, including musical works, because their main legal objective is the collection and distribution of allegiance to their members. For the entire year, a broad license is given to utilize any kind of music in your commercial endeavors.

The copyright user licensing model is adaptable to many types of CMOs, and each CMO can manage their content users, tariffs, licensing processes, employees, and performance. The model includes an API for interpreting any tariff with their accompanying tariff rates for a given CMO uploaded to the database. This allows for rapid copyright user evaluation and licensing. Furthermore, all data such as content user data and tariff data are saved both locally and in an external database and synchronized to provide licensing authorities easier access to data.

Chapter 5 : Summary, Conclusion and Recommendations

5.1 Summary

The new copyright user licensing system is an enhanced automated software that is built to eradicate the major problem inherent in the current system. The development of this system arose because of the low rates of loyalty collection on the alarming growing number of copyright content user distributed all over the country which has led to (no) low financial benefits to copyright content creators.

A study investigated the cause of these problems and conclusion was drawn that the caused by low rate of copyright user assessments and licensing done by CMO and the manual methods used in the copyright user licensing. Therefore the new system targets to curb this situation by building features in the software that could not only produce a better system but mandate CMOs to centrally manage copyright content users and all licensing processes.

In addition, the study into the licensing system exposed the laborious nature of the system; it is time consuming and less effective and nontransparent as most of the key licensing process element like tariff interpretation is manually done by licensing agents. The new system is developed with the capability to automatically interpret any CMO tariff depending on the licensing agents' selection, generation of demand notes as well as licensing Certificates. Having come to completion of this project work a lot of achievement was made and they include;

i. The replacement of error prone manual system with new automated copyright user licensing system.
ii. Data can now be processed with great speed and efficiency.
iii. The system has the ability to interpret the CMO tariff, geo-locate content users as well as licensing agents and generation of license certificates.
iv. The security of data is ensured.
v. The use of database server was implemented.

5.2 Conclusion

The main goal of this study was to develop a copyright user licensing model to improve CMO copyright user licensing procedures such as content user evaluation, geolocation, loyalty collecting, licensing, license certificate user access, and content user data protection and storage.

To achieve this, the current processes used in the licensing of copyright users where studied. This was accomplished by conducting in-person interviews with CEOs and licensing agents from various CMOs, as well as examining CMO annual reports. Furthermore, the researcher traveled with licensing agents in the field to conduct user evaluation and licensing, gaining exposure to all of the procedures involved in the copyright user licensing ecosystem. As a result, all system functional and user needs of a copyright user licensing system were identified, and it was determined that all processes in the copyright user licensing ecosystem are carried out manually.

In addition, a copyright user licensing model was developed using PHP, JavaScript, HTMP and Flutter to improve CMO copyright user licensing procedures such as content user evaluation, location, fee collecting, licensing, license certificate user access, and content user data protection and storage.

The model was designed following an enhanced license management model and the identified system user requirements, the system was designed in the form of a web and mobile application to automate the manual copyright user licensing process. CMOs and involved members tested the prototypes with the researcher and usability assessment was performed. Culs.lysmultd.com, a subdomain of the lysmultd.com domain, hosted the system's online version, and the resulting android APK was distributed directly to the sampled testers, the majority of whom were CMO licensing agents, to be installed on their android mobile devices. This enabled the performance of the developed model to be evaluated using data from a variety of copyright user groups. System user use, tariff interpretation, and charge allocation time were all used to evaluate the model's performance. Each person chosen to test the system was given a link to a Google doc questionnaire, and the model was tested with CMO stakeholders over the course of three days.

It was observed that the model is more efficient and speedier in handling all aspects of copyright user licensing, from user assessment to license certificate generation. The system is 20 times faster than the manual technique in terms of tariff interpretation and charge allocation, as well as locating content users using GPS and retrieving critical information during content user assessment. This means that a vast assessment scope will be covered in the shortest amount of

time feasible, enhancing user licensing coverage and raising the rate of loyalty collection for CMOs, which can be distributed to their members as well as the government via VAT.

5.3 Recommendations

The research recommend that copyright user licensing models be used to improve the user, experience and prevent copyright infringement. Copyright licensing user models can be a valuable tool for managing copyright licenses. They can make it easier for users to find and manage their licenses, and they can help to prevent copyright infringement.

Here are some specific recommendations for how copyright licensing user models can be used:

i. Interpretation of CMO tariffs: the model is geared by an API which accepts any tariff rating, for any user category of a CMO, for easy fee allocation to copyright content users during assessment by licensing officers

ii. User-friendly interfaces: Copyright user licensing model provides user-friendly interfaces that make it easy for users most especially CMOs to find and manage their user licenses.

iii. Automatic license renewal: Copyright User licensing model also automatically renew licenses when the system detects any complete annual payment made and captured by the accounted and license certificate generated.

iv. Copyright infringement prevention: Copyright user licensing model enables faster identification and prevention be able to identify and prevent copyright infringement. As a content user gets one annually license to use any copyright work of that category

As a result, copyright user licensing models have the potential to transform the way copyrighted products are licensed and handled. Copyright user licensing models can serve to stimulate creativity and innovation while both preventing copyright infringement and protecting the rights of copyright holders by making it easier for users to access and use copyrighted information.

To summarize, the copyright user licensing model offers a more adaptable, cost-effective, and convenient method of licensing copyrighted information. The model is significant in the ecosystem of copyright user licensing.

5.4 Contributions to Knowledge

The study has significant contributions to knowledge in several areas. Here are some specific contributions:

First, a new framework for copyright user licensing was designed, which included automation of the manual processes involved in the copyright user licensing ecosystem, with CMOs serving as the primary actors. The framework may make it easier for copyright holders to make their works available to consumers via CMOs, as well as minimize the amount of copyright infringement case.

Second, a new software tool for copyright content user licensing for collective management organizations in Uganda was developed. The software is available in both web and mobile (android and IOS) versions, with the mobile version primarily used by licensing agents during the assessment process in the field and the web version primarily used for management and administration.

Third, a new revenue stream for copyright content providers or authors was introduced, with CMOs always distributing loyalty to their members. As a result, the number of content creators joining respective CMOs is growing. Because the program boosts the rate of loyalty collecting, members are more confident sure of their loyalty, which is an economic benefit expected from their works.

Finally, a new central database on copyright content users that any CMO in Uganda can access. The information acquired from content users by licensing officers of respective CMOs is kept in the built database during the process of user assessment utilizing the software tool provided. This allows for speedier access to content users' data during licensing, resulting in faster licensing.

5.5 Future Research

According to the study, any CMO that wants to increase the rate of loyalty collection and any future development should modify the implemented CMO Licensing system for copyright material consumers. Furthermore, the researcher urges the CMO administrator in charge of creating Tariff ratings must be conversant with the measurement units stated in the Tariff for each user category.

In the future, the researcher recommends implementing a payment model in conjunction with this licensing model so that content users can make payments within the system. Additionally, the researcher recommends implementing an automated tracking of copyright works usage by some unique users such as radio stations and other broadcasting stations because it is difficult to truck copyright content usage.

Project Supervisor Recommender System for Students: A Machine Learning Approach

Stanley Abiodun METIBOGUN (ACE21130013)

M.Sc. Management Information System

A Thesis submitted to the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), in partial fulfilment of the requirements for the Award of Masters of Science Degree in Management Information System.

Department of Management Information System, Africa Centre of Excellence on Technology Enhanced Learning, National Open University of Nigeria.

October, 2023

DECLARATION

I hereby assert that the research work presented in the Thesis, titled "Project Supervisor Recommender System for Students: A Machine Learning Approach," is an original piece of research work towards the fulfilment of the requirements for the award of Masters Degree in Management Information System. This thesis has been submitted to the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL) at the National Open University of Nigeria. The research was conducted under the supervision of Dr. Ibrahim Abdullahi and Dr. Usman Ali, both of ACETEL at the National Open University of Nigeria. The text appropriately acknowledges the information obtained from the sources cited, and a comprehensive list of references is also included. The content included in this Thesis has not been previously submitted by me for the purpose of obtaining any other degree from any other academic institution.

Stanley Abiodun Metibogun	.....	30/11/2023 .....
Name of Student	Signature	Date

CERTIFICATION/APPROVAL

This thesis titled "Project Supervisor Recommender System for Students: A Machine Learning Approach" complies with the regulations for attaining the Master of Science degree at the Africa Centre of Excellence on Technology Enhanced Learning (ACETEL), National Open University of Nigeria. It has been deemed acceptable for its significant contribution to knowledge and its adherence to standards of intellectual presentation.

Dr. Ibrahim Abdullahi	……	……
Main Supervisor	Signature	Date

Dr. Usman Ali	……	15/12/2023
Co-Supervisor	Signature	Date

DEDICATION

This research is dedicated to my amazing family. Thank you for the show of love and support.

ACKNOWLEDGEMENTS

What more can I say than give honour to God, who deserves all the glory? For someone who could have passed on just two weeks before the first session's first semester exams. That itself is a story on its own. It is for this reason I'm thankful I didn't just begin, but I finished well.

There is a saying that people come into our lives for a purpose. I am thankful to have met incredible and outstanding individuals along my academic path who have left indelible impressions on me for which I will be ever grateful. My main supervisor, Dr. Ibrahim Abdullahi, and his co-supervisor, Dr. Usman Ali, will be remembered for their enormous contributions during our class facilitations and research work. They assisted me in putting my thinking faculties together to create amazing problem-solving concepts that were exhibited in the research work. They were both crucial in giving direction, mentorship, and resource materials. Despite his busy schedule, Dr. Ibrahim always arranged for us to meet in person in Abuja.

As ACETEL pioneer students, we often had issues that needed to be answered, and our outstanding coordinator at the ACETEL, Management Information System Department, Dr. Juliana Ndunagu, was always available at any time to give advice and clarifications. Thank you, Ma.

I thank all ACETEL facilitators, particularly those from the Management Information System Department, for imparting life-relevant information and experience that will forever be remembered. Thank you to everyone who offered constructive criticism, encouragement, and suggestions to back up my facts and findings during my research proposal presentation. I carefully considered your feedback and used it in the appropriate places, which is reflected in the final work. I'm sure you would be proud I did. Thank you very much for this.
To the staff of ACETEL who have made our journey smooth, especially in offering consultations, organizing online meetings for staff and student interactions, etc., you are all loved. A special thanks goes out to my M.Sc. MIS colleagues for our conversations and idea-sharing during the course of our programme.

My gratitude goes out to my parents, Mr. and Mrs. Metibogun, for their support during my academic career. For your efforts, which I take very seriously, I am really grateful. My greatest motivation for this work comes from my lovely Mayowa and fantastic Asiwaju. You've never failed to make me smile, even when you're not around. You are the best!

ABSTRACT

Project supervisor selection in academic institutions plays a significant role in a student's research output. The selection procedure can be manual, automatic, or hybrid. The manual process has several attendant drawbacks. Automating the selection process does not necessarily have to follow the traditional search and filter methods of document filtering. Supervisors' past scholarly articles are already loaded with relevant keywords and data that can harnessed for decision-making in selecting project supervisors for students. Machine Learning, an Artificial Intelligence component that learns from data without being explicitly programmed, and Natural Language Processing (NLP) comes in handy in this case for intelligent Decision Support System (DSS). Following the Cross Industry Standard Process for Data Mining (CRISP-DM), preprocessing and processing tasks were executed on extracted data from potential supervisors' Google Scholar publications for clean data and best results before feeding them into the recommendation engine. This research examines a content-based information filtering recommendation system that compares student project proposal data to a pool of possible supervisors' Google Scholar research publications using the Cosine Similarity algorithm. The system utilizes a Machine Learning and Natural Language Processing-powered recommendation system to provide a list of best-match project supervisors. It employs Python-based Django Web Framework's Model-Template-View (MTV) architecture and Cosine Similarity metric in its algorithms. In addition to automating the manual selection process, this efficient and effective recommendation system maintains its competitive edge through its speed of execution, capacity for enhanced intelligence with expanding data, and potential to ultimately improve research performance by leveraging the shared interests of students and supervisors.

CHAPTER 1 – INTRODUCTION

1.1 Background to the Study

A Final-Year student project remains a fundamental academic task that students must accomplish in an educational institution, whether on a postgraduate or undergraduate level, to demonstrate the skills and knowledge acquired during their academic studies. Project supervisors are appointed or chosen for students primarily for supervision and facilitation to get the most out of academic research. Automating the decision-making process in project supervisor selection is a typical example of Decision Support System (DSS) implementation. DSS improves an organization's efficiency and decision-making speed without human bias. A decision support system is essentially an information system that helps a business make decisions that call for judgment, determination, and a series of actions to support the decision-makers but not necessarily to replace them (Maria, Maryam, Bijan, & Masoud, 2018).

The process of assigning academic project supervisors to final-year graduating students in most Nigerian academic institutions is carried out manually without input from students and lecturers (Yahaya, Abubakar, & Muhammad, 2023). Similarly, the pioneer students and lecturers of ACETEL were also caught up in this norm. Therefore, finding a technology solution strategy becomes essential, necessitating this research in applying Artificial Intelligence (AI) to develop a research supervisor recommender system to recommend the best-fit supervisor for students using Machine Learning and Natural Language Processing.

Recommendation Systems are an essential class of Machine Learning that tries to identify the patterns of human behaviour, especially decision-making and use them to predict results or items that are most pertinent to a particular user. In general, recommender systems act as information filtering tools, offering users suitable and personalized content to reduce the effort and time required to search for relevant information online (Roy & Dutta, 2022).

The three main types of recommender systems are content-based recommender systems, collaborative filtering recommender systems, and hybrid recommender systems (Ko, Lee, Park, & Choi, 2022). Popular services like YouTube, Amazon, and Netflix all have recommendation systems that suggest the next video or purchase based on one's browsing history (content-based) or the browsing habits of other users with one's interests (collaborative). Facebook, which suggests people you might know offline, utilizes a recommendation engine to suggest users.

A content-based recommendation system suggests various items comparable in content to the items that particular users are interested in or have previously liked or enjoyed. Collaborative filtering recommendation systems leverage user preferences to tailor a recommendation to a specific user. Here, the measure of user similarity is an indicator. On the other hand, hybrid approaches combine two or more techniques to solve the shortcomings of individual recommender techniques (Deschênes, 2020).

The similarity of the contents or the users who access the content is the basis on which recommender systems operate. Such similarity between two items can be assessed in various

ways. Recommendation systems employ this similarity matrix to suggest the next most similar item to the user (Kilani, Alsarhan, Bsoul, & El-Salhi, 2018).

This research intends to create a recommender system using the Cosine Similarity Matrix to match final-year project students with possible project supervisors based on the students' submitted project topics, abstracts, and keywords. Data from the publications listed on Google Scholar profiles of ACETEL lecturers were extracted and utilized as our foundational dataset. Authors, titles, abstracts, and keywords are among the information extracted from the online publications used in this research.

1.2 Statement of the Problem

- The current system of final-year student project supervisor selection in most typical Nigerian academic settings and, by extension, ACETEL does not take into consideration students' project proposals, lecturers' areas of interest or specializations, and other necessary research-boosting factors before assigning project supervisors to students. Sometimes, students do not even have a basis for their chosen research area, and speculations mostly dominate their motivation. Many students end up with project topics they are either not interested in conducting research on or supervisors not interested in supervising, which ultimately affects productivity.

- By default, ACETEL pioneer students did not have predecessors or seniors who had graduated from the institution from whom to get project recommendation ideas and learn.

- Most students were only familiar with lecturers who had taught them in previous semesters but were unfamiliar with other lecturers in the faculty because they had never had contact with them, neither with their academic publications nor are aware of their specializations.

- In addition, the inefficiency of the manual selection process, which is often not void of human bias, also raises concern for the students' project supervisor selection process.

However, with recent advancements in data science and pervasive computing, recommender systems, which are increasingly being used in large numbers of applications like movies, e-commerce, books, web search, and specialized research resources, can now be tailored to automate the project supervisor selection process. This research seeks to fill these identified gaps by building a content-filtering Machine Learning model of recommender systems to match student project proposals with the most suited potential project supervisors who can provide guidance, mentorship and possible facilitation.

1.2.1 Research Questions

In as much as this research seeks to explore and explain the application of cosine similarity to predict potential project supervisors for graduating students with a content-based technique of recommender systems, it also seeks to answer some salient questions:

- Is Cosine Similarity an effective approach project for project supervisor recommendation system?
- How do you evaluate the accuracy of cosine similarity?

Measures in this research were deployed to transform extracted research publications of lecturers and students' research proposals into vectors and apply similarity measures between these text representations to recommend project supervisor(s) that satisfy the notion of proposed research similarity with past research publications of lecturers. A representative dataset of sixteen lecturers' publications is used to investigate combinations resulting from one thousand one hundred and forty-one (1,137) publication representations and a similarity measurement utilizing cosine similarity. To validate this research question, we were able to establish that cosine similarity, as it were, is an algorithmic metric used in a variety of machine learning algorithms, including K-Nearest Neighbour (KNN) for calculating the distance between neighbours, in recommender systems for recommending similar movies, and textual data for determining the similarity of text in documents. With a statistically accepted baseline range of zero to one (0 to 1), we contrast the outputs of the model (cosine similarity). Distances decrease as similarity increases. When choosing a similarity threshold for texts or documents, a number higher than 0.5 often indicates significant similarities. In the literature review, some of the techniques engaged in the research were noted. Our findings also reveal that Euclidean distance produced fewer encouraging findings than content-based recommendations utilizing a cosine similarity matrix.

1.3 Aim of the Study

The aim is to create a recommender system that recommends project supervisors for students, complementing the institution's current project supervisor selection procedure.

1.4 Specific objectives

These specific objectives serve as action guides to achieve our aim.

1. To build a dataset from scholarly publications of selected lecturers with data extracted from the publications listed on their Google Scholar profiles.
2. To develop a suitable model with a text similarity algorithm that can be integrated into the system.
3. To build an interactive web-based application from the Machine Learning project that provides a user interface for inputting student project proposal data and displaying the resultant Machine Learning/NLP recommended project supervisor.

1.5 Scope of the Study

While the challenge of inefficiency in the manual selection of supervisors for final-year project students persists, automating the decision-making process remains a viable means of matching students with potential supervisors. This research aims to create a recommender system to suggest project supervisors for final-year students to automate the existing selection process with speed, efficiency, and accuracy without human bias.

Due to constraints in data collection and research duration, the scope of coverage of this research is limited to automating the project supervisor selection process of ACETEL's MIS Department. However, it can be broadened to include the ACETEL Faculty and institution. With the availability of big data infrastructure and resources, this academic research work can

also be expanded and diversified into additional purposes that could be implemented in the form of distinct modules integrated into a full-blown robust application.

Recommender systems are basically of three types, i.e., content-based Filtering, collaborative Filtering, and a hybrid of content-based and collaborative. This research is focused on a Content-based Filtering (CBF) method. It is one of the most effective recommender systems based on content correlations. The similarities between items are determined by CBF using item data expressed as attributes (Son & Kim, 2017). Our content type is text-based, which includes the text of lecturers' research keywords, research titles, and research abstracts. Engaging the Cosine Similarity Matrix algorithm, we can measure the distance between inputted student proposals and lecturers' past research work to gauge how closely the sentences are related. The recommender is comparable to other recommender engine methodologies in terms of user profiles, item descriptions, and methods for matching profiles with objects to get the most relevant user suggestion results (Mohamed, Khafagy, & Ibrahim, 2019).

This Machine Learning research incorporates Natural Language Processing and Software Engineering concepts with processes and procedures, including data gathering, data preprocessing, data processing, web application development and recommender engine development. It uses experimental research design as the quantitative approach to predict recommendation results. Our research approach in this study is quantitative, based on a review of relevant literature, empirical findings, and other factors indicative of the fact that our analysis involves data modeling using statistical analysis methods to test relationships between variables (Kamiri & Mariga, 2021).

1.6 Significance of the Study

i. This research work would aid the institution in making more informed and actionable decisions on project supervisor selection.
ii. Changes in project-related matters frequently occur, including project topic, research area, or project supervisor. The recommendation system comes in handy to provide multiple suggested results based on current and historical data.
iii. Students get more enthusiastic when their research area and topic match the supervisor's research interests, specialization or ongoing research work. This could breed improved facilitation by the lecturer. Ultimately, both the student and the supervisor may benefit from the enthusiasm, motivation and productivity.
iv. The recommender system can be extended to gather ACETEL students' projects and research publications, which could function as an Academic Research data repository from which further tech-driven innovations and data analysis can be carried out in the future.
v. Students can depend on reliable data from the Academic Research repository in addition to data sourced from classmates, lecturers and predecessors.
vi. It is a significant contribution to the body of knowledge from which further research can be carried out.
vii. It has the potential to generate revenue for ACETEL under a well-designed business model by transforming it into a technology research hub, serving as a meeting place for students and lecturers.

The platform can be built with the following in mind:

a. A platform for the generation of research topics and ideas.
b. A training/mentoring platform - Many students who are new or used to research concepts could benefit significantly from premium mentorship and training packages on research guidance, writing, and presentation.
c. A platform for collaborative research on project ideas across geographical boundaries.

1.7 Definition of Terms

Terms	Definition
Artificial Intelligence	Artificial intelligence (AI) is the capacity of a computer or robot under computer control to carry out operations typically performed by intelligent beings.
Algorithm	An algorithm is a systematic procedure that generates the response to a request or the solution to a problem in a certain number of steps.
Backend	The backend, or portion of a computer system or program, is usually in charge of storing and processing data and is not immediately accessible by the user.
Corpus	A set of machine-readable genuine texts (including transcripts of spoken data) chosen to be representative of a certain natural language or language variation.
Cosine Similarity	Cosine Similarity is a metric used to ascertain the degree of similarity between two entities regardless of their magnitude.
Data Mining	Data mining refers to the systematic extraction of patterns and useful insights from large collections of data.
Frontend	The frontend is the user interface of a software application or website that encompasses all elements that facilitate user interaction.
Natural Language Processing (NLP)	Natural Language Processing, or NLP, is the area of computer science (more specifically, the area of artificial intelligence, or AI) that tries to make machines understand spoken and written language more like people do.
Structured Query Language (SQL)	Structured Query Language, or SQL, is a standard computer language used to get data out of relational systems, organize it, control it, and change it.
Text Mining	The act of converting unstructured text into a structured format in order to find significant patterns and fresh insights.
Web Application	A web application refers to a kind of software that operates inside a web browser.
Web Framework	A web framework is a software framework specifically intended to facilitate the creation of online applications, including web services, web resources, and web APIs.

1.8 Organization of the Thesis

The Thesis organization is simple, following the sequence and procedure to put our project supervisor recommendation system into practice and assess its effectiveness.

Chapter one will give us a background into the challenge of project supervisor selection and the possible solution. The aim and specific objectives of the research in meeting the identified needs, the scope and significance of the proposed approach are elaborated here.

Chapter two will explore the existing works of literature and research that have been carried out in the field of recommendation systems in the past and their attempts at solving or proffering solutions to the challenge. Attention will be given to Cosine similarity and TF-IDF in this chapter.

The methodologies and industry best practices used to develop the proposed structure for addressing the issue of student supervisor assignment and selection are covered in Chapter 3. Along with other pertinent concepts, this discussion covers the ideas of data science and software engineering. Here, the flow chart and use case diagram of our approach and methodology are discussed. Django web framework and our rationale for such a choice will also be discussed here.

Chapter four will focus on the result, analysis and evaluation of the proposed algorithm. The discussion of the results and its implications.

Chapter five will give a summary of the research work, the conclusion and recommendations for improvements and extension for more advancements.

CHAPTER 2: LITERATURE REVIEW

2.1 Preamble

This chapter briefly peeks into Machine Learning as a branch of Artificial Intelligence, Recommender Systems as a Machine Learning technique and some of the essential elements of Recommender Systems. Importantly, this chapter evaluates relevant published works on Recommender Systems and related works as it applies to student project supervisor recommendations and the summary of reviewed related works.

2.2 Theoretical Framework

This section gives a foundational review of existing theories that serve as a roadmap for developing our arguments in this research. Theoretical explanation is given to explain existing theories in Machine Learning and recommendation systems that support this research, showing its relevance and its foundation in established ideas.

2.2.1 Machine Learning

Machine Learning is the branch of Artificial Intelligence that enables computers to learn from data without being explicitly programmed. Inspired by the human learning process, Machine Learning algorithms learn from data repeatedly and allow computers to discover hidden insights (Sharifani & Amini, 2023). Machine Learning has three subcategories: Supervised, Unsupervised, and Reinforcement Learning. Supervised Learning is characterized by its use of labeled data to train algorithms for accurate prediction. Label in data is that feature used to differentiate one attribute from another. We teach the model, and then it can predict unknown or future instances with that knowledge. We teach the model by training it with data from our labeled dataset. Unsupervised Learning is Machine Learning in which the algorithm trains on the dataset and draws conclusions on the unlabeled data. It derives conclusions from the unlabeled dataset and learns from the data. Instead of controlling the model, we allow it to find information that might not be obvious to the human eye. Reinforcement Learning mimics how people learn from data daily by adapting to changes. It has a self-improving algorithm that adapts to new circumstances and learns from mistakes (Haldorai & Arulmurugan, 2019).

Machine learning has a wide range of important societal applications, including chatbots, face recognition in computer games, signing into our phones, bank loan applications etc. These all employ machine learning methods and algorithms. Common Machine Learning techniques include recommender systems, classification, clustering, association, anomaly detection, dimension reduction, etc. Although Machine Learning algorithms exist in a variety of forms, they all have robust resources at their disposal and a common framework. You may see them as pieces you can combine to create your Machine Learning model.

2.2.2 Recommender Systems as a Machine Learning Technique

One famous instance of Machine Learning is the suggestion (recommendation) systems. A Recommender engine (Recommender System) is a system that predicts what a user may want based on prior searches or purchases. Many industries, including e-commerce (eBay, Alibaba, Jumia, etc.), financial services (investments), and social media platforms (Facebook, Twitter,

Youtube, Instagram, Threads and so on), engage the use of recommendation algorithms for their products and services. Websites and services such as Netflix, Amazon, and YouTube use these algorithms to recommend videos, movies, and TV series to viewers. It is similar to how friends recommend TV series to one another based on their familiarity with show genres.

Since recommender engines have become more prevalent in recent years, there has been an increase in the number of algorithms employed in recommender systems to provide customers with individualized recommendations, improved user satisfaction and experience. Artificial Intelligence now makes recommendations of better quality than those made using traditional approaches (Zhang, Lu, & Jin, 2020). This is where Machine Learning comes in since it serves as a strong basis for developing and upgrading many of these recommender engines.

2.2.3 What are Recommender Systems?

The explosive growth of available information and rapid increase in Internet users and e-services has created an imminent difficulty of information overload, which impedes quick access to contents of interest on the Internet and frequently results in more complicated decision-making. Although information retrieval systems such as Google, Bing, Yahoo and Yandex have primarily overcome this challenge, prioritizing and personalizing information (where a system matches accessible content to a user's interests and preferences) were lacking. This development has resulted in a greater need for recommender systems than ever (Zhang, Lu, & Jin, 2020). Recommender systems are techniques and tools that make suggestions for items most likely to interest a specific user. They provide a potent way to assist users in sorting through a huge selection of items to find those that are most likely to be picked. They employ algorithms that take into consideration the user's browsing habits, searches, purchases, and preferences, among other factors. Recommender Systems help people navigate the enormous number of options available on the Internet by employing data from several sources to predict a user's preferences for items of interest. If you purchase an item from a website, other goods may be suggested depending on the content item's parameters. For instance, the algorithm may suggest different books written by the same authors or books with similar themes to the ones you recently purchased (Mohamed, Khafagy, & Ibrahim, 2019).

2.2.4 Recommender Systems Utility Matrix

The two main components of recommender systems are users and items, with each user assigning a rating (or preference value) to an item (or product). In general, implicit or explicit approaches are used to acquire user ratings. Through the user's engagement with the items, implicit user ratings are inadvertently gathered from the user. Contrarily, the user provides explicit ratings directly by selecting a value from a restricted range of point rates or indicated interval values. The rating can be expressed in a standard form (Strongly agree, agree, neither agree nor disagree, disagree, strongly disagree), numerically (five-point scale, from 1 to 5), or by a binary method (I like/do not like) or unary (information present or absent). For instance, a website may gather implicit ratings for various items based on clickstream data, user engagement metrics, and other factors. Most recommender systems employ both explicit and implicit techniques to collect user ratings. The user feedback or ratings are placed in a user-item matrix known as the utility matrix, as shown in Table 2.1. The utility matrix frequently has multiple missing values. The major challenge of recommender systems primarily concerns locating missing values in the utility matrix.

Table 2.1: Utility Matrix

	Item 1	Item 2	Item 3	Item 4
User 1	7	3	-	2
User 2	5	-	-	3
User 3	-	2	3	5
User 4	6	-	-	-

This process is frequently challenging since the initial matrix is typically sparse because consumers rate only a few items. It is also worth emphasizing that we are only interested in items with high user ratings because only such items will be recommended to users. The performance of a recommender system is highly dependent on the type of algorithm utilized and the nature of the data source, which can be textual, visual, contextual, or any combination of these (Roy & Dutta, 2022).

2.2.5 Core Element of Recommender Systems

The fundamental recommendation question is to check if a user, $u \in U$ will be interested in item $i \in I$, for U and I as the domain of users and items, respectively. The most common ways to answer such questions are:

1. To find out the set of items that u liked previously and then find the similarity between them and i.
2. To find out people who like i and try to compute their similarities with u.

In the above two cases, the similarity values are used to measure the degrees to which u is interested in i (Salau, et al., 2022). In a nutshell, recommender systems are created to determine whether an item is worth being recommended and then measure its utility. The function to define the utility of a specific item $i \in I$, to a user $u \in U$ is:

$$f : U \times I \rightarrow D.$$

The final list of recommendations, D, contains a selection of items that have been ranked based on how useful all the items are that the user has not yet consumed. User ratings are used to illustrate an item's usability. To select the best item for the user, recommender systems maximize the utility function. Utility prediction of items for a specific user changes depending on the recommendation algorithm (Zhang, Lu, & Jin, 2020).

2.2.6 Classification of Recommender Systems

Users, items (services or products that the system wishes to promote), and transactions, which reflect interactions between the system and the user, are the entities with which a recommender operates. The rating, or a user's assessment of a certain item, represents the most prevalent type of transaction. Effective Recommender Systems are distinguished from ineffective ones by their capacity to produce reliable rating projections, making this aspect crucial when assessing

the methodologies (Casillo, et al., 2023). Recommender systems use several forms of Filtering and are broadly categorized into three types: Collaborative, Content-based, and Hybrid recommender systems.

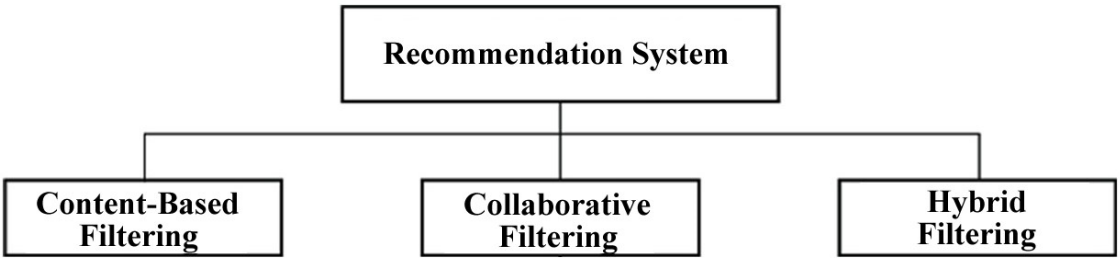

Figure 2.1: Classification of Recommendation Systems

2.2.7 Content-based Recommender Systems

Content-based recommender systems focus on suggesting items or products comparable to those that have previously ignited the user's interest. This method makes use of a certain item's attributes and metadata to propose more items with similar features.

As the name implies, content-based recommender systems predict an item's utility based on a user's profile by analyzing the item's description. To start with, several item attributes are drawn from documents or descriptions. For instance, the attributes of a movie film can be represented by its genre, director, writer, actors, plot, etc. These characteristics can be discovered directly from unstructured data, such as news or articles, or from structured data, like a table. The vector space model with term frequency-inverse document frequency weighting, a keyword-based model, is one of the most often used retrieval methods in content-based recommender systems. A user's preferences are profiled by content-based recommender systems using items from their consumption history. Typical profile information includes details on prior preferences like past likes and dislikes of the individual. As a result, the profiling process may be viewed as a conventional binary classification issue, which has been extensively researched in machine learning and data mining. In this stage, traditional techniques like Naive Bayes, closest neighbour algorithms, and decision trees are applied (Falconnet, et al., 2023). After creating the user's profile, the system analyzes the item's attributes with the profile and identifies the most suitable elements to use as the basis for a suggestion list. A content-based recommender system's recommendation process is a filtering and matching operation between the user profile and the item representation based on the features obtained in the first two phases. The recommendation's relevance evaluation is based on the correctness of the item's representation and the user's profile since the end result is to push forward the matching items and delete those the user does not like (Roy & Dutta, 2022).

There are several benefits the content-based recommender system offers, including.

1. A content-based recommendation is first user independent because it is based on item representation. Therefore, the data sparsity issue does not affect this type of system.
2. In order to address the issue of new item cold-start, content-based recommender systems can make recommendations for new products to users.

3. Content-based recommender systems can describe the recommendation outcome in detail. In comparison to other techniques, this sort of system's transparency has several advantages in practical applications.

However, there are a few drawbacks to content-based recommender systems.

1. Although overcoming the new item problem, these systems still face the new user problem since the accuracy of the recommendation result is significantly impacted by the lack of user profile information.
2. In addition, content-based techniques usually select similar items for users as recommendations, which overspecializes the suggestion. Because most users like to learn about novel and appealing items rather than being restricted to those that are comparable to those they have already used, these sorts of suggestion lists frequently lead users to get bored.
3. Another problem is that items aren't always simple to express in the precise way that content-based recommender systems demand. Therefore, rather than recommending music or pictures, this type of algorithm is more suited for promoting articles or news items (Zhang, Lu, & Jin, 2020).

2.2.8 Collaborative filtering-based recommender systems

Collaborative Filtering-based (CF) recommender systems infer the utility of an item based on other users' appraisals as opposed to content-based recommender systems, which are independent of other users but reliant on a user's personal history data. This technique got implemented in the industry world more than 20 years ago (Deschênes, 2020) and has been the subject of much academic research. Collaborative Filtering continues to be the most often utilized technique in recommender systems today (Mohamed, Khafagy, & Ibrahim, 2019). The fundamental premise of the CF approach is that people who have similar interests would seek out similar items. As a result, a system that employs Collaborative Filtering relies on data provided by users who share the same preferences as the given user.

Collaborative Filtering can be implemented using two approaches to generate recommendations based on the user's prior interactions: memory-based approach and the model-based approach. In a typical collaborative filtering situation, there exists a list of m users, denoted by U = {u1, u2, .., um}, and a list of n items, denoted by I = {i1, i2, .., in} as well as the item's opinion, also known as rating. The memory-based method predicts ratings for an active user by looking at the most similar users, whereas the model-based approach builds a model from the user/item interaction to predict ratings. The basic idea of collaborative Filtering is that collaborative Filtering make predictions based on the opinions of users with similar characteristics. Memory-based collaborative Filtering predicts using the entire user-item dataset to generate a recommendation system. It approximates users or items using statistical approaches. Pearson Correlation, Cosine Similarity, and Euclidean Distance are a few examples of these approaches. However, model-based collaborative Filtering uses the data in the database to develop a model in an attempt to learn their preferences and subsequently make predictions. Models can be created using Machine Learning techniques like regression, clustering, classification, and so (Karavidaj, 2020). Unfortunately, the scope of our research is

limited to content-based recommender systems as it applies to project supervisor recommender systems.

2.2.9 Hybrid Recommender Systems

In order to enhance the system's capacity for prediction, hybrid recommender systems incorporate two or more techniques. A single model can be made to incorporate the features of the selected method or the techniques can be employed individually before being integrated (Casillo, et al., 2023).

2.2.10 The Limits of Recommender Systems

The primary issues that recommender systems face include but not limited to:

1. Scalability: the system's ability to handle additional data that is made available.
2. Sparsity (small number of known ratings) should not have an impact on the accuracy of the predictions.
3. Cold Start: The difficulties of recommender systems in predicting new users or items.

The benefits and drawbacks of the above-mentioned recommendation approaches are listed in Table 2.2 (Casillo, et al., 2023).

Table 2.2: Advantages and Limitations of Recommendation Techniques

Recommendation Techniques		Advantages	Limitations
Content-based RS		Easiness in suggesting new items Easiness of implementation	Cold Start (new user) Diversity
Collaborative Filtering RS	Memory-Based	Easiness of data updating Easiness of implementation	Cold start (new user /new item) Sparsity Scalability
	Model-Based	Compares well with sparsity and scalability The resulting performance is better	Cold start (new user /new item) Loss of information because of the use of factorization techniques

Hybrid RS		Provides better suggestions Overcomes the limitations of individual techniques	Complexity Model development cost

2.2.11 Distance Metrics in Machine Learning

The distance between two data points is used by several supervised and unsupervised machine learning models, including K-NN and K-Means, to predict the outcome. As a result, the metric we employ to calculate distances is crucial in these models. Some of the common distance metrics employed in machine learning models include the Euclidean distance, the Minkowski distance, the Manhattan distance, the Hamming distance and the Cosine distance. When determining the distance between two data points in a grid-like pattern, we utilize the Manhattan distance, sometimes referred to as city block distance or taxicab geometry. The Euclidean distance is the distance that exists in a plane of a pair of data points along a straight line. The Hamming distance is a comparison statistic for two binary data strings. The cosine distance and cosine similarity metrics are mostly used to identify similarities between two data points.

2.2.12 Cosine Similarity and Cosine Distance

The cosine similarity, or degree of similarity, reduces as the cosine distance between the data points rises, and vice versa. As a result, points that are near to one another are more similar than those that are far apart. Cos θ represents the cosine similarity, while the cosine distance is 1-Cos θ. In order to provide users with future recommendations, recommendation systems employ the cosine metric of cosine distance and cosine similarity.

For instance, if two data points are separated by 90 degrees, as in Figure 2.2 and you know that Cos 90 = 0, then you may use this to your advantage. The cosine distance between the two points is, therefore, 1 - Cos 90 = 1, which indicates that the two data points are not similar.

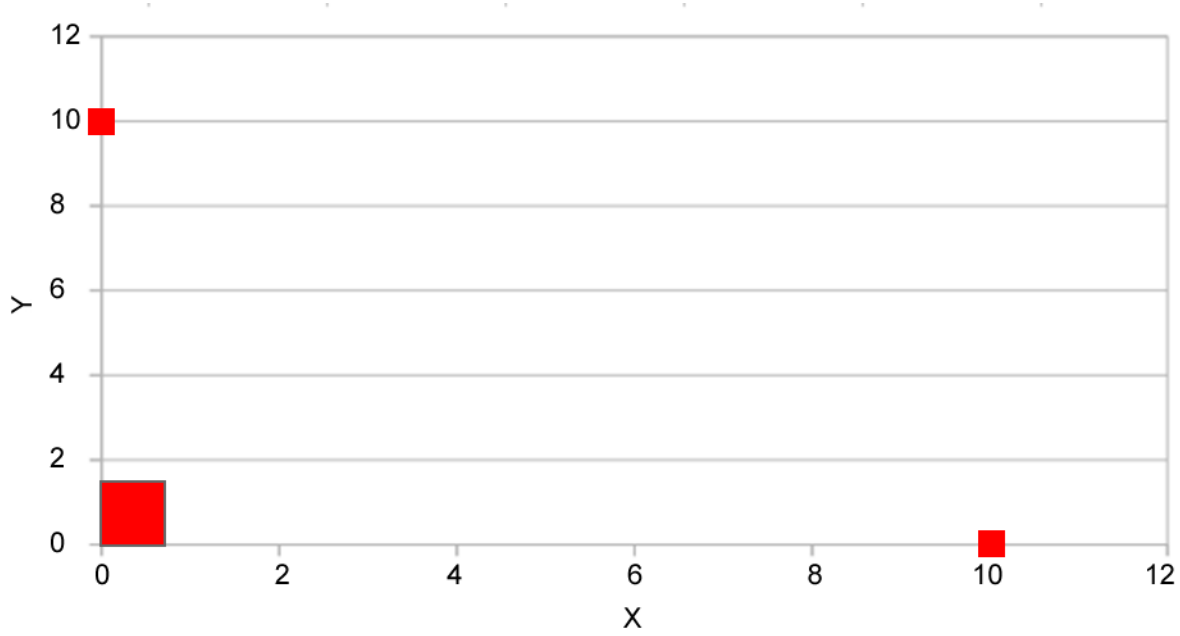

Figure 2.2: Two Data Points separated by Ninety Degrees

As seen in Figure 2.3, another example would be if the angle between the two points was 0 degrees. In this case, the cosine similarity would be 1 (Cos 0 = 1), while the cosine distance would be 1 - Cos 0 = 0. The two points are therefore interpreted to be 100% similar.

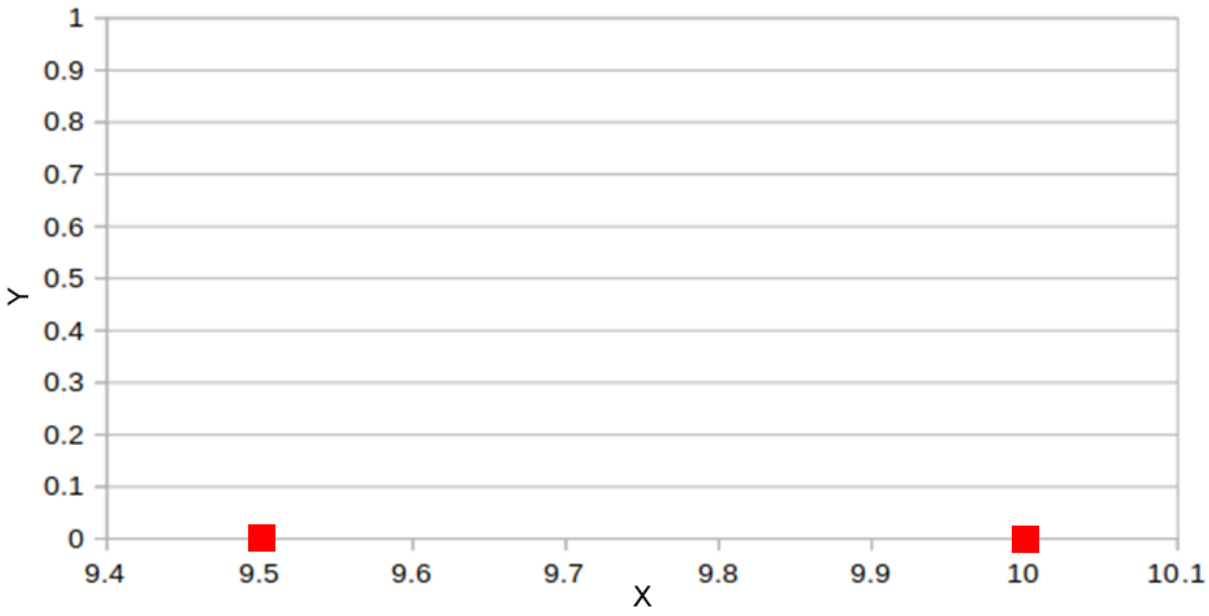

Figure 2.3: Two Data Points separated by Zero Degrees

Let's say the value of θ is 60 degrees as shown in Figure 2.4. Using the cosine similarity formula, this means that the cosine distance is 1 - 0.5 = 0.5. Consequently, there is a 50% similarity between the data points.

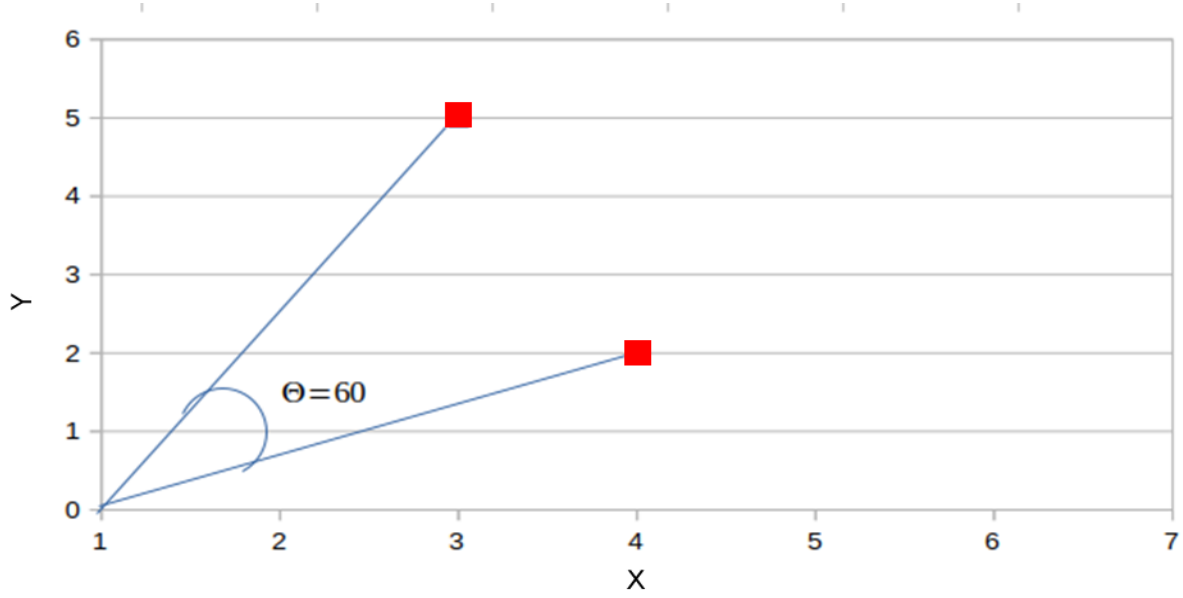

Figure 2.4: Two Data Points separated by Sixty Degrees

2.2.13 Cosine Similarity – Text Similarity Metric

In order to determine how closely two text documents are similar to one another in terms of context or meaning, text similarity is utilized. There are several text similarity measures, including Jaccard Similarity, Cosine Similarity, and Euclidean Distance. Each of these metrics has a unique specification that measures how similar two queries are to one another. In our study, the cosine similarity metric is employed. Cosine similarity is one of the metrics used in natural language processing to compare the text similarity of two documents, regardless of their size. Vector representations of words are used. In n-dimensional vector space, text documents are represented. Cosine similarity is a mathematical metric that calculates the cosine of the angle between two n-dimensional vectors projected in a multi-dimensional environment. The-Cosine similarity between two papers will be between 0 and 1. If the Cosine similarity score is 1, it signifies that the orientation of two vectors is the same. The closer the value is to 0, the less similar the two papers are.

Cosine similarity between two non-zero vectors A and B is expressed mathematically as:

$$\text{Similarity} = \cos\theta = \frac{A \cdot B}{|A||B|} = \frac{\sum_{i=1}^{n} A_i \times B_i}{\sqrt{\sum_{i=1}^{n} (A_i)^2} \times \sqrt{\sum_{i=1}^{n} (B_i)^2}}$$

Where:

A = Vector A

B = Vector B

A • B = dot product between vector A and vector B

|A| = vector length A and |B| = vector length B

|A||B| = cross product between |A| and |B|

2.3 Review of Relevant Literature

Initially, Recommender systems were applied in e-commerce to address the information overload brought on by Web 2.0. Soon after, they rapidly expanded to personalizing e-government, e-business, e-tourism, and e-learning (Zhang, Lu, & Jin, 2020). Over the years,

they have become an indispensable feature of educational and training websites, with the likes of Coursera, Udemy, etc., to recommend learning resources and online courses that might interest a specific user. Given the digitization of education and the massive increase in online learning resources via massive open online courses and learning management systems, recommender systems research has been advancing rapidly. These systems today are being used in a growing number of specialized fields, notably in the domain of Technology-enhanced Learning (TEL) (Deschênes, 2020).

Recent literature evaluations on recommender systems in education have taken into account quite a number of methodologies and approaches. In one of such literature, ontology-based recommenders were examined. The research was carried out in 2018 by Tarus, Niu, and Mustafa, where they acknowledged that ontology-based recommendations paired with other recommendation techniques are frequently used to suggest learning resources, but they didn't thoroughly investigate techniques that may be combined with this recommendation (Tarus, Niu, & Mustafa, 2018).

Ontology is a method of modeling learners and learning materials, among other things, to aid in the retrieval of details. This results in more relevant content for learners. Ontologies provide the advantages of reusability, reasoning ability, and support for inference procedures, which aid in providing better recommendations (George & Lal, 2019).
Another study by Charbel Obeid, Inaya Lahoud, Hicham El Khoury, and Pierre-Antoine Champin on ontology-based recommender systems in higher education reveals a method for creating ontology-based recommender systems improved with machine learning techniques to guide students in higher education. The recommender system serves as a tool for evaluating students' interests, skills, and areas of occupational strength and weakness (Obeid, Lahoud, Khoury, & Champin, 2018).

Despite all the benefits that ontology offers, the names given to the ontology model's different classes, properties, and individuals are a challenge. Another issue while developing ontologies is the inappropriate usage of classes and persons (George & Lal, 2019).

A unique Learning Companion Application with adaptive learning technologies that optimize Technology Enhanced Learning (TEL) offerings to match the individual learner's needs was presented in research titled Time-Dependent Recommender Systems for the Prediction of Appropriate Learning Objects (Krauß, 2018). The application provides learning recommendations to help you choose more efficient and effective content. It was determined that standard recommender systems could not be easily transferred to TEL because course item recommendations followed a specific educational paradigm. The unique characteristics of this paradigm are first examined and then considered while developing new algorithms. A reference architecture for such an adaptive learning environment is created by a collection of open standards and specifications, allowing for extensive compatibility of a Recommender System with other technical elements. Based on the realized architecture, activity data were collected from students via online course materials - the courses include face-to-face lectures supplemented by digital representations of the delivered contents, blended learning environments, and online-only courses. This research also suggests that an educational

recommender system should not be examined using typical evaluation frameworks such as n-fold cross-validation. As a result, a time-dependent assessment framework is defined to examine the precision of Top-N learning suggestions at different periods.

2.4 Review of Related Works

The application of computational methods to analyze document similarity in specialized industry domains has been a research subject over the years with practical applications in different industries, including legal, academic, news publishing, search engines, etc. However, innovations in Text Mining (TM) and Natural Language Processing (NLP) in the second half of the 2010s, such as Text Embeddings based on Neural Networks (NNs), gave this area new possibilities and a boost (Silva et al., 2022). The document format or representation, the text embedding (also known as text vectorization), and the similarity measurement technique are the three primary parts that are often varied when investigating textual similarity. Typically, the similarity measurement technique makes use of a vector distance metric (Hugo Mentzingen et al., 2023).

In the white paper, A Survey of Numerous Text Similarity Approach Dasgupta (2023), several approaches focusing on various text similarity techniques used in everyday life use cases to calculate the similarity between contents were surveyed. Among them are Euclidean distance, cosine similarity, Jaccard Distance, Manhattan distance etc. It was pointed out that methods for resolving text similarity use cases have been available for a while, but their key shortcomings include the loss of dependence information, the inability to recall lengthy conversations, inflating gradient issues, etc. Modern deep learning models pay attention to both nearby and far-off words, which improves their capacity for rigorous learning (Dasgupta et al., 2023).

The findings of using several strategies for semantic text similarity measures in documents used for safety-critical systems are presented by Qurashi (2020) in Methods for Semantic Text Similarity Analysis. It was discovered that documents with unstructured data and different formats needed to be preprocessed and cleaned before the set of Natural Language Processing toolkits, and Jaccard and Cosine similarity metrics were applied. The research aimed to measure the degree of semantic equivalence of multi-word sentences for rules and procedures contained in some documents. The outcomes show that by utilizing Natural Language Processing and similarity measurement approaches, it is possible to automate the process of finding identical rules and procedures and gauge the similarity of various safety-critical documents (Qurashi et al., 2020).

Several studies have been conducted on recommender systems as regards final year projects, the graduating students, in some cases predicting project topics, some recommending lecturers, research materials, acting as repositories, etc.

In their research, Arumi (2019) developed an Analytical Hierarchy Process (AHP)-based decision support system for selecting thesis supervisors. It takes into account the lecturer's area of expertise in accordance with the criteria for selecting lecturers, lectured subjects, conformity of thesis title topics, and duration of guidance. Data is extracted from Google Scholar, the decision letter for each semester's instruction, and the submission of student thesis proposals. The weighing of the criteria according to the AHP method shows that the title of the proposed

thesis is the factor that has the most impact on the selection of the lecturer as thesis supervisor, followed by the lecturer's research interests and the lecture they delivered, according to the eigenvector value's outcome (Arumi et al., 2019).

Fiarni et al. (2021) use a Machine Learning technique to study and construct an algorithm that recommends final project topics based on a student's interests, skills, and assigned supervisor. As a feature selection component, this research also built a framework to map academic qualities. In order to recommend topics based on similarities between student profiles and those topics represented by lists of keywords, a recommender system based on the cosine similarity algorithm was created. Performance is assessed by contrasting the recommended system's suggestions with the actual topic selected by the students, with a high accuracy score of 71.43% (Fiarni et al., 2021).

In another research, Kazakovtsev (2020) developed a recommender system for selecting an academic supervisor based on evaluating the similarity of student interests and the scientific accomplishments of the potential mentor from the university faculty. The recommender system used an unconventional method to calculate similarity without using co-authorship networks instead of Scopus quality metrics. The cumulative distribution function of the logarithm of the weighted impacts of academics in the field was applied as a normalizing technique. Due to the difficulties of comparing the received recommendations with the data from previous years, it evaluated several similarity measures. After that, clustering was performed to assess their suitability and the system's quality (Kazakovtsev et al.).

A web-based system using the TF-IDF word weighting and cosine similarity algorithm was developed by Rismanto et al. (2020) in the research, Research Supervisor Recommendation System Based on Topic Conformity. With the TF-IDF approach, one could determine the importance of a word's connection to the document. Using keywords from a document as a measure, the cosine similarity is used to determine how similar two items expressed in two vectors are to one another. The final assignment adviser who has done a study on the subject of the student's final assignment is recommended to students based on the findings of the advisor recommendation system. By comparing system suggestions with the real assigned supervisor in 20 tests, the accuracy of comparing the outcomes with the actual data averaged 75% (Rismanto et al.).

Wijanto (2020) creates a thesis supervisor recommender system with representational content and retrieval of information. When a student thesis proposal is accepted, the system responds with a list of potential supervisors in decreasing order based on the relevance of the prospective supervisor's academic publications to the proposal. Similarly, the profiles of supervisors are drawn from previous scholarly papers. The research employs the information retrieval idea with cosine similarity and a vector space model for scalability. Findings show that grouping supervisor candidates based on their broad experience is beneficial in matching a possible supervisor with a student, according to the accuracy and Mean Average Precision (MAP). Lowercasing has been shown to improve accuracy. The MAP benefits from considering the top ten most common words in each lecturer's profile. (Wijanto et al.).

Madeira (2021) analyzes a recommender system that enables one to select an academic supervisor based on their academic genealogy in their research utilizing the Nearest Centroid model. Application of metadata from several theses and dissertations was used to carry out the recommendation. The acquired findings demonstrated a high degree of suggestion precision, supporting the claim made by Madeira et al. that the suggested approach is a helpful tool for graduate students.

In his research article, Hasan (2019) employed the K-Nearest Neighbour method with cosine similarity to locate supervisors based on individual preferences. The collaborative filtering algorithm was employed by the recommender system. According to the user's choices or areas of interest in the research, it uses multiple filtering factors to identify relevant supervisors. The model (Hasan) attained a classification accuracy of 76.0% for the expected outcomes.

2.5 Summary of Reviewed Related Works

The review of these related academic works in the preceding section 2.4 shows that significant research and advances have been made in the past, yielding knowledge that one can build on to create a unique research supervisor Recommender System. This research showcases an effective way of matching a potential supervisor with a research student using text vectorizations, cosine similarity method and displaying the top-recommended result on a web-based interface. It intends to fill the automation gap in the supervisor selection process with high-accuracy recommendations and complement the decision support system.

CHAPTER 3: RESEARCH METHODOLOGY

3.1 Preamble

Research methodology is an essential consideration before beginning a research endeavour, as it outlines the specific phases of structured/systematic procedures or techniques used to identify, select, process, and analyze information about the topic of discussion. The research methodology utilized in this study is depicted in Figure 3.1.

3.2 Problem Formulation

This phase involves the identification and conceptualization of the problem based on research findings. After recognizing the challenges related to the inefficiency of the manual project supervisor selection process, which hampers productivity and motivation among students and their supervisors, it is crucial to explore potential solutions and define the scope of the problem for further investigation.

3.3 Proposed Solution, Technique, Model/Framework

In this research, the Cross-Industry Standard Process for Data Mining (CRISP-DM) is used, which is a common practice in data mining tasks, as is often seen in the field of Machine Learning research. The CRISP-DM framework is a well-established and universally applicable standard for efficiently structuring data mining projects.

Figure 3.1: Cross-Industry Standard Process for Data Mining (CRISP-DM)

The paradigm in question has been widely used in several industrial projects and has consistently shown its efficacy in practical implementation. (Schröer, Kruse, & Gómez, 2021) The process has six iterative steps, beginning with business understanding to deployment of the solution.

The process of CRISP-DM is classified into:

1. Business Understanding
2. Data Understanding
3. Data Preparation
4. Modeling
5. Evaluation
6. Deployment

Table 3.1 provides a concise overview of the primary concept, activities, and outcomes associated with each phase.

Table 3.1: CRISP-DM Process Model Descriptions

S/N	Phase	Short Description
1	Business Understanding	The business or project situation is evaluated to determine the available and necessary resources. Determining the data mining objective is one of the most crucial aspects of this phase. The data mining type (e.g., classification, clustering, association) and performance criteria (e.g., precision) is explained first. This phase is mandatory and foundational because it forms the premise for the project plan.
2	Data understanding	In this phase, collecting data from data sources, investigating and describing it, and assessing its quality are essential duties. To make it more tangible, statistical analysis are performed; their attributes and their collations are determined in order to describe

		the data. Tableau and Excel comes in handy here as among the tools being utilized for data understanding, so it makes ideal sense to import the data into these programs. If you acquire multiple data sources, you must consider how and when these will be integrated.
3	Data preparation	The process of data selection involves the establishment of specific criteria for inclusion and exclusion. The issue of poor data quality may be effectively addressed via the process of data cleansing. The construction of derived characteristics is contingent upon the model used, as established in the first step. Various approaches may be used for each of these processes, and the choice of method is contingent upon the specific model being used.
4	Modeling	The data modelling step include the process of choosing the appropriate modelling approach or technique, constructing the test case, and developing the model. Various data mining approaches may be used. The selection often hinges upon the specific business issue at hand and the available data. Of more significance is the elucidation of the rationale behind the selection. In order to construct the model, it is necessary to establish specified parameters. In order to analyze the model, it is advisable to test it against predetermined assessment criteria and thereafter choose the most suitable ones.
5	Evaluation	During the evaluation phase, the obtained outcomes are compared and assessed in relation to the predetermined business or project goals. Consequently, it is necessary to analyze the findings and establish further courses of action. Another aspect to consider is the need for a comprehensive evaluation of the process.
6	Deployment	The deliverable in question has the potential to take the form of either a comprehensive report or a software module. The deployment phase includes the activities of deployment planning, monitoring, maintenance and final report.

There is no restriction on how the CRISP-DM may operate; it can alternate between many stages. The outer circle denotes the framework's cyclic qualities, and the arrows indicate that the requirements between phases are crucial to each other. CRISP-DM, as the outer circle graphic illustrates, is not a one-time procedure in and of itself. Every procedure is a fresh opportunity for learning, and it may raise more business issues as well as teach us new things.

Reduced costs and time are two advantages of adopting standard process models for data mining, such as the de facto and most widely used Cross-Industry-Standard-Process model for Data Mining (CRISP-DM). Standard models also reduce the amount of information needed and help with knowledge transfer and best practice reuse. (Ayele, 2020)

3.4 Tools Used in the Implementation

A variety of tools and techniques were utilized during the research's implementation, and they are detailed in the sections that follow.

3.4.1 Functional and Non-functional Requirements

Functional and non-functional requirements are essential for a product to fulfil the requirements of stakeholders and the business. However, it is evident from the name that they prioritize distinct aspects.

3.4.1.1 Functional Requirement

Features and functionalities of the application are defined by the functional requirements. Some of the essential functional requirements of the project supervisor recommender system include:

1. The system should be able to display project supervisor recommendations
2. The system should be able to display information regarding lecturer(s).
3. The system should be able to display information regarding a lecturer's previous research submissions.
4. The system should be able to execute the cosine similarity method for calculating document similarity.
5. The system should be able to accept input from users to search against lecturers' research dataset
6. The system should be able to get input from the Admin to record lecturers' details and their past publications into the database.

3.4.1.1 Non-functional Requirements

1. Speed
2. Security
3. Reliability
4. Data Integrity
5. Usability

3.4.2 Resource Requirements

Resources used in this Research are categorized into the following: Data, Cloud, Hardware, and Software.

3.4.2.1 Data Resources

The main subject of this research work is data (research data). It also acts as the foundation for the analytics and visualizations of this project. A representative dataset of eighteen lecturers' publications is used to investigate combinations resulting from one thousand one hundred and thirty-seven (1,137) publication representations, which were extracted online from lecturers' Google Scholar publications and saved as spreadsheets. For accessible data collection, cleaning and manipulation, the spreadsheet was also synced in the cloud.

3.4.2.2 Cloud Resources

Machine learning experiments typically commence by conducting data analysis on a computer, often without requiring substantial computational resources. Over time, individuals may increasingly require additional resources beyond what their local CPU can provide, which is made possible by the advent of cloud computing. The data collection process involved synchronizing data in the cloud using Google Sheets for the purpose of conducting experiments. Furthermore, using cloud architecture for certain machine learning pipeline activities during the model-building process was aimed at enhancing accuracy. This approach allows access to a centralized resource, enabling the utilization of a developed system. Tableau is a cloud-based service utilized for data analytics in this research. Tableau has the potential to enhance our ability to explore, manage, and derive insights at a faster pace.

3.4.2.3 Minimum Hardware Requirements

The minimum hardware requirements refer to the computer's physical features required to implement the Recommendation System. The features are as follows:

1. Processor: at least Intel Pentium Dual-Core
2. Memory: 4 GB RAM

3. Disk space: 250 GB HDD

3.4.2.4 Software

1. Python 3.10
2. Django Web Framework
3. Visual Studio Code
4. PIP
5. Included Library packages: NumPy, SciPy, Scikitlearn, Pandas, Matplotlib
6. Windows 10 Operating system, MAC.
7. Chrome, Edge and Mozilla Firefox browser

3.5 Approach and Technique(s) for the Proposed Solution

All system components and process flow are explained in the architectural diagram. It overviews the process and helps distribute modules to the group. The architectural diagram shows its organization. Process behaviour may be predicted from the developer's architectural diagram. This section briefly describes our proposed system's modules. (Muthurasu, Rengaraj, & Mohan, 2019)

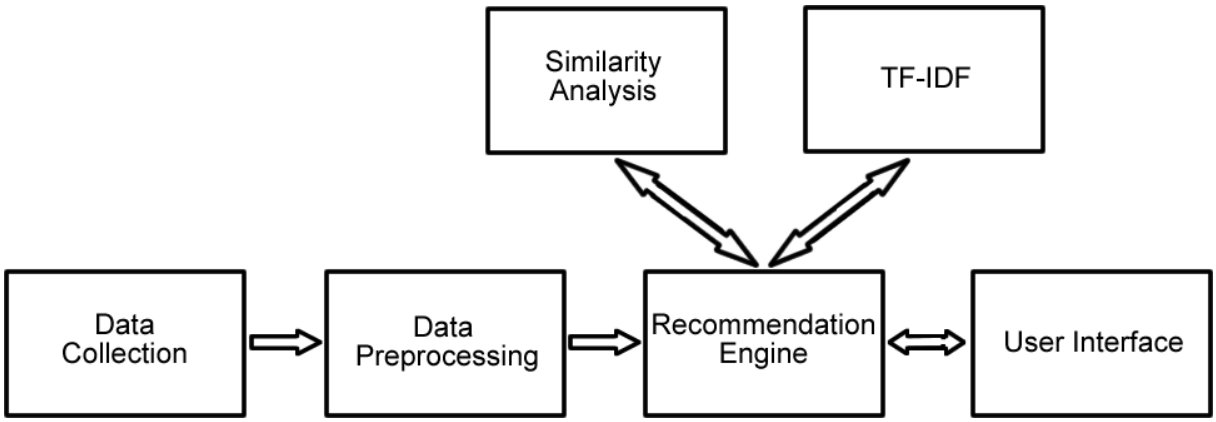

Figure 3.2: Architecture Diagram

3.5.1 Data Collection

Data collection refers to the systematic process of gathering data that is relevant to our specific requirements. The data required for our project's Supervisor recommendation system is textual data. The first dataset contains brief bios of ACETEL's MIS Department lecturers. The data is presented in a spreadsheet format. Table 3.2 shows the Supervisors bio data attributes.

Table 3.2: Supervisors Bio Data Attributes

Number	Attributes	Information
1	picture_link	Supervisor's Picture
2	Name	Supervisor's Name
3	Gender	Supervisor's Gender
4	Email	Supervisor's Email
5	phone	Supervisor's Phone

The second dataset consists of the research publications of the same ACETEL lecturers stated in the first dataset. This data was obtained by sourcing and web-scraping information from each

lecturer/facilitator's Google Scholar profiles. The data attributes include each publication's author name, title, abstract, and keywords. The necessary data was extracted for each lecturer by parsing web pages in HTML format and extracting data from PDF documents. The data was inputted in the form of a CSV file and subsequently parsed during the data processing phase. A total of one thousand one hundred and thirty-seven (1,137) rows of data were extracted, each containing the attributes listed in Table 3.2.

Table 3.3: Supervisors publication data attributes

3.5.2 Data Preprocessing

The first stages in every recommendation system start with data preprocessing.

Due to an unintentional inclusion of HTML, the retrieved supervisors' publications data remained in their unprocessed state. There were both alphabetic and numeric characters, as well as blank rows. Thus, the raw data was subjected to data preprocessing in order to enhance the data format and remove interference, data inconsistencies, and noise.

The following are some of the data preparation procedures that were carried out.

1. Tokenization
2. Case folding
3. Punctuation removal
4. Stop word removal
5. Word vectorization

Prior to using the data as a vector for proximity and similarity measurement, it was necessary to perform noise removal. In addition, the data have to go through the process of tokenization. The data, which is presented in lengthy phrases, will be segmented into individual words or tokens. Subsequently, after the data has been transformed into a token, it will undergo case

folding and punctuation removal, followed by the application of the stopword procedure. Commonly occurring terms in the dataset, which are included in the stoplist, must be eliminated. Stoplists are compilations of words, also referred to as stopwords, that are excluded from being indexed in an information retrieval system and/or are not permitted for use as query terms. Stoplists may be categorized as either general or domain-specific, and it is important to note that they are peculiar to a particular language. As an example, the terms "and," "are," "as," "but," "by," "for," "if," "in," and so on. (kalaivani & Marivendan, 2021)

Once the data has undergone the procedures leading to its transformation into a token, the subsequent stage involves the conversion of the data into a vector. This conversion is achieved by the use of the TF-IDF approach, using an n-gram range spanning from one to two words. An n-gram refers to a consecutive sequence of n elements extracted from a given text, often used in the fields of linguistics and computational probability. The use of N-grams enables the estimation of the likelihood of the subsequent word, hence facilitating comprehension of the semantic context within a given text. The fundamental principle of this approach is the computation of TF and IDF values for each term in relation to every document. (Falah & Suryawan, 2022)
It is essential to carry out this procedure to get clean data before its utilization in the recommendation algorithm.

3.5.3 Data Processing (Recommendation Engine)

In this study, the similarity between the lecturer's research and the proposal provided by students is calculated by comparing the title, abstract, and keywords of potential supervisors' research with those of the student-submitted proposals. Two important techniques will be discussed here to help us achieve the recommendation goal. They include TF-IDF and Cosine Similarity.

3.5.3.1 TF-IDF (Term Frequency-Inverse Document Frequency)

The TF-IDF (term frequency-inverse document frequency) is a statistical metric used to assess the significance of a word inside a given text in a set of documents. This process is achieved by multiplying two metrics: the term frequency, which measures the number of occurrences of a word inside a specific document, and the inverse document frequency, which quantifies the rarity of the phrase over a collection of documents. (Jiang, et al., 2021) The technology has several applications, with particular significance in the realm of automated text analysis. It proves very advantageous in evaluating word scores inside machine learning algorithms used in the Natural Language Processing (NLP) field.

The TF-IDF approach is a widely used technique in the field of information retrieval for determining the significance of individual words by assigning weights to them. The TF-IDF technique was used to identify the most significant terms in the title and abstract of the student's study. These words will be afterwards compared to a database of potential research titles and abstracts using the cosine similarity approach.

The process of word weighting plays a significant role in determining the level of similarity between a document and a query. The weight calculation method presented here combines two

key concepts: the frequency of occurrence of a word within a specific document and the inverse frequency of the document containing the word (Fei & Li, 2022). Several factors are crucial in determining word weighting. These include:

1. **Term Frequency (TF)**

   Term Frequency (TF) refers to a numerical representation that indicates the frequency of a term within a given document or corpus. It is a key metric used in natural language processing and information retrieval tasks. TF is calculated by dividing
   Term frequency (TF) refers to the numerical representation of the occurrence of words or terms within a given collection of documents. There are several types of Term Frequency (TF) measures, including Raw TF, Logarithmic TF, Binary TF, and Augmented TF.

2. **The Concept of Inverse Document Frequency (IDF)**

   The IDF (Inverse Document Frequency) values are calculated for every token (word) in each document within the corpus.
   The calculation of IDF is performed using the following formula:

$$idf = \log \frac{D}{df}$$

   Where:

   idf = Inverse document frequency
   D = Total Documents
   df = Frequency of documents from term
   log = To minimize the effect relative to tf
   W = $t\ f\ x\ i\ df$

   The term weight is calculated using the formula
   Where:

   W = Weight of document
   tf = Frequency term
   idf = Inverse document frequency

3.5.3.2 Cosine Similarity Method

The following equation can be utilized to determine the value of cosine similarity between vectors (Yunanda, Nurjanah, & Meliana, 2022).

$$im\ (q, d_j) = \frac{q, d_j}{|q|x|d_j|} = \frac{\sum_{i=1}^{t} w_{iq} x\ w_{ij}}{\sqrt{\sum_{i=1}^{t}(w_{iq})^{\ 2}}\ x\ \sqrt{\sum_{i=1}^{t}(w_{ij})^{\ 2}}}$$

Where:

q = Vector query, which will be compared for similarity
d = Vector document j, which will be compared for similarity
| q | = Length of the query vector
| d | = Document vector length j

Wiq = Weight of the word i in the query q
Wij = Weight of the word i in document j
The recommendations produced by the engine are presented to the user via a user interface.

3.5.4 Web-based User Interface

A web-based user interface is designed to serve as an intermediary between the recommendation algorithm and the user. The user utilizes this interface to submit query data, which is then used to search and get the possible project supervisor that closely matches the user's requirements. The integration of the recommendation algorithm is included in the web-based application. The web-based component of the recommendation system is written in Python programming language, and the interface is developed using Django, a web framework written in Python. Because of the Django Web Framework's great and robust features and its inbuilt tools for web development, Django is utilized as the web system's back-end, which is responsible for providing the user with requested data (Madurapperuma, Shafana, & Sabani, 2022). Python was used to script the backend, whilst HTML, JavaScript, and CSS were utilized for managing HTTP requests, forming the front end of web development.
The design of frontend web pages prioritizes user-friendliness and alignment with actual scenarios, therefore avoiding the need for users to manually input codes or instructions. The project resource data in the database can be accessed by the system user using the web interface.

Figure 3.4 illustrates the fundamental aspects of the web application process, including the frontend and backend components.

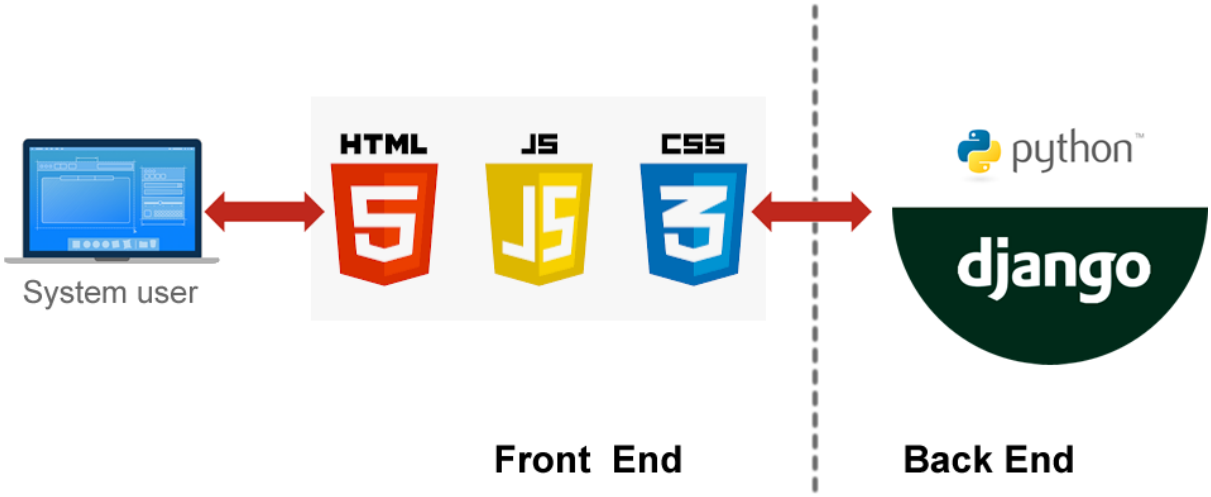

Figure 3.4: General Basics of the Website Process

3.5.4.1 What is Django?

Django is a Python-based framework for creating web applications. The Framework offers a set of regulations, frameworks, and capabilities that enable the utilization of Python code and libraries on the backend of our web application. Python is the programming language that is used for the purpose of working with Django. Subsequently, Django has the capability to engage with our web applications in order to transmit data to the end user of such web application (Kavander, 2022).

3.5.4.2 Why Use Django?

In our bid to realizing the functional and non-functional requirements of our recommendation system, which combines elements of Machine Learning and Software Engineering, we chose Django as our choice web application development framework. This decision is based on the following rationales for Django (Veeresh & Parvathy, 2022):

1. It enables fast development
2. Numerous common features are included.
3. It is regularly updated and has robust security measures.
4. The scalability of the system is really pronounced.
5. It is very versatile with Python and adaptable in using the Python programming language.
6. Django is renowned for its comprehensive built-in Python modules that take care of common web application features. Some of Django's built-in functionalities include:

    a. Administration
    b. Authentication
    c. Database Interaction
    d. Security

7. Since it uses Python as its programming language, Django enables seamless access to a wide array of Python libraries.
8. Our Machine Learning-enabled recommender system makes use of algorithms built with Python programming language. By using Python and its associated tools, we are able to seamlessly incorporate the system into our codebase, leveraging the capabilities provided by the Django framework.
9. The use of this Django technology facilitates the extension of Python-based projects into interactive web-based applications.
10. Interestingly, some of the most robust popular web applications use Django, including Instagram, Spotify, YouTube, Pinterest, Disqus, Dropbox, Eventbrite, etc. (McDonald, 2020). This indirectly implies that if Django is good enough for these top tech companies, then it should be suitable for our application too.

From the Django point of view, the general basic website process described in Figure 3.4 can be x-rayed for better comprehension as revealed in Figure 3.5.

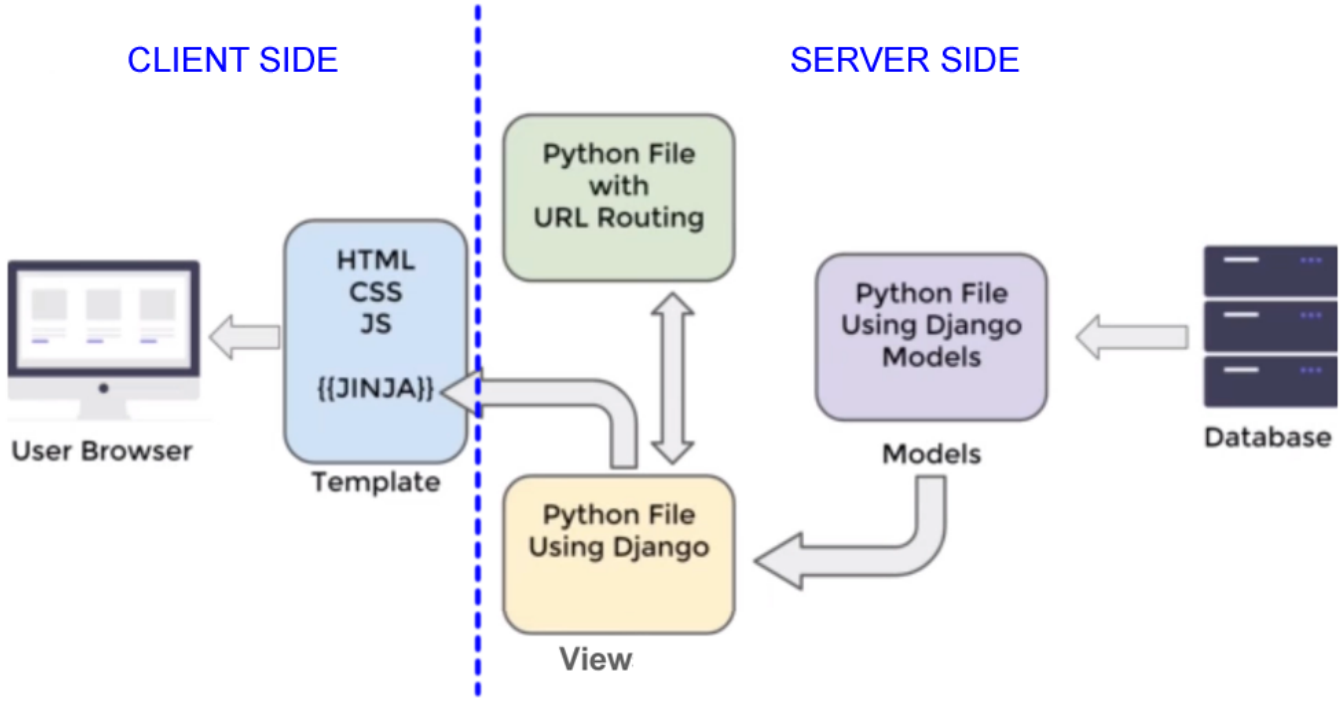

Figure 3.5: How Django Works: Communication between User and database in Django web Framework

3.5.4.3 Key Features of Django

Django is centred around the **Model-Template-View (MTV)** structure. Django factors what a typical user would do around web-based applications, which include collecting information from the database all the way to the user browser, analyzing the data, updating and saving it back to the database. These all happen around the MTV structure. The term Model in MTV is a Django concept for interacting with databases (Vamsi, Lokesh, Reddy, & Swetha, 2020).

Figure 3.6 shows a Model Template View (MTV) Architecture of Django Framework with the sectionalized components to give a descriptive view.

Template: The use of {{JINJA}} enables the direct insertion of information from a Python file into a template, such as HTML, CSS, or JS (Ghimire, 2020).

Views: The Views component, views.py, is a Python file containing a collection of functions that enable the injection information into the template. This feature enables the use of several libraries, facilitating data processing and the seamless integration of information into the template in a format compatible with the user's web browser. The View component operates in conjunction with URL routings defined in the URLs.py file, which is an additional Python script that specifies the mapping between views and corresponding URL routes. The view is often linked to a model.

Models: Models are a specific component inside the Django framework, serving as a representation of a database and its corresponding table. The models.py file is often referred to as another Python file in the context of programming. When using Models in Django, users are

relieved from the burden of directly handling SQL queries and managing the underlying database operations.

Models provide a means of interacting with a database using the Python programming language and the Django web framework. This encompasses the fundamental interactions with a database, often referred to as CRUD: Create, Read, Update, Delete (Christie, et al., 2020). Databases allow us to use information we can store on our website. The Django Model is the component that interacts with our database. The database used in this research is an SQL-based database as opposed to a NoSQL database. SQL databases are tabular, similar to a spreadsheet like Excel, while NoSQL stores data in key/value pair format. There are lots of SQL databases, including MySQL, SQLite, PostgreSQL, MS SQL and lots more. Django integrates seamlessly with most SQL engines, making switching to another SQL engine easy with few updates of the settings.py rather than rewriting Python Django code. SQLite is used in this research work as it comes already installed with Python.

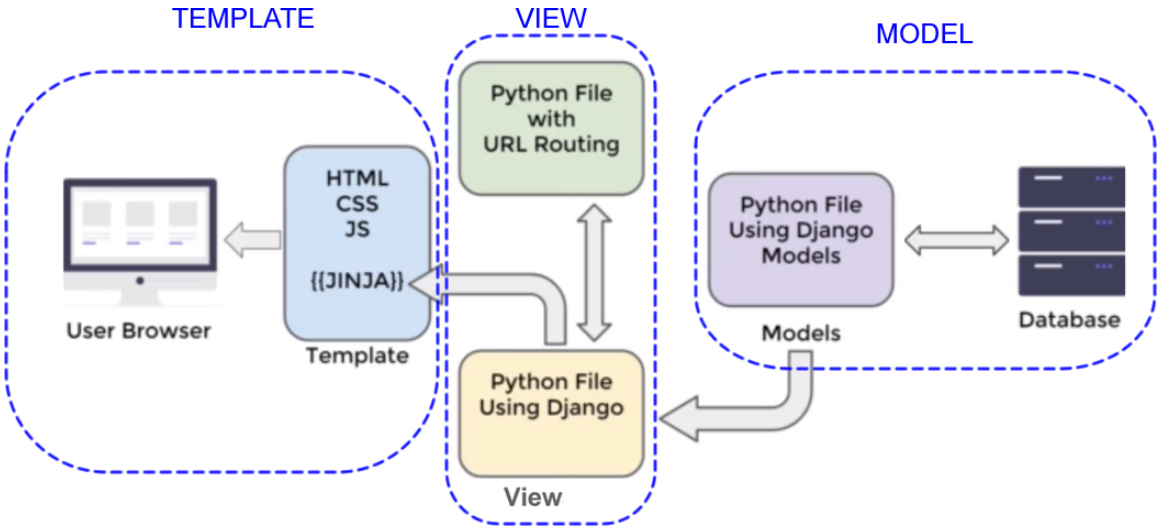

Figure 3.6: Model Template View (MTV) Architecture of Django Framework

Since our recommendation system is highly reliant on data interaction between the models and the database, with lots of connectivity, the aspect of the Django framework that handles data analysis, Machine Learning and the like is the application logic. Figure 3.7 shows the Django Framework Expanded View including the Application Logic (Machine Learning) component.

You can also have many more Python files or application logic. e.g., App.py and you just connect them through import connecting to the Python Views.py file and Models back and forth or even Models directly to the View or whether you're using some application logic (PS & Chaba, 2023).

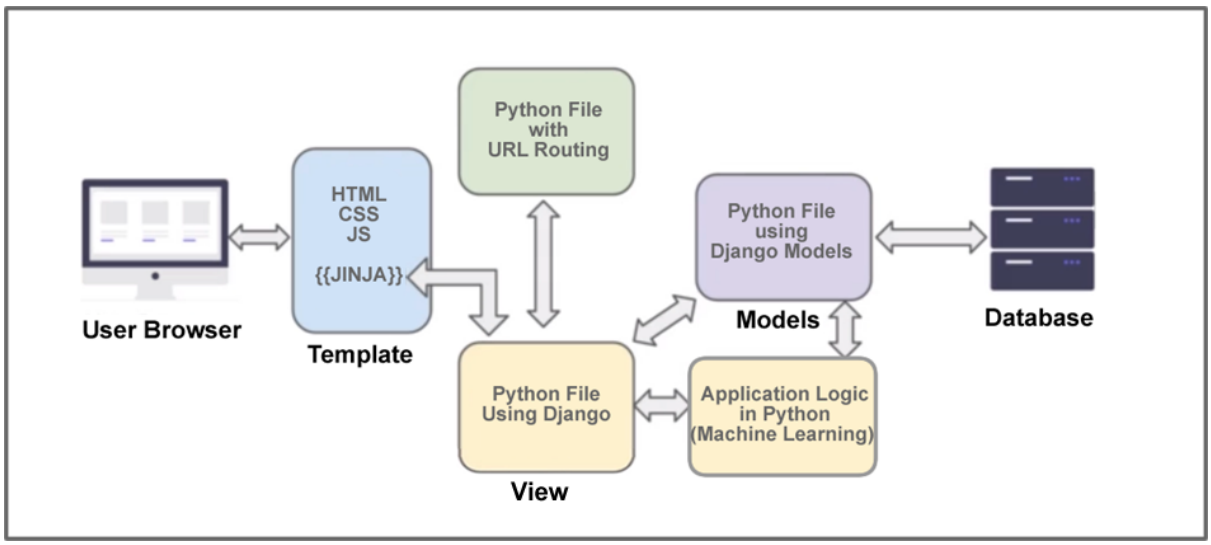

Figure 3.7: Django Framework Expanded View including Application Logic (Machine Learning) component

3.6 Research Design

In this stage, going by the functional requirements and the ultimate goal of the project supervisor recommender system, a number of designs are needed to illustrate the interactions between various systems, users and stakeholders. This includes the Use Case diagram (See Figure 3.8) and implementation flowchart (See Figure 3.9).

3.6.1 Use Case Diagram

A Use Case Diagram is a visual representation that illustrates the potential interactions between a user and a system. Figure 3.8 displays the Use case diagram for our recommender system. The Unified Modeling Language (UML) employs diagrams to provide a concise representation of the system's users, also referred to as actors, and their interactions with the system. The Figure displays the use case diagram, which effectively illustrates the system scenarios, system goals, and scope.

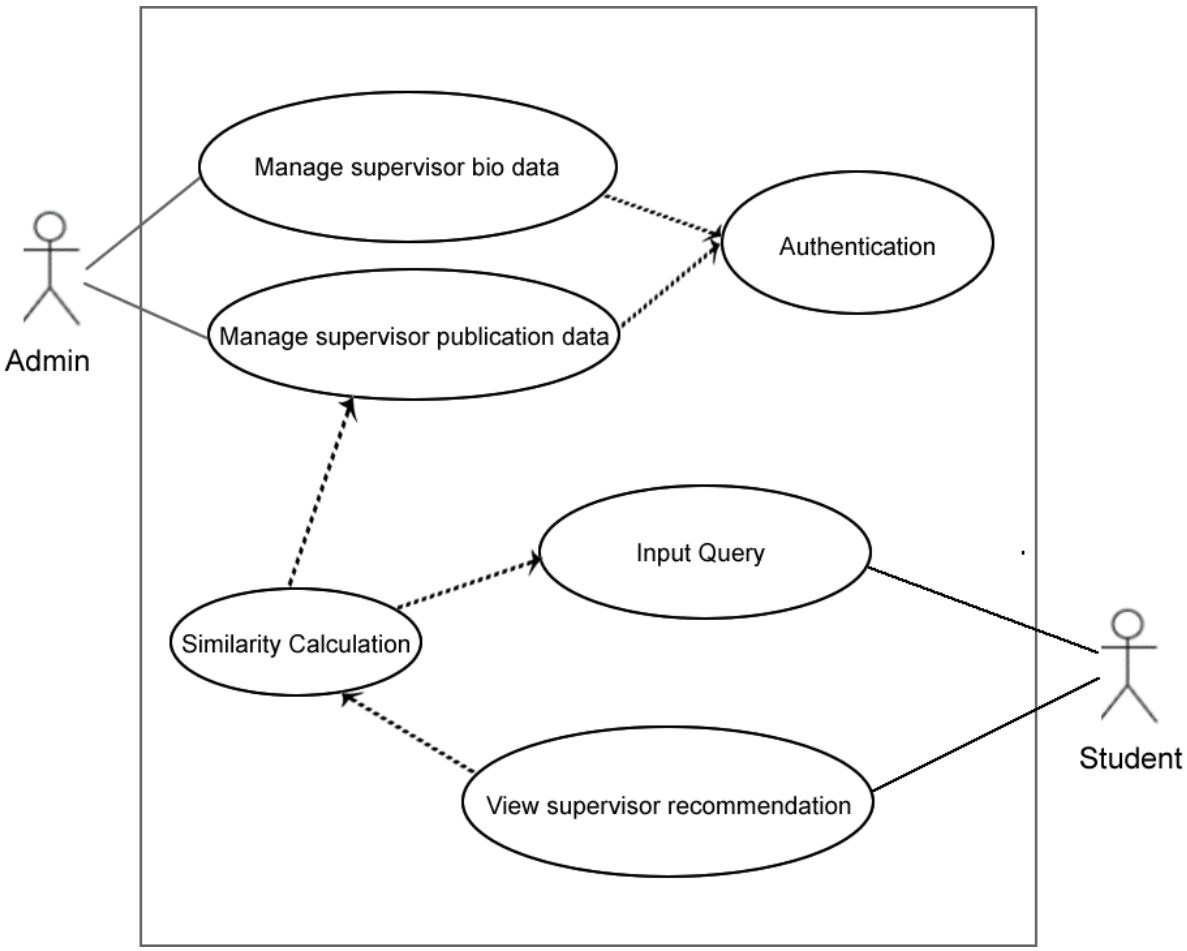

Figure 3.8: Project Supervisor Recommendation System Use Case Diagram

The supervisor's recommendation system consists of two actors: the admin and the students. The initial actor in this context is the administrator, as depicted in the accompanying illustration. The administrator possesses the capability to oversee lecturer data, including tasks such as inputting new lecturer data, deleting existing lecturer data, and modifying lecturer data. The administrator has the ability to manage both the lecturer data and the lecturer research data once logged in. The second actor is identified as a student. Students are not required to log in to access the system. However, they are able to view data pertaining to lecturers and previously published research publications. The research proposal requires students to input the title, abstract, and keywords. Once the student has entered these details, they will be able to view and identify the lecturer who is aligned with their research topic. The displayed data consists of the names of the lecturers that closely match the research proposal, arranged in descending order based on hierarchy.

3.6.2 Implementation Flowchart

The primary objective of the recommendation system is to aid students or the institution as the case may be in identifying appropriate research project supervisors by utilizing the information they provide. Figure 3.9 presents a comprehensive depiction of the flowchart for the system implementation.

The system is implemented using the Python programming language in conjunction with the Django framework. The database utilized in this system is MySQL. The implementation of the system involves the utilization of a web-based application interface for the recommender system. The task at hand involves the creation of a database and subsequent data entry. The required data includes information pertaining to lecturers, such as their personal details, as well as data related to their past research publications. The cosine similarity method is utilized to calculate document similarity in various applications.

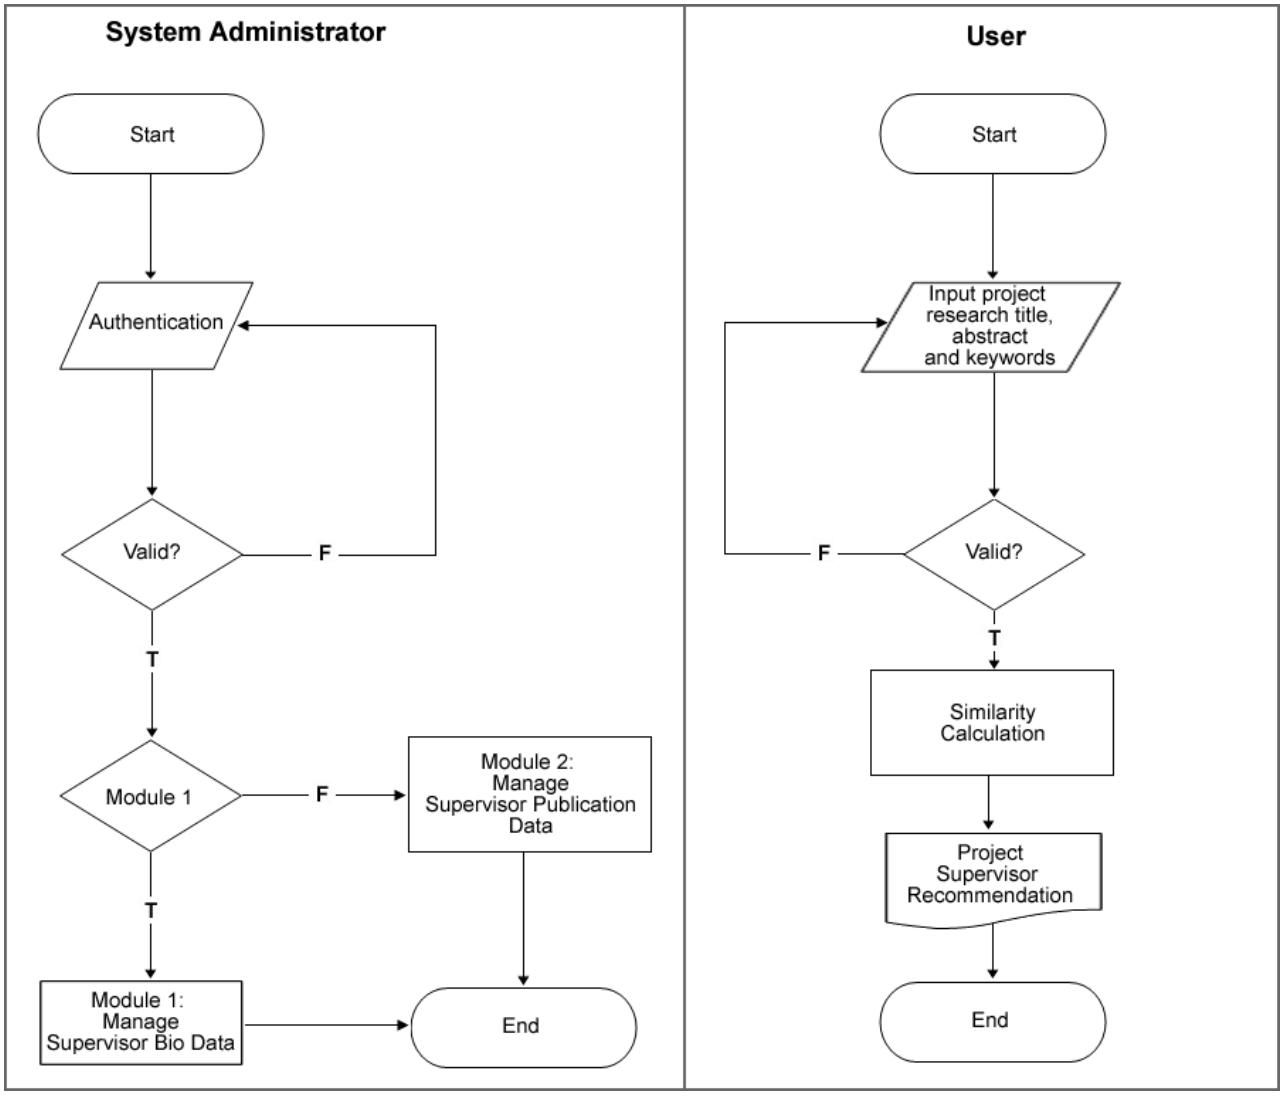

Figure 3.9: Project Supervisor Recommendation System Process Flowchart

CHAPTER 4: RESULT AND DISCUSSION

4.1 Preamble

Preceding chapters and discussions took us through various sections stating in clear terms the research aim, scope, and background. Relevant works of literature buttressing our undertakings and solidifying our strategies in employing the right methodology were also looked into extensively. The major goal here is to analyze the performance and efficacy of the supervisor recommendation system in the context of Machine Learning and Natural Language Processing tasks implemented within the Django web framework.

We want to see how effectively the system can use student inputs and a content-based filtering approach of recommendation system using a cosine similarity matrix and algorithms to identify and suggest appropriate project supervisors based on close proximity between students' project proposal query and past research publications of potential supervisors.

4.2 System Evaluation

Following the methodology deployed in the course of this research with the aim of developing a project supervisor recommendation system, the system will be evaluated along the following milestone objectives:

1. To build a dataset from scholarly publications of selected lecturers with data extracted from the publications listed on their Google Scholar profiles.
2. To provide a web-based user interface for inputting student project proposal data and displaying the resultant machine learning recommended project supervisor.
3. To develop a suitable model with a text similarity algorithm that can be integrated into the system.
4. To Introduce administrator privileges into the management of the overall system, which can be updated by an assigned system admin to update the current list of supervisors' bio and the supervisors' publications data.

Further assessment will focus on determining the accuracy and quality of the system's suggestions.

The study's first phase involves outlining the process used for dataset collection, whereby a CSV dataset including supervisors' bio-data and supervisors' past research data was acquired. This section examines the technical implementation details of the recommendation algorithm, with a focus on the use of content-based techniques, particularly the use of cosine similarity as a metric for measuring the similarity between proposed student project profiles and supervisor research profiles. The integration of the algorithm within the Django framework project is also explained. Moreover, the evaluation process encompasses the collection of student input, the implementation of the recommendation algorithm, and the examination of the system's suggestions in comparison to the ground truth in order to evaluate their accuracy and efficacy.

4.3 Results Presentation

The project supervisor recommender system is implemented as a web application, including two distinct sections: the Admin Section and the User Section. The recommendation system could be further categorized into two distinct components: The Front-end and the Backend. Figure 4.1shows the Front-end and Backend component of the Project Supervisor Recommender System.

1. The Front-end encompasses many components, including the student's query form page, the list of prospective supervisors' page, the consequent project supervisor suggestion result page, and the Admin web pages.

2. The Backend, including the database and machine learning components, maintains the overall operation of the system.

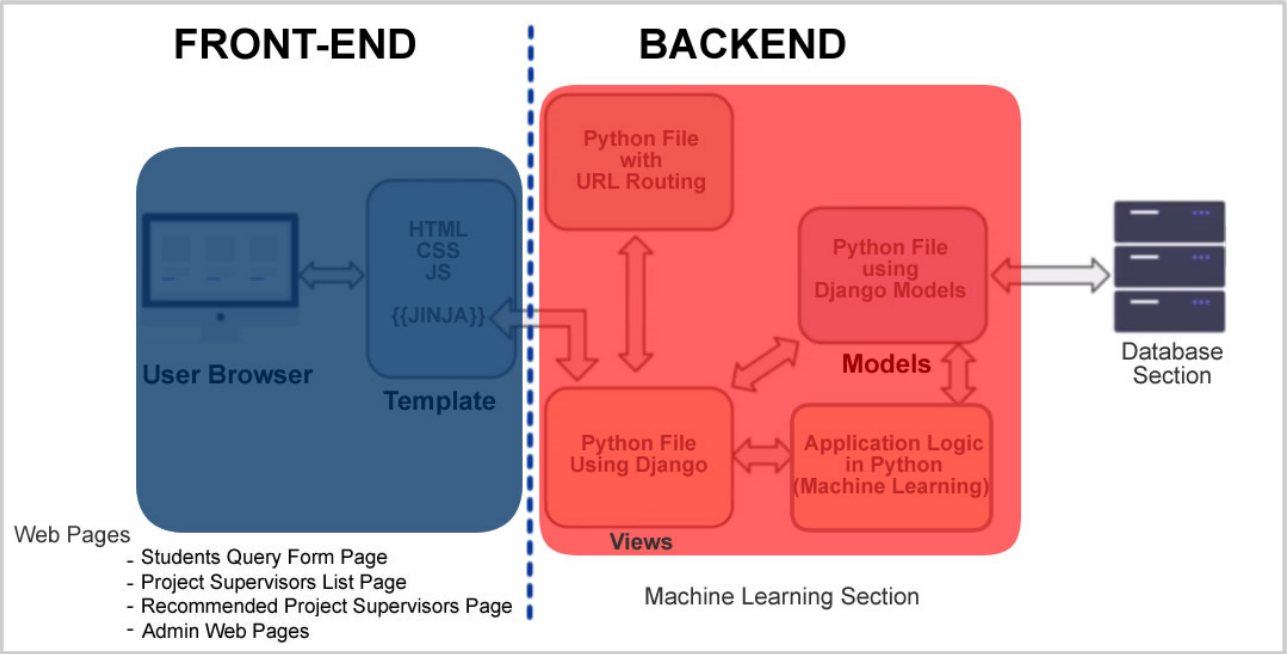

Figure 4.1: The Front-end and Backend of the Project Supervisor Recommender System

4.3.1 Setting up the Django Project/Environment

Following the system requirements for installing Django, the latest version of Python is downloaded from python.org and installed on the system.

After installation, a directory is created on the system and named "ACETEL". Inside ACETEL, another directory is created and named "recommender_system"

The next step is switching to the directory for the Django project, that is, "recommender_system and install Django using the command below.

Pip install django

Now, we are ready to create our project using the **django-admin** tool. Normally, this tool is used to launch a project in Django, **django-admin**. The tool or command launches a project in Django, which will automatically create a set of subdirectories and files for us. By default, the tool comes installed when PIP installs Django.

At the command prompt, we navigate to the recommender system directory and type:

django-admin startproject recommender_system

The **startproject** subcommand creates a new subdirectory (recommender system). Running django-admin on the system for the first time will possibly trigger this error message:

"django-admin' is not recognized as an internal or external command, operable program or batch file"

This error occurs for two main reasons:

1. Not having Django installed before issuing a **django-admin** command.
2. Not having Python in your user's PATH environment variable.

So, the solution deployed was to create a virtual environment, activate it, and install Django before running the **django-admin** command. The steps are listed below:

Creating a virtual environment

python -m venv venv

Activating the virtual environment on windows command prompt

venv\Scripts\activate.bat

Installing Django in the newly-created and activated virtual environment

pip install django

starting the recommender system Django project

django-admin startproject recommender_system

This command creates a new project directory and automatically creates a set of directories used in most Django projects.

This creates the following files and folders:

- **recommender_system**
  - **recommender_system**
  - manage.py

The command creates a **recommender_system** folder as a top-level directory and another **recommender_system** directory at the same level as the manage.py file. The recommender_system folder at the top-level directory can be changed to another name, but we decide to stick with the same name.

manage.py is a Python file for a bunch of command line utilities that let you interact with Django in various ways. This was used extensively in the course of developing our web application. Django admin and manage.py have some overlaps that will be explained subsequently. Manage.py is a Python command file to manage your project overall.

The subdirectory **recommender** folder contains a bunch of Python files, which include:

init.py This is an empty Python file that just tells Python that this directory should be considered a Python Package

settings.py This is a settings or configuration file that we would be editing at several project development stages of our Django recommender system project development.

urls.py This is where we are going to point the views throughout our website. We can take it as the table of contents for the Django-powered site. It is so important in the life of our project. It is synonymous to saying, “dispatch this view to this URL.”

asgi.py That's the entry point for asgi-compatible webservers to serve our project.

wsgi.py That's the entry point for wsgi-compatible webservers to serve our project.

To run the server, we typed in this command at the top-level recommender directory:

python manage.py runserver

At first, this command will complain of some unapplied migrations. This is displayed in Figure 4.2. However, it is in order at this stage, as this will be handled much later when we start making use of commands like "**makemigrations**" and "**migrate**" when interacting and working with models to handle our data.

With everything fine with our configurations and commands at this stage, the server should start running at this URL - http://127.0.0.1:8000

Figure 4.2: Cropped Screenshot of python manage.py runserver command in VSCode Terminal

Holding CTRL + clicking on the URL will launch the running server in a browser.

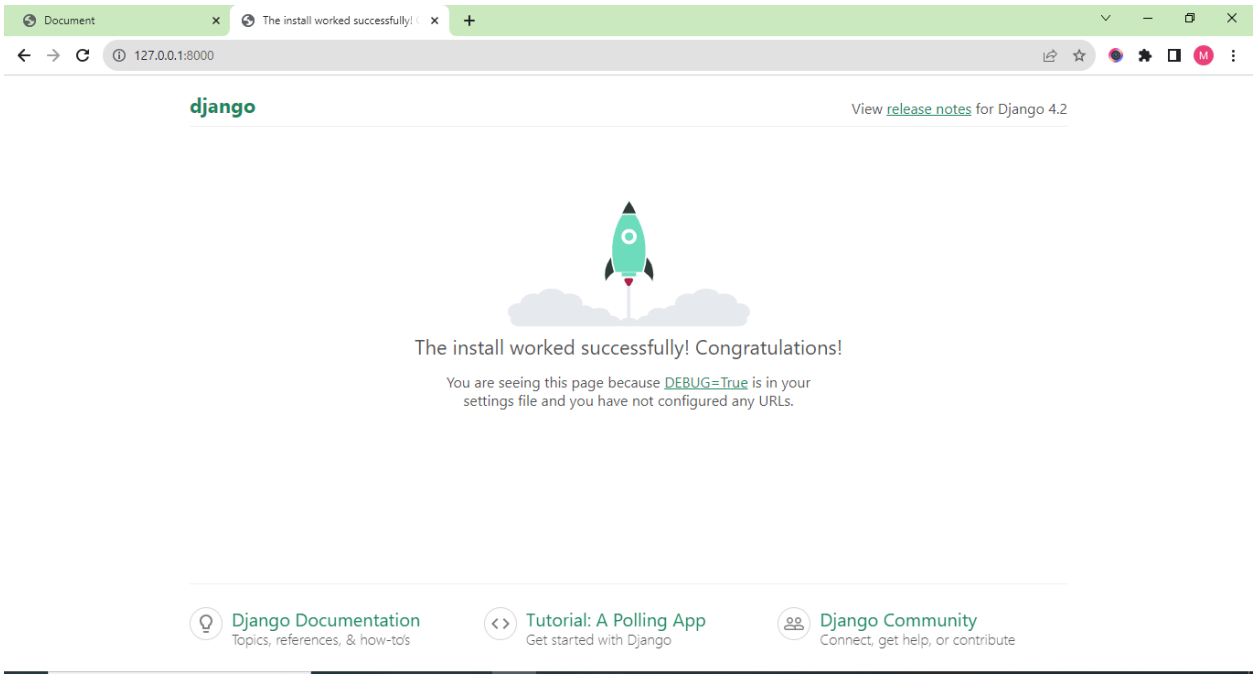

Figure 4.3: Django Server Running in a Web Browser

The server is running at a default port of 8000, even though it can be changed to another port.

4.3.2 Creating our Django Applications (App)

Our Recommender System Django project is classified into three separate components: applications (**apps**) in Django. The term 'Django app' should not be confused with the term 'web app,' which refers to a website or web application on the web, whereas a 'web app' is a component of a single Django Project (web application). Because each Django app should cover a separate functionality for a website, it is much easier to structure our coding across applications. For this project, our three apps handle the functionalities listed as follows:

1. App for Supervisors' bio record management – **supervisors_bio_app**
2. App for Supervisors' past publication management – **supervisors_publications_app**
3. App for Recommendation system – **recommender_engine_app**

Figure 4.4 gives a graphical description of our Django Recommender Project structure with the supervisors_bio_app, supervisors_publications_app and the recommender_engine_app.

Figure 4.4. Our Django Recommender Project Structure with Django Apps

To create our Django apps (supervisors_bio, supervisors_publications and recommender_engine), while in the same directory as **manage.py**, we used the following command:

python manage.py startapp supervisors_bio_app

python manage.py startapp supervisors_publications_app

python manage.py startapp recommender_engine_app

This calls manage.py file to run the command line execution. This results in the creation of apps with a number of python files and directory. Figure 4.5 shows a graphical description of our supervisors_bio_app in Django Recommender Project structure.

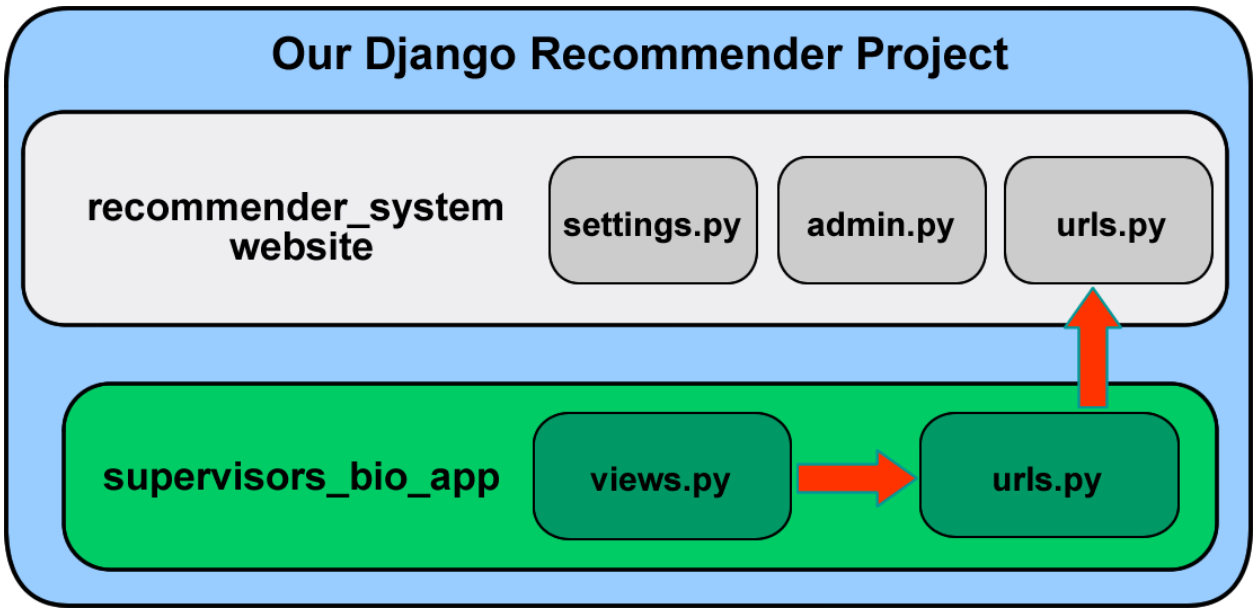

Figure 4.5: Django App in a Django Recommender Project Structure

A few aspects about our recently developed apps are worth noting:

1. The newly created apps (for example, the supervisors_bio_app) is on the same project level as the website.
2. The new app has its **views.py** which was automatically created upon creating the app.
3. The **views.py** is what allows us to have something to be displayed inside your browser. The view is analogous to a particular page on your website.
4. The **views.py** file can be directly connected to **urls.py** file on a project level, as shown in Figure 4.6. However, as we get more and more applications, it can start to get confusing. All the same, it still depends on the scope of your project.

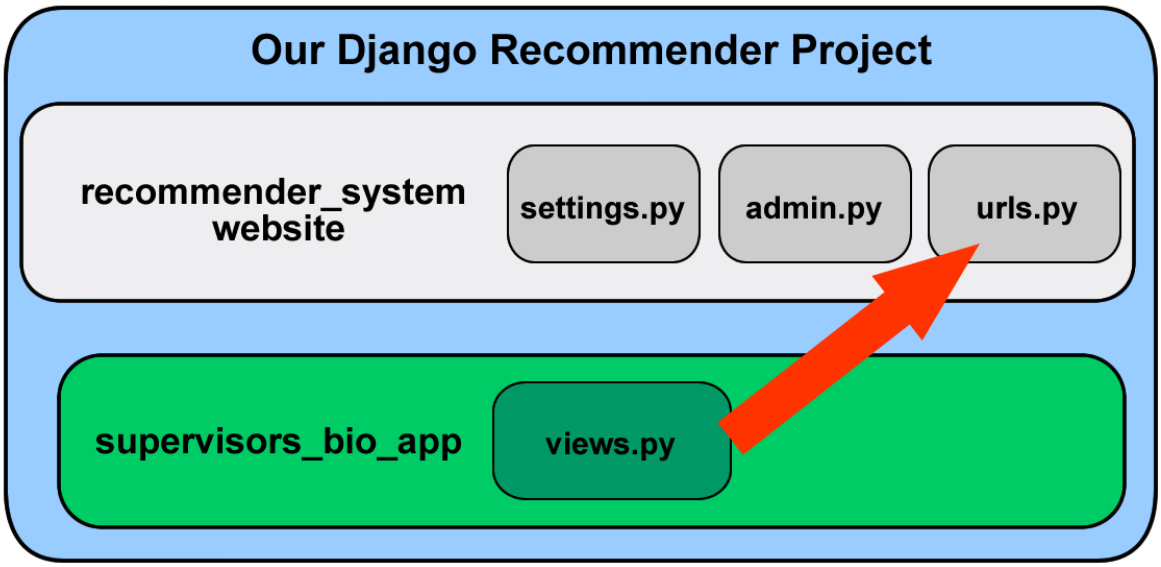

Figure 4.6: Django Project Structure with the app's view.py connected to urls.py at the project level

In more complicated applications, it is more reasonable to construct an internal urls.py file (as seen in Figure 4.7), organize components there for connection to the views, and then link the internal urls.py file of the application to the external urls.py of the project or website. This is the mode we are adopting for our Django Recommender Project.

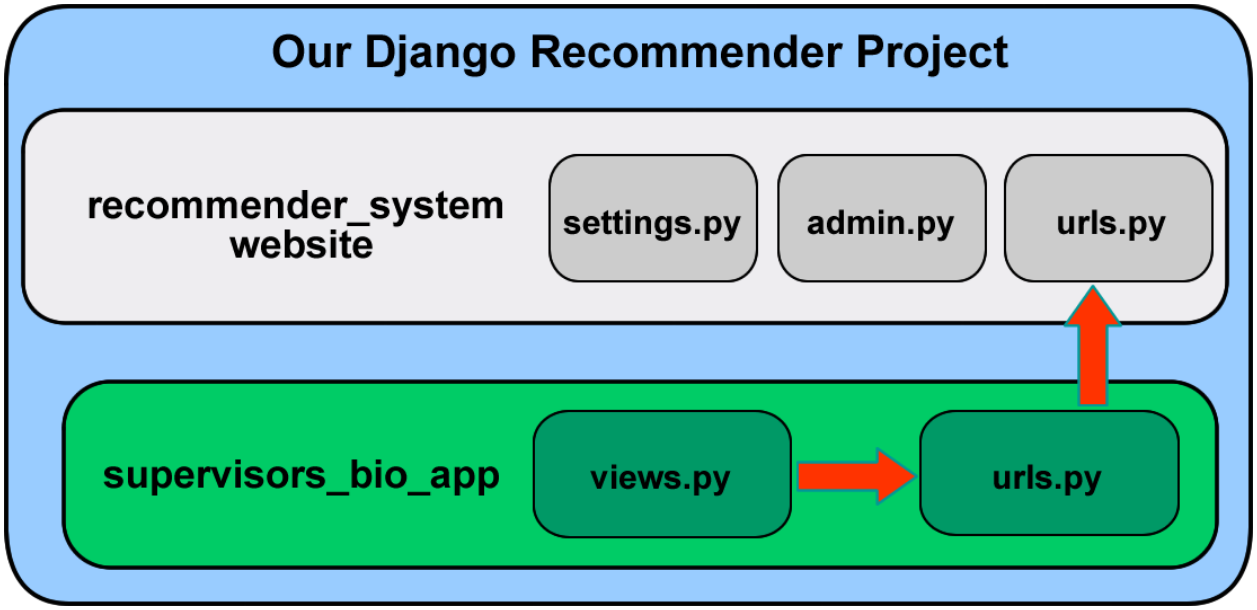

Figure 4.7: Django Project Structure - app's view.py and urls.py connected at same level

5. Django does not automatically create that urls.py inside the application; we had to create them each for all the three apps.
6. Many different types of views can be created, such as Function-based views and Class-based views.
7. We actually created our app home page view with the simple function-based view, **home()**, with a request argument (**request**), that returns a **render**. Figure 4.8 shows a cropped section of our views.py file for the supervisors_publications_app with both function-based view and class-based view in use. Several other views in our applications were also created using class-based views.

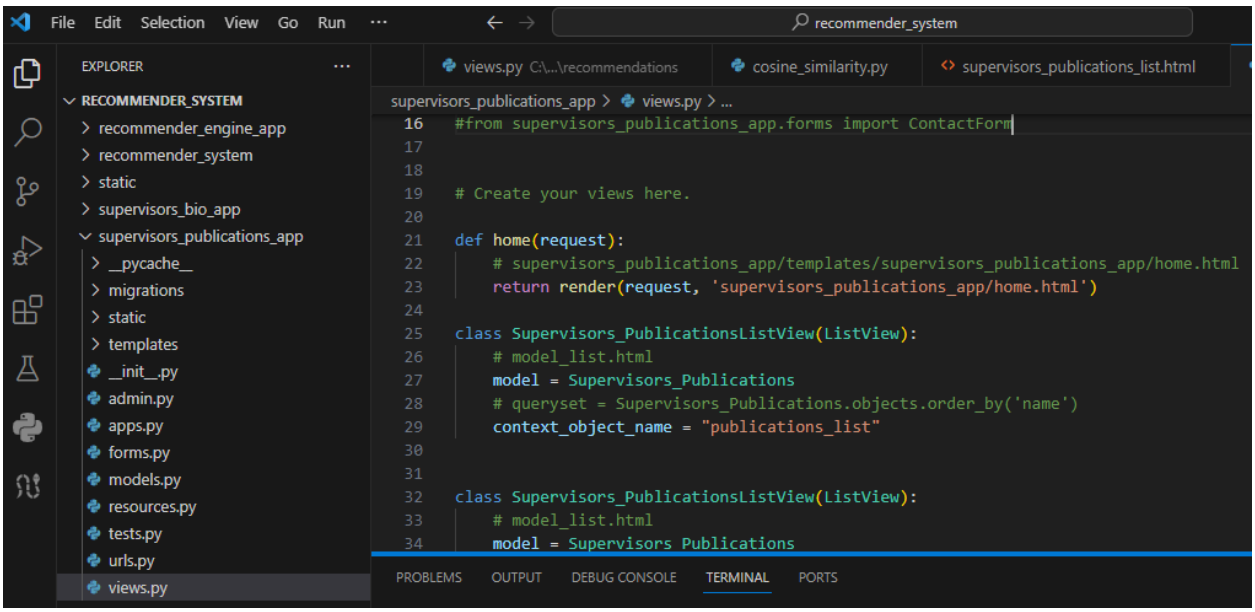

Figure 4.8: Cropped section of our supervisors_publications_app's views.py with function-based view and class-based view in use.

8. Django may be compared to a web server. In the context of traditional HTTP/1, Django gets a request and responds to it. Usually, the HTTP request that is submitted from the user's browser to the server that Django will be replying to is represented by the request argument.

9. Our urls.py files are created inside the apps, not the project directory.

Some source codes for urls.py and views.py are provided in the appendices at the end of the References section.

4.3.3 Django Templates and Static Files

In all likelihood, we would prefer not to manually put HTTP Responses or HTML code within our views.py file. Rather, we divided all of our HTML templates into a distinct directory called templates, and we used views to communicate to this directory and render the templates. We had to instruct the Django project settings where to locate these templates to connect to a template directory. While some of the templates used in this project were saved at the app level for easy access by the applications, others were stored at the project level. The steps include:

- Creating an html file inside the templates directory
- Connecting to that .html within the view
- Informing Django where to find this template directory inside of settings.py

In order for the Django Project to be aware of the app's templates directory existence, we had to register our Django apps each in the **settings.py** file under the **INSTALLED_APPS** variable as shown in Figure 4.9.

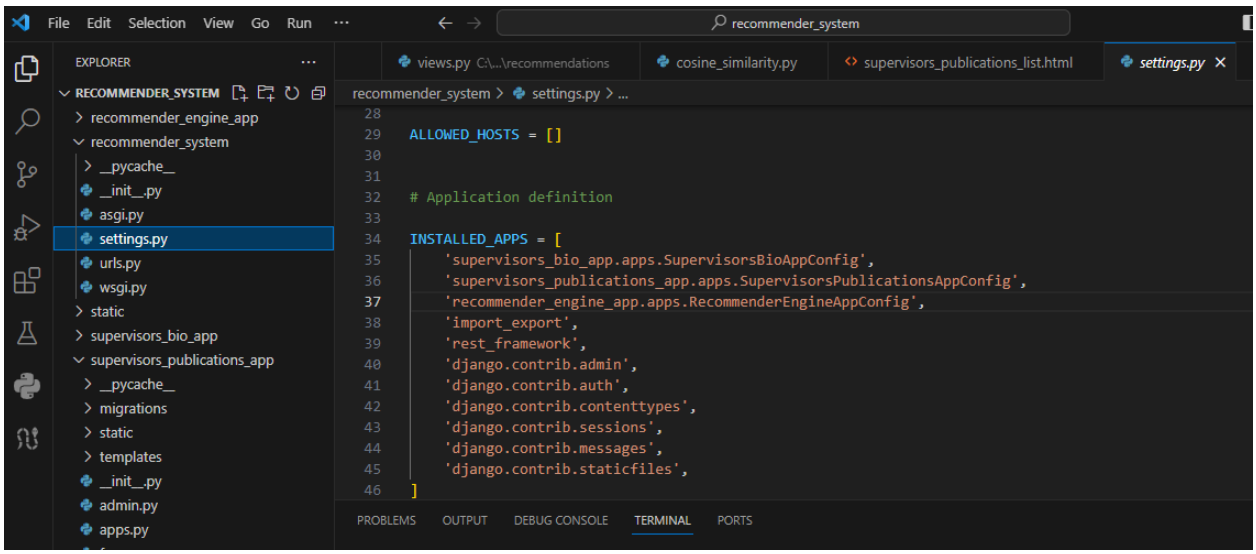

Figure 4.9: Cropped Section (Screenshot) of INSTALLED_APPS in our Django Project's settings.py file

The same process we followed in creating templates under the app directory with the app name was what we used in creating static files inside the static directory. Our static files, like images, CSS and JavaScript are placed inside the static folder.

4.3.4 Django Models and Databases

Creating a Model is similar to creating a new table in a database. Django Models are defined inside a Django app (or project) models.py file. The models class operates on a system that directly converts Python-based code into SQL commands. This makes it much easier to work with the backend database. Figure 4.10 shows Django Framework with a Focus on Models and Database. Every database table contains a name, followed by columns, each of which holds a different type of data (for instance, integers for age in years or character strings for names).

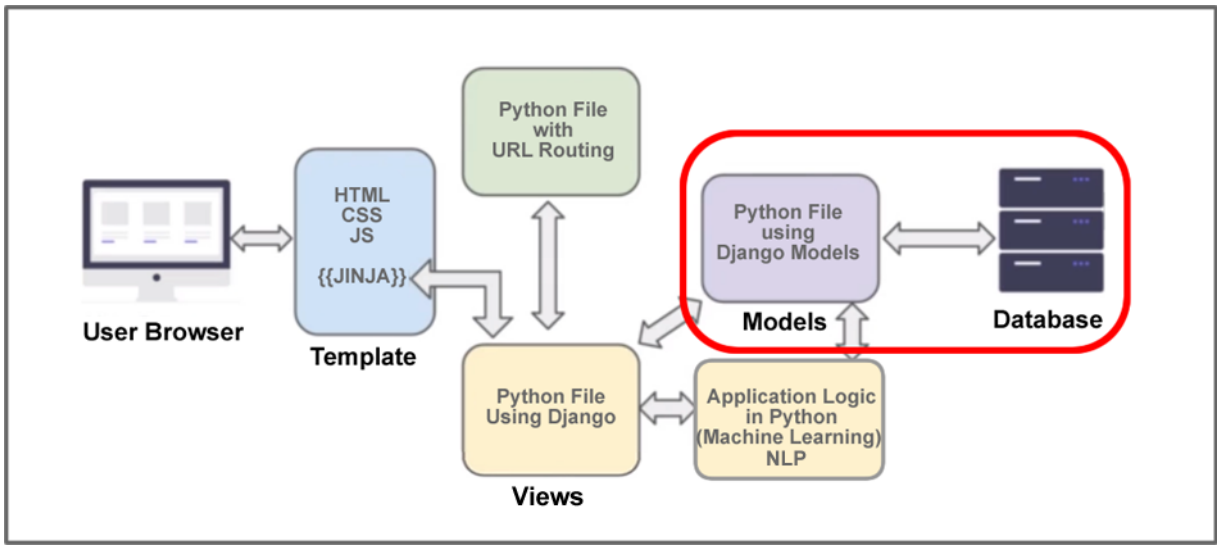

Figure 4.10: Django Framework with Focus on Models and Database

For example, our supervisors_bio_app **models.py** file code is stated below:

```
from django.db import models
```

```
# Create your models here.
class Supervisors_Bio(models.Model):
    picture_link = models.URLField(max_length=200)
    name = models.CharField(max_length=100)
    gender = models.CharField(max_length=6)
    email = models.CharField(max_length=50)
    phone = models.CharField(max_length=11)
    def __str__(self):
        return self.name
        #return f"Supervisor: {self.name}. Email: {self.email} Phone: {self.phone}"
```

This automatically converts to this SQL:

CREATE TABLE supervisors_bio_app_Supervisors_Bio_tbl (

“id” serial NOT NULL PRIMARY KEY,

“picture_link” varchar (100) NOT NULL,

“name” varchar (100) NOT NULL,

“gender” varchar (6) NOT NULL,

“email” varchar (50) NOT NULL,

“phone” varchar (11) NOT NULL,

Saving our models.py shows us that our apps’ models.py changed and are reloading. This goes to create Supervisors_Bio table in the db.sqlite3 database. Normally, there is a step to follow to see the Python code and SQL generated for our Supervisors_Bio table.

In the terminal, typing this command below will make it work:

python manage.py makemigrations supervisors_bio_app

However, to make it work, we had to register our application as a configuration within INSTALLED_APPS.

Going to our apps.py under supervisors_bio_app, we copied the class there (SupervisorsBioAppConfig) and paste under INSTALLED_APPS in setttings.py

```
# Application definition

INSTALLED_APPS = [
    'supervisors_bio_app.apps.SupervisorsBioAppConfig',
```

```
'supervisors_publications_app.apps.SupervisorsPublicationsAppConfig'
,
    'recommender_engine_app.apps.RecommenderEngineAppConfig',
    'import_export',
    'rest_framework',
    'django.contrib.admin',
    'django.contrib.auth',
    'django.contrib.contenttypes',
    'django.contrib.sessions',
    'django.contrib.messages',
    'django.contrib.staticfiles',
]
```

The format is usually **appname.apps.classname** followed by a comma.

We had already stated it before, so there was no need to repeat it under INSTALLED_APPS. We repeated the same process for supervisors_publications_app and recommender_engine_app likewise.

The next thing we did was to run **makemigrations** command, as shown below:

python manage.py makemigrations supervisors_bio_app

This command generated 0001_initial.py under the migrations directory, under the supervisors_bio_app directory. The generated code is shown below:

```
# Generated by Django 4.2.6 on 2023-11-29 03:48

from django.db import migrations, models

class Migration(migrations.Migration):

    initial = True

    dependencies = [
    ]

    operations = [
        migrations.CreateModel(
            name='Supervisors_Bio',
```

```
                fields=[
                                ('id',    models. BigAutoField( auto_created=True,
primary_key=True,   serialize=False,   verbose_name='ID')),
                        ('picture_link',   models. URLField()),
                        ('name',   models. CharField( max_length=100)),
                        ('gender',   models. CharField( max_length=6)),
                        ('email',   models. CharField( max_length=50)),
                        ('phone',   models. CharField( max_length=11)),
                    ],
            ),
        ]
```

As can be seen above, in order to uniquely identify each unique id row item in our database, it automatically generates a primary key. To see the SQL script automatically generated by Django for this table, we typed in the command below:

python manage.py sqlmigrate supervisors_bio_app 0001

This showed:

C:\Users\Hp\Desktop\ACETEL\recommender_system>python manage.py sqlmigrate supervisors_bio_app 0001

BEGIN;

--

-- Create model Supervisors_Bio

--

CREATE TABLE "supervisors_bio_app_supervisors_bio" ("id" integer NOT NULL PRIMARY KEY AUTOINCREMENT, "picture_link" varchar(200) NOT NULL, "name" varchar(100) NOT NULL, "gender" varchar(6) NOT NULL, "email" varchar(50) NOT NULL, "phone" varchar(11) NOT NULL);

COMMIT;

C:\Users\Hp\Desktop\ACETEL\recommender_system>

The next thing to do is to now run **Python manage.py migrate** to carry out all the migrations necessary in the project.

```
C:\Users\Hp\Desktop\ACETEL\recommender_system>python manage.py migrate
Operations to perform:
  Apply all migrations: admin, auth, contenttypes, sessions, supervisors_bio_app
Running migrations:
  Applying supervisors_bio_app.0001_initial... OK

C:\Users\Hp\Desktop\ACETEL\recommender_system>
```

Quite a lot of functions and operations can be carried out on our models interacting with our applications, several of which were utilized while developing our recommender system.

4.3.5. Students Query Form Page

Figure 4.11 shows the Students Query form interface where the user fills out the form containing the student's proposed project title, keywords and abstract before clicking the Recommend Supervisor button to get results from the recommendation system.

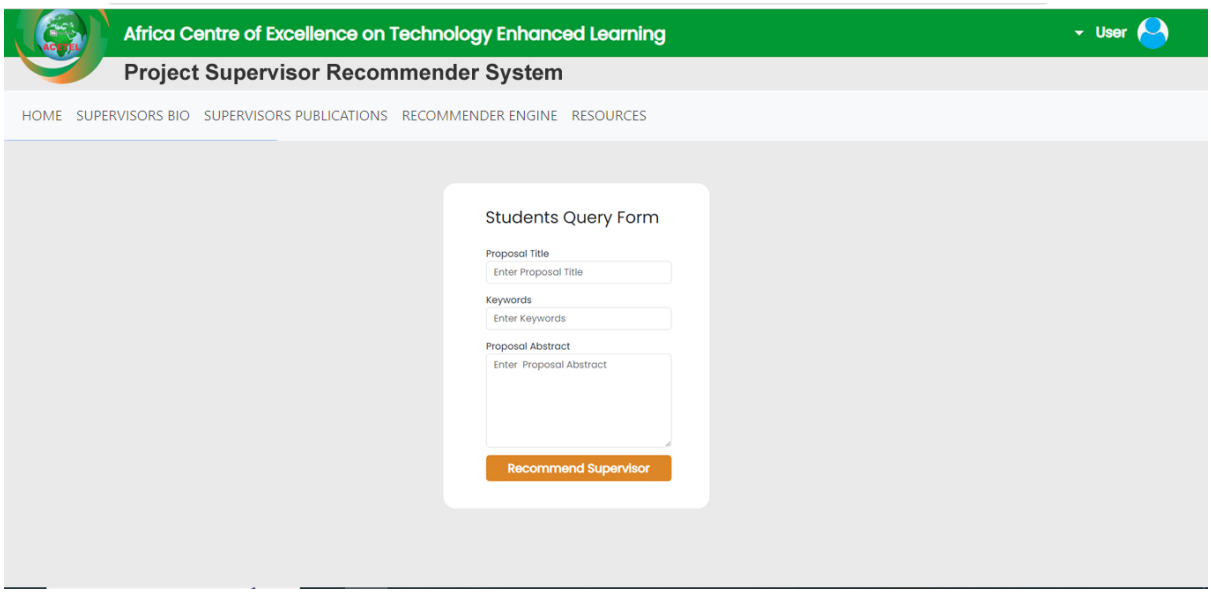

Figure 4.11: Students Query Form of the Recommender System

4.3.6. Project Supervisors List Page

Figure 4.12 shows the Project supervisors' list page. It contains list of supervisors that the System Admin had previously captured in the dataset in the supervisors short bio data dataset in the form of spreadsheet and turned into supervisors_bio table in the database. The data attributes gathered in the supervisors_bio data include prospective supervisors name, gender, email and phone.

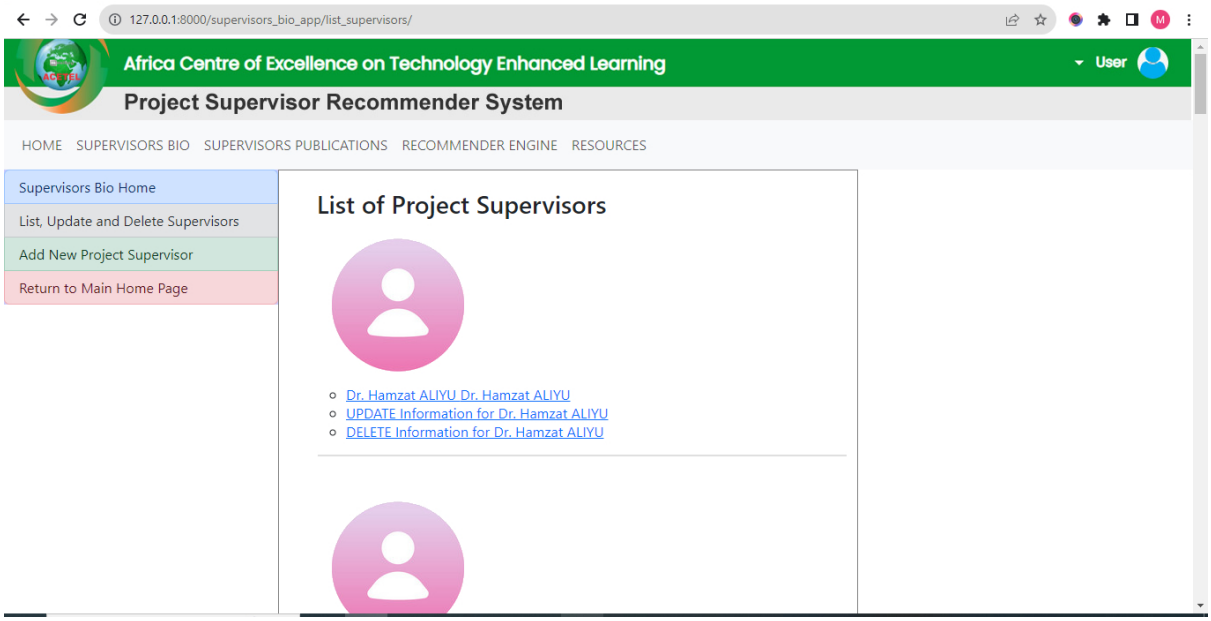

Figure 4.12: Project Supervisors List

4.3.7 Recommended Project Supervisors Page

Figure 4.13 shows a Recommended Project supervisors' page. It contains list of supervisors that the System Admin had previously captured in the dataset in the supervisor's short bio data dataset in the form of spreadsheet and turned into supervisors_bio table in the database. The data attributes gathered in the supervisors_bio data include prospective supervisors name, gender, email and phone.

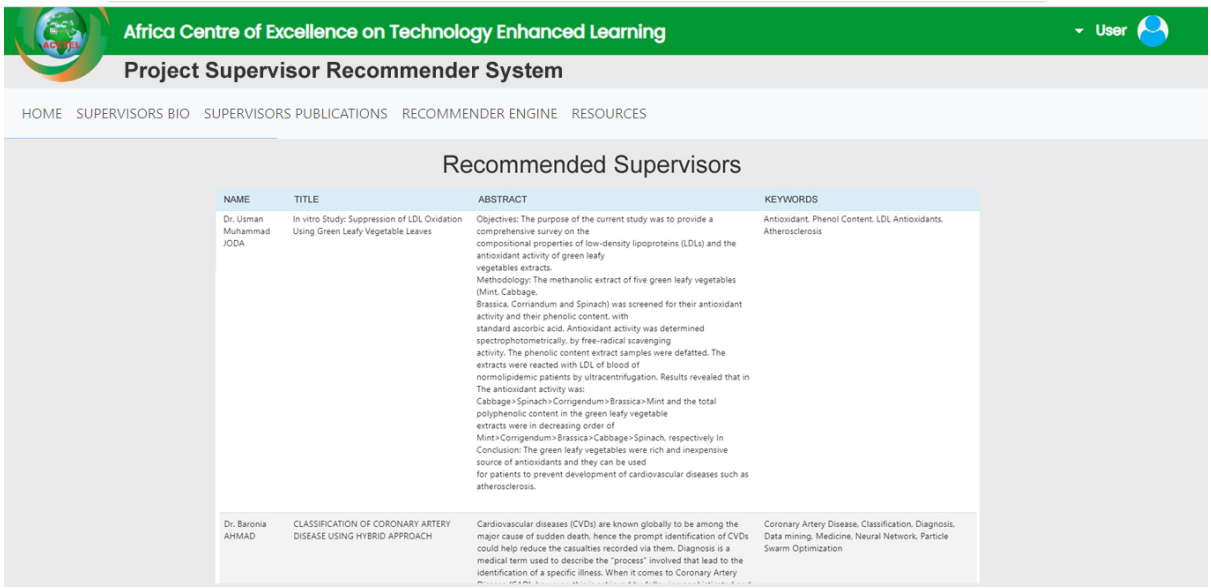

Figure 4.13 A Sample Recommended Project Supervisors' page

4.3.8 Admin Web Pages

Figure 4.14 shows the Django Recommendation System Admin Login Page while Figure 4.15 shows an Admin Portal Page. The system Admin or whatever user is given Admin privileges can frequently update the Supervisors list as well as the Supervisors' research publications as soon as more updates are available. This also improves the Machine Learning task because more fresh and growing data will eventually make the Recommendation engine more

intelligent as the model learns from data. Remember, Machine learning learns from data without being explicitly programmed.

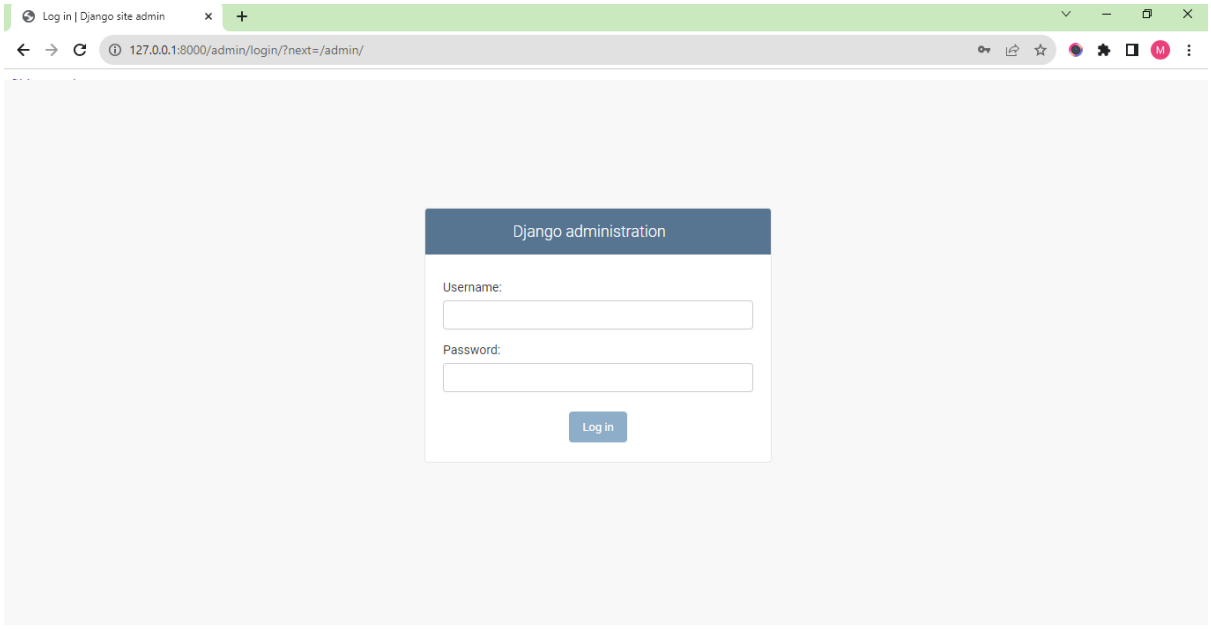

Figure 4.14: Django - Recommendation System Admin Login Page

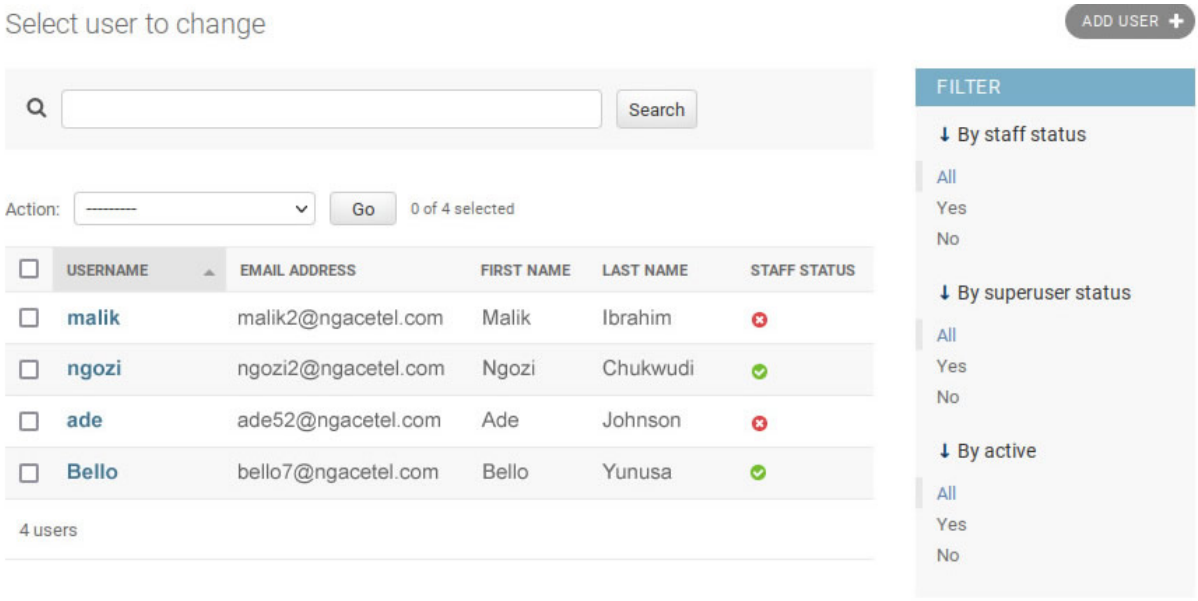

Figure 4.15 Project Recommender System Admin Page

Access to the backend is restricted to those with administrative privileges, who are mandated to sign up or log in. The authentication process for administrative personnel will be conducted via the Recommendation System Admin Login Page. However, it is not necessary for a typical user seeking access to the recommender system for project supervisor recommendations to register or log in. Although, users have the option to register for any future correspondence and get information about the project supervisor recommender system.

4.3.9 Machine Learning Section

The system is built using Django as the web framework. In this particular case, the integration of the application logic aspect of the Django web framework with the Model and View components of Django is represented as the Machine Learning section, as depicted in Figure 4.1. This integration is essential as it facilitates the collaborative functioning of these components in order to achieve the backend functionality of project supervisor recommendation. The system operates in a unidirectional manner, starting with students inputting the title, abstract, and keywords. Subsequently, the system will engage in computational processes to provide appropriate recommendations for lecturers, drawing upon data provided by users or students. Figure 4.16 illustrates the internal organization of the Django project directory, whereby each individual directory has a distinct purpose. The backend directory serves as the foundational component of the project, housing the configuration and settings for the Django applications.

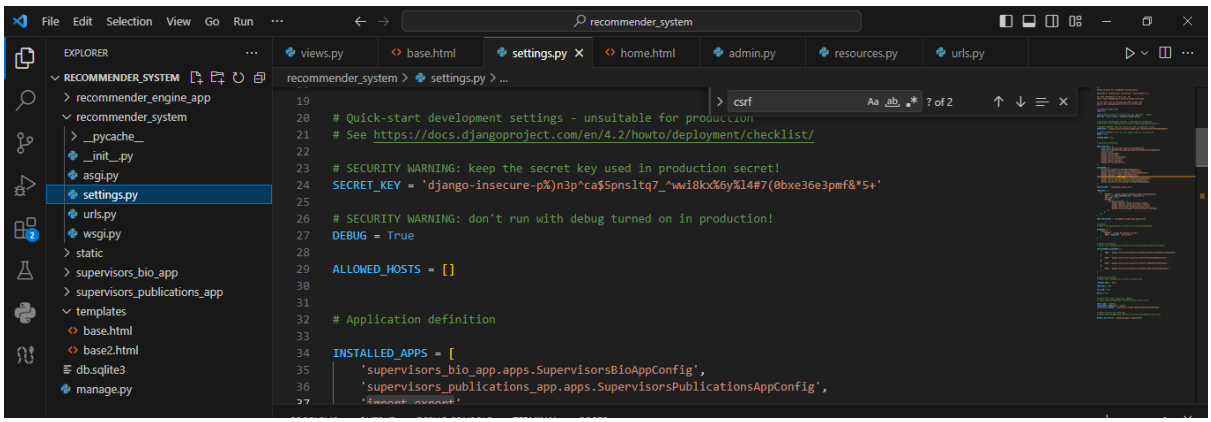

Figure 4.16: Internal organization of Django Project Directory

The cosine similarity algorithm of the content-based filtering system is also implemented in a recommendations app designated solely for that purpose as shown in Figure 4.17. It is able to collect student inputs, executing the recommendation algorithm using the implemented system, and generating supervisor recommendations based on project profiles. The results obtained from this process, such as the recommended supervisors for each student input, are presented to the views.py Python file to facilitate a visualization as presented to the user browser in Figure 4.13. This displays the top three closest matching suitable supervisors as per the submitted student project proposal data.

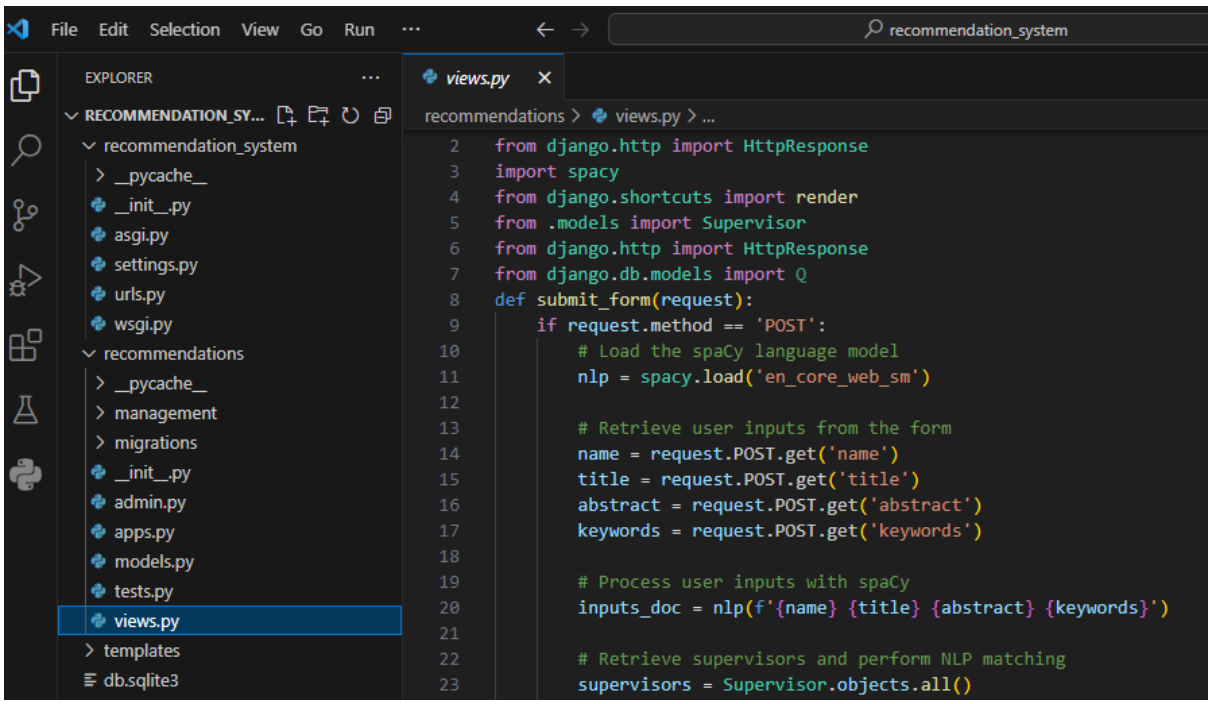

Figure 4.17: Implementation of the Recommendation System Cosine Similarity Algorithm in Django

4.3.10 The Database Section

The Project Supervisor Recommendation System is powered by data and requires significant technological resources for its implementation. From the initial stage of data collection to the final presentation on a user interface, various processes are involved, including data analysis, planning, text mining, data mining, preprocessing, processing, filtering, and the application of machine learning algorithms. These algorithms enable the construction of intelligent models that can learn from data without the need for explicit programming. The end result is most cases is worth the effort invested. The original data provided for this study consisted of a compilation of department project supervisors. This information has been successfully included into our research by integrating it into our SQLite database. Based on the information provided on the official SQLite website, it can be broadly said that websites with a daily viewership of fewer than 100,000 should be able to effectively use SQLite. The anticipated daily number of 100,000 hits should be regarded as a conservative approximation rather than an unequivocal upper limit. Research has shown that SQLite has the ability to effectively manage a volume of traffic that exceeds the previously indicated quantity by a factor of 10. The second dataset was obtained by extracting information from the Google Scholar profile pages of the lecturers from ACETEL who were captured in this research. A total of 1,137 research papers were extracted throughout the mining procedure. Furthermore, the integration of this feature has been implemented inside the SQLite database in the Django web Framework. SQLite is a database management system that utilizes Structured Query Language (SQL) and consists of tables for organizing and storing data. The list of lecturers is stored in the supervisors_bio table, whilst the dataset of research papers that has been cleaned is stored in the supervisors_publications table.

4.4 Analysis of the Results

This research effectively integrates two significant domains of technology to address the objectives of the research. The two domains are Software Engineering, specifically focusing on Web Application Development, and Data Science, with emphasis on Machine Learning and Natural Language Processing. These three – Web Application development, Machine Learning and Natural Language Processing work hand-in-hand towards the execution of the project. The implementation of technology best practice strategies goes beyond recognizing a need and devising a technology-driven solution, it goes further to assembling relevant prerequisites and commencing their categorization into functional and non-functional requirements. The purpose and goals of the research became evident, along with the corresponding significant achievements. The choice selection and justification for using the Django web framework were outlined. It is worth noting that Tech giant companies like YouTube, Instagram, Dropbox, and Spotify, among others, also have their platforms developed with Django. This further reinforces our confidence in the system's robustness, scalability, security, authentication and administration. The recommendation system places significant emphasis on data, as it serves as its core and essential component. Therefore, careful measures were taken to ensure thorough data preprocessing prior to its use in the recommendation engine. This is particularly important since the presence of noise may significantly impede the efficiency of the system, contrary to expectations.

4.5 Discussion of the Results

The outcome derived from conducting a similarity assessment using Cosine Similarity between the student's query and supervisors' research publications indicates that the process for a student or a system user involves entering their proposed project title, keywords, and abstract into the query form designed for students. Subsequently, they are required to click on the "Recommend Supervisor" button, as shown earlier in Figure 4.11. The following subsections provide a breakdown of the results discussion.

4.5.1 The Searched Terms Compared for Similarity

The field components of the students' query are the same as those of the supervisors' publications in the database. The three fields are:

Title: The title is the name given to a composition. It conveys the intent that surrounds the subject of the project in simple clear terms.

Keywords: Keywords are search terms that should quickly lead one to a search intent. Keywords are not careless words; they must closely match the contents of the project.

Abstract: a brief statement or account of the main points summarizing a composition. Abstract has universally accepted standards and components for best practice. The following aspects or components should be included in a well-written abstract:

- The research problem
- The aim, goals and objectives of the research
- The research methodologies
- The conclusion of the research

A combination of this trio (Title, keywords and abstract) is what is passed as a single document for each record for analysis in our recommendation engine.

4.5.2 TF-IDF Metric in Vectorization

TF-IDF is a highly useful metric for assessing a term's importance in a document. TF-IDF has two components: TF (Term Frequency), and IDF (Inverse Document Frequency). The way that term frequency functions is by examining how frequently a certain term appears in relation to each row of data or record in our supervisors_publications table, which is equivalent to each supervisor's individual publication. Conversely, inverse document frequency examines the frequency (or rarity) of a term inside the corpus. The IDF is calculated as follows with this formula (Yunanda, Nurjanah, & Meliana, 2022).

$$idf(t,D) = \log\left(\frac{N}{\text{count } d \in D : t \in d}\right)$$

Where t, is the term (word) for which we want to measure its popularity.
The number N represents the number of documents (d) in the corpus (D).
The denominator is just the number of documents that include the term, t.

In cases where a term does not occur in the corpus at all, resulting in a divide-by-zero error, a solution is to add 1 to the current count. As a result, the denominator is (1 + count). Scikit-Learn, a popular Python library, handles it with the following formula.

$$IDF(t) = \log\frac{1+n}{1+df(t)} + 1$$

Whereas the normal formula where a term occurs in the corpus is given as:

$$IDF(t) = \log\frac{n}{df(t)}$$

IDF is needed to assist in correcting the appearance of terms like "and", "is", "the", and so on, which appear often in an English corpus. So, by using inverse document frequency, we are able to reduce the weighting of common phrases while increasing the significance of infrequent terms.

4.5.3 Combining TF and IDF: TF-IDF

TF indicates how frequently a term appears in a document, whereas IDF indicates the comparatively uncommonness of the term in the collection of documents. Our final TF-IDF value, in this case, can be obtained by multiplying these numbers together. This is shown with the following formula:

$$tf\,idf(t, d, D) = tf(t,d) \cdot idf(t, D)$$

4.5.4 TF-IDF Use Cases

TF-IDF has use cases in several applications, including:

1. **Applying TF-IDF to information retrieval.**
   Search engines are a typical example of how TF-IDF is used in the information retrieval domain. A search engine can utilize TF-IDF to assist rank search results based on relevance, with results that are more relevant to the user having higher TF-IDF scores. This is because TF-IDF can inform you about the relevant importance of a word based on a document.

2. **Applying TF-IDF for keyword extraction and text summarizing**
   Using this method, one may ascertain which words are most significant since TF-IDF assigns weights to words depending on their significance. This may be used merely to find keywords (or even tags) for a text, or it can be used to assist in summarizing articles more effectively.
3. **Feature extraction for text classifications**
4. **Document clustering/grouping**
5. **Natural language processing.**

4.5.5 TF-IDF, Cosine Similarity and the Basis for Natural Language Processing in Recommender System

Since Machine Learning algorithms frequently work with numerical data, vectorization - a procedure that transforms textual data into a vector of numerical data must come first when working with textual data or any natural language processing (NLP) activity. The process of TF-IDF vectorization is figuring out each word's TF-IDF score in relation to the content and then putting that data into a vector. As a result, every document (publication) in the corpus (collection of publications) would have a unique vector that contained the TF-IDF score for each and every word in the collection of documents. With these vectors, we can use cosine similarity to determine how similar the TF-IDF vectors of the supervisors' publications data and query input from a student project proposal are to one other.
As notably seen by the speed with which search engines provide appropriate search results for searches with TF-IDF and Cosine similarity analysis, without doubt, it is still one of the most prevalent techniques to analyze textual data. Additionally, they help websites rank better in search results pages (SERPs) by demonstrating how close they are to a certain query.

4.5.5.1 How TF-IDF is Computed in the Recommendation Engine

The TF-IDF score of the word reveals the significance or importance; as a term gets closer to zero, its score declines.
Table 4.1 shows the sample data used in calculating the vectorization result of three publications. One is doc1 which is the student project proposal, while the remaining doc2 and doc3 are from the supervisors' publications dataset. From the table, the title, abstract and keywords of doc1 were merged and passed into the doc1 variable in Figure 4.18. The same

constituents (title, abstract and keywords) each of doc2 and doc3 are merged and passed into doc2 and doc3 respectively.

Table 4.1 Sample Documents used to Calculate the Vectorization Result of Three Publications.

Documents	Author	Title	Abstract	Keywords
doc1 (Student Project Proposal)	Student	Machine Learning to Predict Cardiovascular Risk	To analyse the predictive capacity of 15 machine learning methods for estimating cardiovascular risk in a cohort and to compare them with other risk scales, we calculated cardiovascular risk by means of 15 machine-learning methods and using the SCORE and REGICOR scales and in 38 527 patients in the Spanish ESCARVAL RISK cohort, with 5-year follow-up. We considered patients to be at high risk when the risk of a cardiovascular event was over 5% (according to SCORE and machine learning methods) or over 10% (using REGICOR). The area under the receiver operating curve (AUC) and the C-index were calculated, as well as the diagnostic accuracy rate, error rate, sensitivity, specificity, positive and negative predictive values, positive likelihood ratio, and number needed to treat to prevent a harmful outcome. The method with the greatest predictive capacity was quadratic discriminant analysis, with an AUC of 0.7086, followed by Naive Bayes and neural networks, with AUCs of 0.7084 and 0.7042, respectively. REGICOR and SCORE ranked 11th and 12th, respectively, in predictive capacity, with AUCs of 0.63. Seven machine learning methods showed a 7% higher predictive capacity (AUC) as well as higher sensitivity and specificity than the REGICOR and SCORE scales. Ten of the 15 machine learning methods tested have a better predictive capacity for cardiovascular events and better classification indicators than the SCORE and REGICOR risk assessment scales commonly used in clinical practice in Spain. Machine learning methods should be considered in the development of future cardiovascular risk scales.	machine learning, cardiovascular, patients, regicor, diagnostic
doc2	Dr. Baronia AHMAD	An Improved Classification Method for Diagnosing Heart Disease using Particle Swarm Optimization	Today, the diagnosis of some of the major cardiovascular diseases, for example Coronary Artery Diseases (CAD), heart rhythm problems, Ischemic, Atrial Fabrication and so on is generally accomplished by following modern and costly therapeutic strategies performed in well-equipped medical institutions. In addition, these procedures usually require the application of invasive methods by only highly qualified medical experts. Although this approach gives a high degree of accuracy regarding diagnosis, but the number of patients having access to this facility is limited. Hence, the development of an easily accessible method for cardiovascular disease diagnosis is highly desirable. In this research work, the past work which employs the use of Deep Neural Network (DNN) for the diagnosis of heart disease is extended, CAD for four (4) different datasets was used with Particle Swarm Optimization (PSO) assisted method for DNN to enhance the accuracy of diagnosing heart disease, which is very complex in the healthcare practices was proposed. The aim of this research is to enhance the accuracy of diagnosing heart disease. A conceptual framework to analyze CAD heart disease was developed with the end goal to improve human services partner for specialists with convenience in the advancement of treatment of disease, also integration of the PSO training algorithm to train the DNN and finally, evaluation and validation of the performance of the proposed hybrid model with benchmark model Neural Network Classifier was carried out to obtain a comparison of the proposed model to the existing classification models. The research datasets are obtained from data mining repository of the University of California, Irvine (UCI) Machine learning repository. Experimental results show that training DNN using PSO results 94%, 94.9%, 95.5%, 95.0% in accuracy for Cleveland, Hungarian, Switzerland, and VaLong beach respectively. The technique puts forth can be used in CAD detection.	Classification, Heart disease diagnosis, Coronary Artery Disease, Machine learning, Particle Swarm Optimization, Neural Network
doc3	Prof. Rasheed Gbenga JIMOH	Cloud-based IoMT framework for cardiovascular disease prediction and diagnosis in personalized E-health care	The advent of Internet technology has provided the opportunity to connect billions of computers and devices globally. The advantages offered by Internet technology have been extended to Internet-of-things (IoT). The extension of IoT to include devices in the medical domain with reference to Internet of medical things (IoMT) has improved the quality of personalized health-care services. However, the huge volume of big data generated by IoMT sensing devices in the health-care environment is of great concern. This has created several challenges including identification of effective techniques to mine this huge amount of data. Thus, cloud-based applications are playing significant roles in addressing secure data storage and efficient service delivery. IoT technology integrated into the cloud enhances health-care service delivery through effective resource utilization, storage, energy, and computational capability. However, despite the huge investment in the health-care industry, the potent	Cloud computing, Cardiovascular disease, Internet-of-things, Sensors, Health care

Figure 4.18 shows a TF-IDF vectorization result obtained while comparing a Student Query with two supervisors' publications.

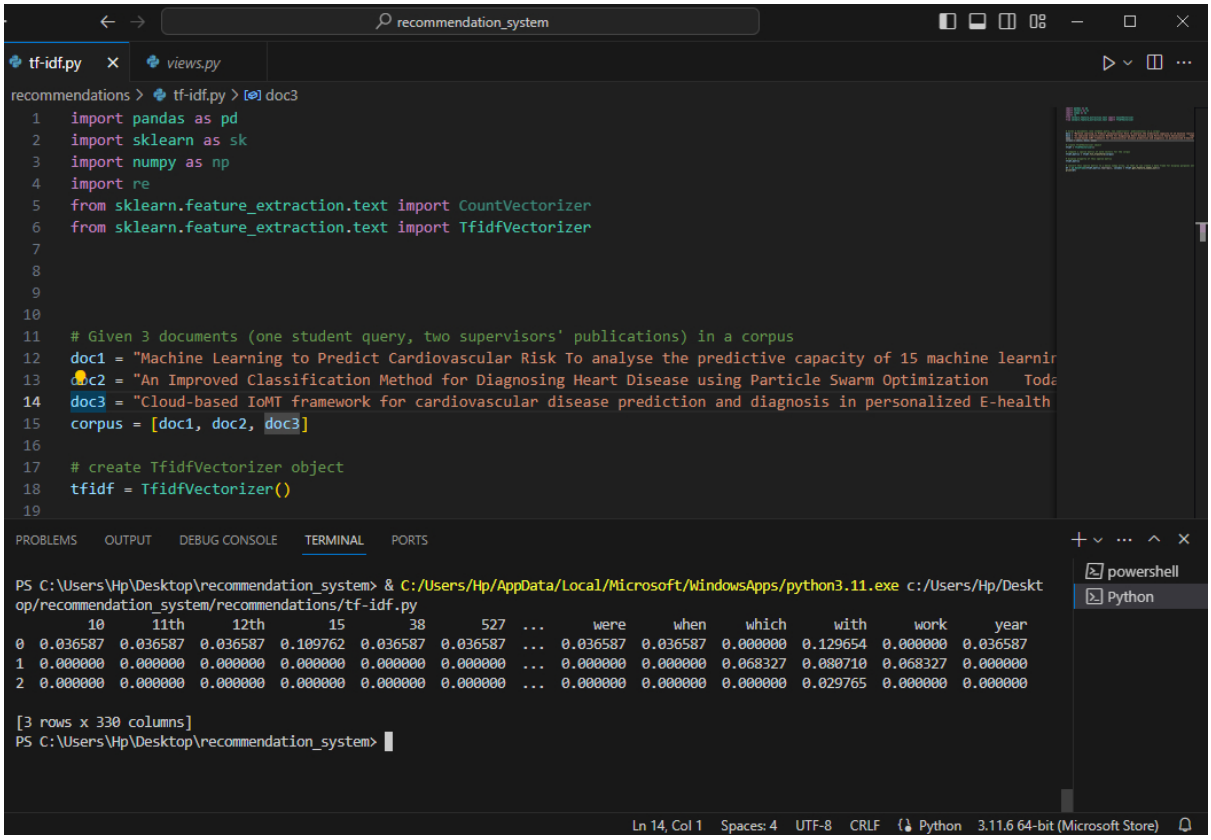

Figure 4.18 TF-IDF Vectorization Result of three Sample Documents.

The result in Figure 4.18 shows that there are three rows, which correspond to the three documents that are being compared, and 330 columns (with a few hidden columns inserted to display the initial and final few). Another thing to note is that, although there are a few non-zero values in the returned matrix, there are many zero values since certain words are absent from the provided document. Actually, a sparse matrix is the default output of the "TfidfVectorizer" function, which is a more effective method of handling a matrix with a large number of zeros. The code's "toarray()" method would enable us to create a dense array. This was done to change it from a sparse matrix to a dense numpy array so that we could only use it for display when creating a data frame.

In practice, Sparse matrix is valued over Dense NumPy array for TF-IDF for several considerations including:

i. In the event that we transform a set of raw text documents into a TF-IDF feature matrix, the majority of the values in the resultant matrix are zero since each document comprises just a small part of the whole vocabulary. Storing these resultant zero values in a dense numpy array can result in high computational memory usage, particularly if the dataset is huge.
ii. Conversely, sparse matrices just keep track of the non-zero values and the row and column indices that go with them. Because of this, storing big matrices with a substantial percentage of zero values in sparse matrices is more memory-efficient.
iii. Sparse matrices not only save memory but can also accelerate calculations since many numerical libraries are designed to work with sparse matrices and can take use of their sparsity to carry out operations more quickly. So, employing a sparse matrix is a more effective and useful approach to describe the data for TF-IDF, where the majority of the values in the matrix are zero.

4.5.5.2 Computing TF-IDF for a New Query

Upon obtaining the document-term (publication-term) matrix for a training corpus, we may utilize the "transform" function to calculate a new document's vector representation (student proposal query) by drawing on the knowledge we have acquired from the training corpus. The IDF matrix is still taken from the training corpus, but the TF matrix is entirely dependent on the new document (student proposal question) underneath. These are the causes.

1. We only compute IDF once if we think the training corpus is sufficient. This makes computing TF-IDF for a new document super-efficient.
2. If the new document will NOT be part of the training corpus, we don’t need to include it in IDF.

The screenshot of the textual data of our sample new document (consisting of title, abstract and keywords) is shown in Figure 4.19.

CLASSIFICATION OF CORONARY ARTERY DISEASE USING HYBRID APPROACH	Cardiovascular diseases (CVDs) are known globally to be among the major cause of sudden death, hence the prompt identification of CVDs could help reduce the casualties recorded via them. Diagnosis is a medical term used to describe the "process" involved that lead to the identification of a specific illness. When it comes to Coronary Artery Disease (CAD), however, this is achieved by following sophisticated and costly medical procedures in well-equipped hospitals and healthcare facilities. Furthermore, these procedures usually require only highly qualified medical experts to apply invasive methods. The number of patients who have access to this facility is limited. This research employs the use of Deep Neural Network (DNN) for the diagnosis of CAD for four (4) different datasets with Particle Swarm Optimization (PSO) assisted method for DNN. The aim of this research is to enhance the accuracy of diagnosing heart disease. Developed a conceptual framework to analyze CAD, also integrated PSO training algorithm to train DNN. Finally, evaluate and validate the performance of the proposed hybrid model with benchmark model. The research has shown that PSO is an effective evolutionary computing technique that improves the accuracy of classification. PSO selects the most optimum weight for DNN and increases the classification accuracy. The percentage improvement of the PSO hybridization to DNN are 8.8%, 11.4%, 3.3%, and 11.0% for Cleveland, Hungarian, Switzerland and ValongBeach respectively. The method put forward can improve patient diagnosis reliability and performance as it concerns CAD detection. Figure 4.20 shows the computation code for a new document and the resultant TF-IDF scores

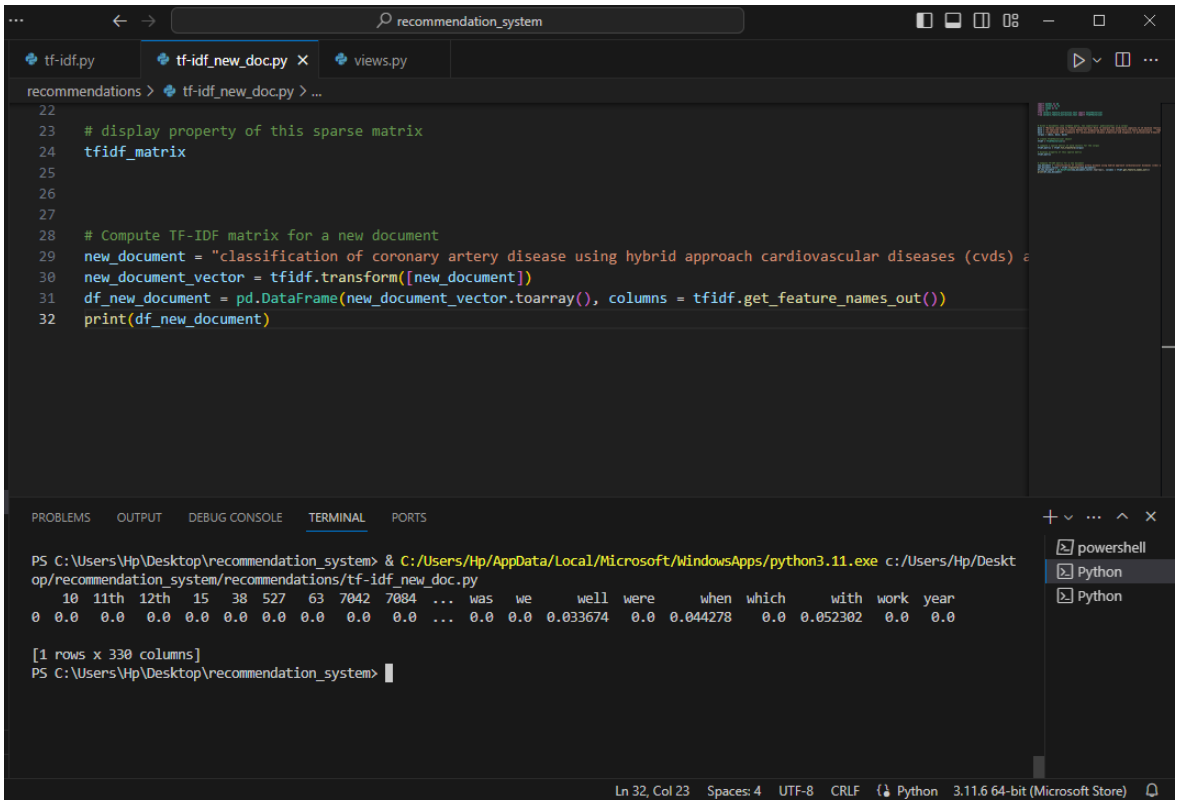

Figure 4.20 Computing TF-IDF for a new document

4.5.5.3 Computing Cosine Similarity

A common metric in information extraction and natural language processing is cosine similarity, which quantifies the similarity between two vectors. The process of calculating the cosine of the angle between the two vectors yields a score that can vary from -1 to 1 (Thongtan & Phienthrakul, 2019). A score of -1 denotes complete dissimilarity between the vectors, 0 indicates orthogonality (i.e., no correlation), and 1 indicates identicality.

Here's the cosine similarity formula for calculating similarity between two vectors:

$$\text{Cos}(x, y) = x \cdot y / (||x|| * ||y||)$$

When it comes to natural language processing, we use methods like TF-IDF to compute the cosine similarity value between two words or texts inside a corpus according to their vector

representation. The cosine similarity value in this instance can range from 0 to 1, with a value of 1 denoting perfect resemblance between two words or documents and a value of 0 denoting the opposite.

4.5.5.4 Exploring Python Libraries for Cosine Similarity

The mathematical formula makes it simple to determine cosine similarity, as was covered in the previous chapter. But what happens should one need to quickly compute the similarities but the data gets too big? Python is perhaps the most widely used programming language for these kinds of jobs, and part of its versatility comes from the large number of libraries that it has (Sukestiyarno, Sapolo, & Sofyan, 2023). The most often used Python libraries for computing cosine similarity are:

1. NumPy is a basic Python library for scientific computing that includes vector magnitude and dot product functions, both of which are required for the cosine similarity calculation.
2. SciPy: a technical and scientific computing library. Its function may determine the cosine distance, which is equal to cosine similarity minus one.
3. Scikit-learn: provides effective and straightforward tools for analyzing predictive data and includes a feature that allows for the quick and easy computation of cosine similarity.

The only library among the ones listed above that can directly determine the cosine similarity between two vectors or matrices is scikit-learn, which is a great tool for machine learning ardent supporters and data analysts. To achieve that, it offers the **sklearn.metrics.pairwise.cosine_similarity** function; we'll demonstrate how it operates using an example. Cosine similarity values between two vectors will be calculated using the **sklearn** "cosine_similarity" function.

sklearn.metrics.pairwise.cosine_similarity

`sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True)` [source]

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

K(X, Y) = <X, Y> / (||X||*||Y||)

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the User Guide.

Parameters:

X : *{array-like, sparse matrix} of shape (n_samples_X, n_features)*
Input data.

Y : *{array-like, sparse matrix} of shape (n_samples_Y, n_features), default=None*
Input data. If `None`, the output will be the pairwise similarities between all samples in `X`.

dense_output : *bool, default=True*
Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

Returns:

kernel matrix : *ndarray of shape (n_samples_X, n_samples_Y)*
Returns the cosine similarity between samples in X and Y.

Figure 4.21 Cosine Similarity Function in SKLearn (Scikit Learn, n.d.).

It is evident from the SKLearn parameters that the "cosine_similarity" function can accept both "ndarray" and "sparse matrix." It is always advised to use a sparse matrix when working with big corpuses.

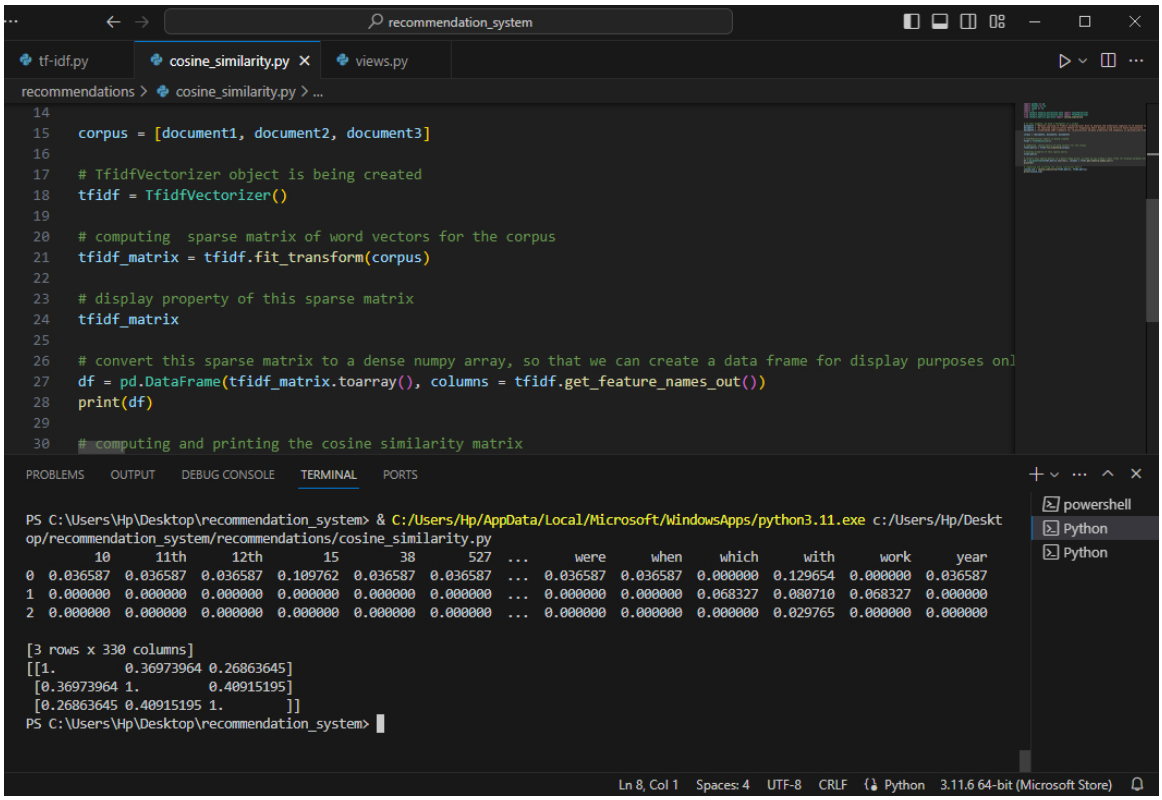

Figure 4.22 Computing Cosine Similarity

A matrix of word frequency in each of the three documents is displayed in the first result from Figure 4.22. This is where the cosine similarity is calculated, leading to the final matrix. An N by M matrix, with N representing the size of the corpus x and M representing the size of the corpus Y, would be returned by the cosine similarity. Next, the cosine similarity of two documents compared or paired from the two corpora is represented by every single element in the matrix. The contents of document1 are represented in the first column. The cosine similarity to each of the three other documents is represented by each row in the first column. In this instance, it indicates that document1 and itself have a cosine similarity score of 1. The whole diagonal equals 1 for the same reason: it shows the cosine similarity of each document to each other. The cosine similarity between the vectors of document1 and document2 is displayed in the next row of the first column; it is 0.36973964. Finally, we get the cosine similarity between the vectors of document1 and document3, which is 0.26863645. However, let us recall that our comparison is between a student project proposal query which is contained in document1 and two other documents (document2 and document 3). As a high cosine similarity score suggests a strong match, we shall order the cosine similarity values in descending order (highest to lowest). So, if we are to rank the cosine similarity scores, document2 with cosine similarity score of 0.36973964 which is higher is closer to document1 than document3 with 0.26863645 similarity score which is lower. Using the Template component of Django, the Django framework's View component sends the cosine similarity output to the user interface, where it is presented in an attractive and human-readable format.

4.6 Implications of the Results

The efficacy and dependability of this technological solution in facilitating decision-making about the selection of project research supervisors for students has been established. In this study, we analyze the wider ramifications of the findings derived from the assessment of the supervisor referral system. The practical uses and possible advantages of the system are examined within the context of academic institutions or research settings. The optimization of student-supervisor matching has the potential to enhance the research experience, optimize project results, and foster efficient collaborations. In addition, we have taken note of the obstacles and challenges encountered that need to be addressed and taken into account while adopting and executing a recommendation system of this kind for further research. Additionally, this analysis offers valuable insights into the possible utility and influence of the system's outcomes within the framework of supervisor-student matching.

4.7 Benchmark of the Results

The human brain is capable of distinguishing between few situations on the basis of minor distinctions in characteristics. This has been the case with the manual selection process as against the automated supervisor suggestion process. The model built on the algorithm was developed to simulate the brain's perception of distinctions. In our analysis, we recognized the similarity between a student’s query and one thousand one hundred and thirty-seven (1,137) research publications of supervisors. Running the data through the model and calculating the cosine similarity value, we confirmed the top three most similar to the student’s proposal input. When their cosine similarity value is close to 1, the projects are very similar and when the cosine similarity value is near zero, they are dissimilar. This project supervisor

recommendation system model is particularly valuable because it can handle supervisor recommendations effectively and scale up even with a large pool of research publications.

CHAPTER 5: SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 Summary

Automating Project supervisor selection process in academic institutions remains the key to getting the best from the student researcher and their supervisors who not only provide guidance but mentoring as well. The human brain lacks the capacity to store and recall vast amounts of data with exceptional speed and accuracy. This is particularly advantageous for making well-informed decisions and for contributing to the existing body of knowledge. The research undertaken so far on recommending project supervisors to students using Machine Learning, especially with the results obtained, has shown promising outcomes, indicating its potential to enhance research performance.

5.2 Conclusion

In order to process natural language text and extract meaningful information from a particular word or phrase using machine learning techniques, the text or string must be transformed into Word Embeddings, which are sets of real numbers (Khattak, et al., 2019). A technique in natural language processing known as "word embeddings" or "word vectorization" maps words or phrases from a lexicon to a matching vector of real numbers. This mapping is done to determine word predictions, word similarities, and word semantics. An effective technique called TF-IDF (Term Frequency - Inverse text Frequency) makes use of word frequency to

assess a word's relevance to a particular text. It is an easy way to weigh words, and as such, it could function as an incredible starting point for a lot of other activities. Creating search engines, document summaries, and other work in the fields of machine learning and information retrieval falls under this category. Using TF-IDF approaches, we calculate the cosine similarity value between two words or documents inside a corpus for the purpose of natural language processing. The cosine similarity value in this instance can range from 0 to 1, with a value of 1 denoting perfect resemblance between two words or documents and a value of 0 denoting the opposite. In this research, we used it mostly for information retrieval and machine learning tasks rather than only for search. Prior to running our data through a cosine similarity check, we could recall that TF-IDF was instrumental in the vectorization of our textual data. Text can be vectorized using TF-IDF to be transformed into a form that is more suited for Machine Learning and Natural Language Processing (NLP). Though it is a widely accepted approach for Natural Language Processing, it is not the only one available. Word embedding methods such as Bag-of-words, Word2Vec, BERT, and so on are also available (Asudani, Nagwani, & Singh, 2023). A brief comparison between Vectors and Word Embedding is made as follows:

1. **Bag of Words**
   Word frequency in a document can be counted using the Bag of Words (BoW) technique. As a result, every word in the document's corpus is represented by its vector. Bag of words and TF-IDF vary primarily in that Bag of words just represents a frequency count (TF) and does not include any type of inverse document frequency (IDF).

2. **Word2Vec**
   Word2Vec is an algorithm that ingests a corpus and generates sets of vectors using shallow 2-layer neural networks instead of deep ones. TF-IDF and word2vec differ in that the former yields a statistical measure that we can apply to terms in a document and then use to form a vector, while the latter will produce a vector for a term and then require additional work to convert that set of vectors into a singular vector or another format. Moreover, word2vec considers the context of the words in the corpus, while word-IDF does not.

3. **BERT - Bidirectional Encoder Representations from Transformers**
   BERT is an ML/NLP approach created by Google that turns words, sentences, and other data into vectors using a transformer-based ML model. The following are the main distinctions between TF-IDF and BERT: While BERT considers the context and semantic meaning of words, TF-IDF does not. Furthermore, BERT's design makes use of deep neural networks, which means that it can be significantly more computationally expensive than TF-IDF, which is not subject to these constraints.

From our result analysis, we could see that the Student Project Supervisor Recommender System leverages the text analysis and recommendation system application aspects of Cosine

Similarity. Most often, data scientists utilize cosine similarity to accomplish tasks related to Machine Learning, natural language processing, or other related initiatives. Among their applications are:

1. Text analysis, as seen in the example, is used to quantify the degree of similarity between texts and provides essential functionality for information retrieval systems and search engines.
2. Recommendation engines, which can offer related products, services or persons in social network apps depending on user preferences. As an illustration, based on the text similarity detected, suggest the following page in the product documentation.
3. Data clustering: This machine learning technique uses metrics to group or classify related data points, assisting in the process of making data-driven decisions.
4. Semantic similarity, which assesses the semantic similarity of words or texts when used with word embedding methods such as Word2Vec.

One of the most effective ways to assess or gauge how similar two documents are is to use cosine similarity. This similarity measuring tool functions well regardless of size. It can be ascertained without necessarily requiring the Sklearn module. However, the task will require additional effort. Hence, Sklearn makes this a lot easier.

By conducting an in-depth examination of the results obtained from the evaluation of the supervisor recommendation system, this study undertook a comprehensive analysis of the findings. The accuracy of the recommendations is evaluated through a comparison with the ground truth, which consists of established supervisor-student pairings that have been demonstrated to be successful. Additionally, we assess the system's ability to effectively employ content-based filtering methods utilized by recommendation systems, such as cosine similarity, to determine suitable supervisors based on project profiles. Numerous factors are considered in the methodology, such as the influence that keywords, project titles, and abstracts have on the precision of the recommendations. The aim of this study is to augment our understanding of the limitations and strengths of the system inefficiently recommending suitable supervisors for students. The functionality outlined in the requirement specifications of the recommendation system operates as intended. By employing this solution, the problem of human bias is eradicated. Supervisors who possess expertise in particular domains can derive advantages from this type of student-supervisor suggestion coupling. Therefore, it can be deduced that the research being undertaken aligns with its intended aim and objectives.

5.3 Recommendations

In as much as getting the closest match of supervisors' publications to a student's project proposal is the aim of the similarity check, TF-IDF is one of the most widely used tools for word vectorization owing to its multiple advantages, which gives it an edge over other techniques. One of the best advantages of using the TF-IDF technique in our approach to finding word similarity through word vectorization is the simplicity and ease of use which TF-IDF offers in the entire process. Its calculation is simple. Another thing to note is that it is computationally cheap. Thereby presenting it as a simple starting point for text similarity calculations via TF-IDF vectorization and cosine similarity. However, for better and improved services, some issues were observed in the course of this research, mostly relating to the

technology and methodologies employed in executing this project. A summary of a few recommendations is provided below.

1. **Investigating or Trying out Alternative Word Embeddings**
   At the same time, we should know that TF-IDF cannot help carry semantic meaning. Word importance in TF-IDF is based on the weights of such words, which in this case, cannot extract the context and the actual importance of the word or phrase. Much in the same way just like Bag of Words (BoW), TF-IDF does not take word order into account, hence compound nouns like "Prime Minister of Nigeria" will not be regarded as a "single unit." This also applies to negation scenarios where the sequence of the words "not going to school" vs "going to school" is essential. handling the phrases as a single entity in both situations involves handling "prime_minister_of_nigeria" and "not_going_to_school" with Named Entity Recognition (NER) and underscores. Due to TF-IDF's susceptibility to the dimensionality curse, memory inefficiency is another significant challenge. Remember that the vocabulary size corresponds to the length of TF-IDF vectors. While this might not be a problem in some categorization scenarios, as the quantity of documents rises, it might become unmanageable in other scenarios especially when the computing resources is low. Therefore, it could be warrant trying out some of the alternatives earlier discussed like Word2Vec, BERT etc.

2. **Enhanced Data-gathering Procedure**
   The data obtained by web scraping from Google Scholar is in its original form and may include irrelevant information. Prior to its effective use, the data must undergo many refining procedures. Therefore, there is a need for an enhanced data-gathering procedure.

3. **Availability of More data**
   The effectiveness of a project supervisor recommender system that utilizes the content-based filtering technique will be highly dependent on the content included in each item. An increase in available data from supervisors will result in improved intelligence and recommendation outcomes.

4. **Improved Computing Resources**
   It is important to note that the current hardware and software resources used in the present research implementation are capable of adequately meeting the computational requirements of the supplied data. Nevertheless, the inclusion of greater content will inevitably impact the overall execution time. Therefore, there is a need to increase resource allocation in order to enhance services as data volume increases. The more extensive the data, the longer the system will need to conduct computations. Therefore, it is vital to use a cloud server that has substantial computational capabilities.

5.4 Future Research Directions

Further research direction will be to take into consideration the observations and recommendations highlighted in section 5.3. Besides that, giving the project more value would necessitate adding more functional modules rather than just a search platform for student-

supervisor matching. Other academic components that can enhance academic research can be incorporated, which can lead to making it a world-class academic research hub with the integration of more emerging technologies, including Big Data, Cloud Computing, Artificial Intelligence, Digital Trust, etc.
